THE Vienna Medical Widow and Orphan Society has issued a most satisfactory report concerning its present condition. The funds now in its possession amount to 2,500,000 gulden. The members number 354, and the widows and orphans 136, whose pensions amount in the aggregate to 89,000 gulden. The Society's funds being in so flourishing a condition, a resolution has been passed to augment the pensions now being paid.

THE SOUTHWARK AND VAUXHALL WATER BILL.—The clause in this Bill concerning the compulsory purchase of the dust-sifting yard near the company's filter-beds at Battersea has been struck out, and in its place an agreement with the London and Brighton Railway Company, the owners of the dust-yard, is scheduled to the Bill, in which an undertaking is given to discontinue its use as a dust-sifting yard upon certain terms contained in the agreement.

ABERDEEN ROYAL INFIRMARY.—At a meeting of the Committee of Management of this institution, held on the 4th inst., for the purpose of considering the question of hospital extension, it was resolved that the sketches illustrating the Lord Provost's plan be lithographed, and, with an explanatory memorandum, circulated among the committee and medical staff. A sub-committee was elected to give effect to this resolution.

ROYAL HOSPITAL FOR INCURABLES.—The annual dinner in aid of the funds of this institution was held on the 7th inst., under the presidency of the Duke of Portland, who, in proposing the toast of the evening, made an earnest appeal for liberal subscriptions, and pointed out how essential it was that the charity should receive undiminished support. During the evening the secretary announced a list of subscriptions amounting to £3725.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY. The annual meeting of the subscribers to this hospital was held on the 1st inst., when Dr. Robertson, who presided, delivered an address, in which he briefly reviewed the work done during the past year. The number of patients admitted was 2422, of whom 2144 were sent away as improved. It was unanimously resolved that a meeting of subscribers be called to take into consideration the advisability of establishing a Hospital Saturday during the summer in aid of the institution.

Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BARENDT, FRANK H., M.R.C.S., L.R.C.P.Lond., has been appointed House-Physician to the Royal Infirmary, Liverpool.

CHAPMAN, HERBERT F., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to the Workhouse of the Richmond Union.

COCK, M. F., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Tarvey District of the Bedford Union.

EVANS, WILLIAM, M.R.C.S., L.R.Q.C.P.I., has been appointed House-Surgeon to the Royal Infirmary, Liverpool.

FINDLATER, ALEXANDER, M.B.Dub., has been appointed Medical Officer for the Second District of the Aylsham Union, and for the Alborough District of the Erpingham Union.

FRASER, JAS. THOMSON, M.B., C.M., has been appointed Honorary Physician to the Hulme Dispensary, vice G. J. Haslam, M.D., M.R.C.S., resigned.

Digitized by Google

GAILEY, JOHN A., M.D.Ed., L.R.C.P.Ed., has been appointed Medical Officer for the Leekfrith District of the Leek Union.

GEMMELL, JOHN E., M.B., C.M.Edin. (late House-Physician), has been appointed House-Surgeon to the Royal Infirmary, Liverpool.

JOHNSTON, R. M'KENZIE, M.D., F.R.C.S., has been appointed an Extra Physician to the Royal Edinburgh Hospital for Sick Children.

KNOTT, CHARLES, M.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Workhouse of the Portsea Island Union.

LISTER, CHARLES E., L.K.Q.C.P.I., has been appointed House-Surgeon to the Royal Infirmary, Liverpool.

LOE, J. S., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Second District of the Leeds Union.

LUCAS, S. A., L.R.C.S.Ed., L.R.C.P.Ed., has been appointed Honorary Medical Officer for the No. 1 District of the Liverpool Ladies' Charity and Lying-in Hospital.

OSWALD, ROBERT J. W., M.R.C.S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Seventh District of the Lambeth Parish, vice Lionel Druitt, M.D., resigned.

PEDLEY, R. DENISON, L.D.S., M.R.C.S., has been appointed Dental Surgeon to the Evelina Hospital for Sick Children, Southwark bridge-road.

PIESSE, CHARLES HENRY, M.R.C.S., L.S.A.Lond., F.I.C., F.C.S., &c., Public Analyst for the Strand District, has been appointed Public Analyst for Fulham.

PIZEY, G. F. P., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Ninth District of the Bedminster Union.

SHEPHERD, ROBERT J., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Radnorshire District of the Hay Union.

THOMAS, W. THELWALL, M.R.C.S., L.R.C.P.Ed. has been appointed House-Physician to the Royal Infirmary, Liverpool.

Births, Marriages, and Deaths.

BIRTHS.

BRADSHAW.—On the 11th inst., at Sulgrave, Banbury, the wife of J. C. Bradshaw, L.R.C.P., &c., of a daughter.

HART.—On the 10th inst., at 4, Wemyss-place, Edinburgh, the wife of D. Berry Hart, M.D., of a daughter.

LANGFORD.—On the 7th inst., at Park House, East Finchley, the wife of Phinehas Pitts Langford, M.D., of a son.

MEARS.—On the 7th inst., at 11, Northumberland-square, North Shields, the wife of Frederick Charles Mears, M.B., of a daughter.

RICHARDSON.—On the 7th inst., at Lake House, Frampton-on-Severn, Gloucestershire, the wife of Richard T. Richardson, M.R.C.S., L.S.A.Lond., of a daughter.

ROOME.—On the 6th inst., at Fluelen House, Guildford, Surrey, the wife of Henry Abercrombie Roome, M.B., of a daughter.

SANDERS.—On the 5th inst., at Church-street, West Ham, the wife of Charles Sanders, M.B., M.R.C.S., of a daughter.

SANGSTER.—On the 7th inst., at 158, Lambeth-road, S.E., the wife of Charles Sangster, of a son.

VOGAN.—On the 5th inst., at St. Matthew's, Ipswich, the wife of Jas. Norman Vogan, F.R.C.S., of a son.

MARRIAGES.

MACKERN—GIBSON.—On the 5th inst., at St. John's Anglican Church, Buenos Ayres, George Mackern, M.D., to Maria Spence, elder daughter of Thomas Gibson, of Eglinton-crescent, Edinburgh.

STEWART—BAILEY.—On the 28th ult., at the Parish Church, Marylebone, by the Rev. Page Roberts, M.A., Incumbent of St. Peter's, Vere-street, William R. H. Stewart, of 41, Devonshire-street, W., elder son of William E. Stewart, of 16, Harley-street, W., to Bessie Elford, elder daughter of George H. Bailey, of 9, Cavendish-place, W.

DEATHS.

BOYCOTT.—On the 12th inst., at Montagu-square, Thos. Boycott, M.D., F.L.S. (formerly of the Mint, Calcutta), aged 70.

BREMNER.—At Strand-terrace, Walmer (after a few hours' illness), John Traill Urquhart Bremner, Inspector-General, R.N., aged 64.

LEWIS.—On the 7th inst., at Bywood, Woolston, T. R. Lewis, M.B. (F.R.S. elect.), Surgeon-Major, Army Medical Staff, aged 44 years.

LYONS.—On the 7th inst., Isidore I. Lyons, L.R.C.P., M.R.C.S., L.S.A.Lond., L.D.S., late Surgeon-Dentist, St. Bartholomew's Hospital, and of Queen Anne-street, Cavendish-square, W., aged 44 years.

OWEN.—On the 7th inst., at Belvedere-road, Upper Norwood, Harvey Kimpton Owen, M.D., F.R.C.S., L.S.A.Lond., in his 71st year.

PARRY.—On the 10th inst., at Lancaster-terrace, Regent's-park, Richard Parry, M.D., aged 79.

SEALY.—On March 9th, at Nelson, New Zealand, William Byers Sealy, M.D. (formerly of Swindon, Wilts), eldest son of the late Lieut.-General B. W. D. Sealy, of Cleve Dale, near Bristol, aged 63.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, May 17.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

SOCIETY OF ARTS.—8 P.M. Dr. B. W. Richardson: Animal Mechanics (Cantor Lecture).

Tuesday, May 18.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.

PATHOLOGICAL SOCIETY OF LONDON.—8 P.M. Mr. Eve: Adenoma and Adenosarcoma of Ovary.—Mr. Hutchinson: Adenoma of Palate.—Mr. Hutchinson, jun.: Neuroma of Parotid.—Dr. Acland and Mr. Ballance: (1) Noma; (2) Actinomycosis in Man.—Dr. Payne: Erythrasma.—Dr. Silcock: (1) Gangrene of Lung; (2) (for Dr. H. Jones): On the Vessels in Meningitis.—Dr. West: Mediastinal Tumours.—Dr. Turner: Miliary Tubercle in Pulmonary Artery.—Dr. Sharkey: Perforation of Vermiform Appendix.—Dr. Sainsbury: Tubercular Mass in Suprarenal.—Dr. Hale White: Case of Peripheral Neuritis, Myelitis, and Pachymeningitis.—Mr. Bilton Pollard: (1) Duct Papilloma of Breast; (2) (for Mr. C. Heath): Secondary Epithelioma of Lower Jaw.—Mr. Battle: (1) Osteochondrosarcoma of Breast; (2) Osteochondroma of Thigh.—Dr. Hadden (for Mr. Paul): Rupture of Aorta. Card Specimens will be shown by Drs. Kidd, Silcock, Sharkey, and Hadden, and Messrs. Battle, E. H. Fenwick, Churchill, and E. Crookshank.

SOCIETY OF ARTS.—8 P.M. Mr. Ernest Hart: Japanese Art Work.

Wednesday, May 19.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

SOCIETY OF ARTS.—8 P.M. Prof. Leonard Waldo: Watchmaking by Machinery.

Thursday, May 20.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Dewar: The Alkaloids.

HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. E. Downes: Treatment of Leprosy and Sciatica by Nerve-stretching.—Dr. R. Maguire: On the Albumens of the Urine.

Friday, May 21.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Mr. William Bassie: The Waters derived from the Bagshot Beds considered as Drinking Supplies.

SOCIETY OF ARTS.—8 P.M. Capt. Richard Carnac Temple: Everyday Life of Indian Women.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Ballance will give a Demonstration in Bacteriology, to include the Cultivation of various Micro-organisms in Nutrient Media, together with Microscopical Preparations of the same.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Sir John Lubbock: The Forms of Seedlings, the causes to which they are due.

Saturday, May 22.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Ernst Pauer: How to Form a Judgment on Musical Works.

SOCIETY OF ARTS.—3 P.M. Prof. George Forbes: Electricity

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

DAMP TOBACCO.

SOME startling statements with reference to the adulteration of tobacco by excessive moisture were made by Mr. Macfarlane in the House of Commons last week. Of some samples of bird's-eye tobacco which he had caused to be examined, No. 1 sample, at 5*s.* per lb., contained from 5 to 8 per cent. of water; No. 2, at 4*s.* 8*d.*, from 10 to 14 per cent.; No. 3, at 3*s.* 10*d.*, from 21 to 26 per cent.; No. 4, at 3*s.* 4*d.*, from 40 to 45 per cent.; No. 5, at 3*s.* 2*d.*, from 45 to 50 per cent.; and No. 6, at 3*s.* 1*d.* per lb., contained from 55 to 60 per cent. of water. These three lowest qualities represent three-fifths of the whole tobacco consumed in this country, and almost exclusively that which is smoked by the working classes.

Dr. Alex. Hill will find, on reference to our number of the 1st inst., p. 851, that the fact has already been announced in our columns.

"BONE-SETTERS AND THE PROFESSION."

To the Editor of THE LANCET.

SIR,—In your last issue, p. 908, appeared a short note bearing the above heading. Your opinion there expressed gratifies me, inasmuch as it upholds the course I found it necessary to take quite recently with a patient. The latter, a young girl, has suffered from strumous disease of the knee-joint for about eighteen months. As it was not improving so quickly as her parents would have liked, they, without my knowledge at the time, took her to a bone-setter in the neighbourhood, who told them the usual story, and said he could cure her. The mother, however, did not think her daughter could bear the pain of having the joint "put in," and asked me to go with them to the setter of bones in order to administer chloroform. This I at once firmly refused to do, and gained for myself the name of being very unkind, and at the same time lost a patient. I, however, felt convinced that I had acted rightly, and your opinion strengthens me in my belief. I am, Sir, yours faithfully,

May 8th, 1886. X.

THE MORPHIA HABIT.

To the Editor of THE LANCET.

SIR,—I should advise your correspondent, "Young Practitioner," to urge his lady patient addicted to morphia injecting to apply for admission into a suitable institution. From my experience I can affirm it is the best course and the most reliable. Many such cases have been successfully treated and cured.

I am, Sir, yours truly,

May 10th, 1886. J. ST. THOS. CLARKE, M.B.Lond.

THE COST OF THE SMALL-POX.

THE following extract from a recent speech of the President of the Grand Trunk of Canada Railway is interesting:—

"Of the £83,000 which we lost in the last half-year of 1885, £50,000 may be computed to be owing to the outbreak of small-pox at Montreal, and £3000 to the loss of emigrant traffic. The disease commenced in Montreal in February, 1885. The conductor of a Pullman car arrived at Montreal with the disease upon him, and as there was no special hospital to which he could be taken, he was conveyed to a regular general hospital, and very kindly treated. From that one case the disease spread with most alarming rapidity. The municipal authorities had not the necessary experience to enable them, in the first instance, to deal with such an outbreak of contagious disease; but afterwards it was vigorously attacked, and ultimately stamped out. But if the Grand Trunk Railway Company have lost £50,000 owing to the small-pox, the mercantile community of Montreal has been a far heavier loser. Goods sent from Montreal were actually returned as being infected goods, and at one time no one would buy anything from the city. The commerce of the whole district was paralysed, and Montreal was boycotted. Even the province of Quebec itself was isolated. The province of Ontario established a system of inspection, and there was a medical inspection also established at various points in the United States. No one travelled by our trains who could help it, the through traffic by way of Canada was driven into United States channels, the Grand Trunk trains were all shunned as being infected, and wherever passengers were discovered care was taken immediately and promptly to vaccinate them and to fumigate them thoroughly. As yet we have hardly recovered from that state of things. It followed us up to January, 1886, when the Montreal carnival could not be held in consequence, and from the carnival in past years we have always derived a good deal of traffic. It was useless to attempt to hold a carnival."

Dr. Ashby.—Probably next week.

"AN UNUSUAL CASE OF CONGENITAL MALFORMATION."

To the Editor of THE LANCET.

SIR,—In your issue of April 10th, p. 722, Mr. Salter describes a case of unusual congenital malformation, but where a post-mortem examination was not allowed. On Sunday, March 21st, I met with a case presenting somewhat similar symptoms, and the result of the post-mortem examination was rather interesting. The child (a female) was born about 2 A.M., and looked quite healthy, except that the abdomen was unusually distended, and on my visit in the evening the nurse drew my attention to the large size of the abdomen and stated that the child had been very sick. I requested her to give it a teaspoonful of castor oil, and when I called again on the Tuesday I found that the oil had not operated and that the sickness was getting much worse, the vomit becoming black and offensive. I tried an injection, but it succeeded in bringing away only a few very small lumps of fæces. The vomiting became more and more severe and the child died on Thursday morning, having lived a little over four days. At the post-mortem examination the stomach was found normal and the small intestine for about three feet was also normal, but here it ended in a blind extremity, which was greatly distended. Then, quite separate from all this, and not attached to it in any way, were coils of very small intestine several feet in length and not measuring more than a sixth or an eighth of an inch in diameter. This passed on into the right iliac fossa, and there forming the ileo-cæcal valve it continued in the course of the large intestine on to the rectum, its diameter in any part of its course not measuring more than a sixth of an inch. Doubtless the explanation of the non-development of this part of the intestine is simple, but the breach of continuity of the small intestine just about three feet from the stomach is not so easy of elucidation. Perhaps some of your readers may offer an explanation.

I am, Sir, yours faithfully,

Southwick-street, W., April 20th, 1886. OWEN PRITCHARD, M.D.

THE LEPER HOSPITAL AT BERGEN.

IN the *Sunday Magazine* for the present month is a description, by Mrs. Chas. Garnett, of the Asylum for Lepers at Bergen, the largest of the three institutions of the kind in Norway. Together they are capable of accommodating 800 patients, the number of inmates in 1880 being 617. The poor sufferers seem to be well cared for, and their lives made as pleasant by cheerful surroundings as their pitiable condition will admit of. Some of the rooms visited by the writer, however, were rendered intolerable by the want of ventilation, to which the lepers appear to have a deadly antipathy. In vain do the doctors in the morning throw open the windows; they are again closed as soon as opportunity offers. Most of the patients find a measure of relief from the monotony of their dreary existence by engaging in some kind of handicraft in the large workrooms set apart for the purpose. Segregation being recognised as the only effectual means of lessening the prevalence of leprosy, and of finally annihilating it, the Norwegian Government, we are told, is seeking to obtain powers to make the isolation of the sick compulsory, either in the national asylums or in their own homes.

Dr. Gilbertson will find the announcement on page 901 of our last issue.

THE CONSUMPTION OF TEA.

ACCORDING to some statistics recently published by an Indian contemporary, it appears that the people of Great Britain are considerably behind other nations in the average consumption of tea per head of population. The Australians come first with 7·66 lb. per head; the New Zealanders next with 7·23 lb. per head; while the people of Great Britain, though appearing third in the list, consume only 4·90 lb. each. Newfoundland and Canada come next, while in the United States the consumption is only 1·30 lb. per head; and in Russia, which is always regarded as a great tea-drinking country, the consumption is only 0·6 lb. per head. Belgium, Sweden, Austria-Hungary, and Spain consume less than the other European nations; but there is not one nation on the Continent, with the exception of Holland, in which the annual consumption exceeds 1 lb. per head.

COCAINE AND SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—The subject of sea-sickness having been again opened by your correspondent, "Surgeon R.N.," I venture to send you the following two cases and accompanying observations without the usual apology.

My own observations have led me to distinguish two distinct forms of *mal de mer*, and a third intermediate or hybrid one. A certain proportion of the cases of sea-sickness will be noticed to occur almost immediately upon the vessel leaving port, and the number of these cases and the severity of their symptoms are always proportionate to the extent of the rocking. In these patients all purely "bilious" symptoms are conspicuous by their absence—that is to say, the skin and conjunctivæ are not jaundiced, there is no diarrhœa, the urine is not abnormally coloured, and the ejecta do not contain bile. If the retching is very severe, some bile may be regurgitated through the pylorus and appear in the vomit, but in small quantities only. I have always looked upon these cases as of purely nervous origin, possibly, as your correspondent suggests, due to jarring of the semicircular canals. I should, however, before definitely adopting this view, be glad to hear his explanation of the fact to which my attention was long ago called—namely, the great relief experienced in some cases by the application of firm support to the hypogastrium. I can recall a severe case which was much benefited by the tight application of the usual obstetric binder. Acting upon the theory that this form of vomiting is of the nature of a nerve reflex, I have been in the habit of prescribing anodynes. Chloral has been distinctly beneficial; but, on account of its taste, it is superseded, in my estimation, by cocaine. The following two cases are fairly illustrative of its usual action in my hands. They occurred on one of the Orient steamers in September last. Soon after leaving, the weather became very severe, the hatches were battened down, and only a few male passengers were allowed on deck by special permission.

CASE 1.—Miss B—— commenced to vomit two hours after leaving the Thames, and was very sick for an hour, when (at noon) she was given one-third of a grain of hydrochlorate of cocaine in a teaspoonful of water and orange syrup. She felt relieved almost immediately, and did not vomit again till 4 P.M., when a second dose was administered. She now became drowsy, and slept till 10 P.M., when she awoke, and was sick again. She then asked for another dose (the third). She fell asleep soon after taking it, and slept soundly all night. Next day she continued in a drowsy state. In the evening she sat down to dinner, eating a fair meal apparently. The weather was slightly less severe, but very rough, and though it continued so for the rest of the voyage she had no return of sickness.

CASE 2.—Mr. B—— had been sick all the first day, and at 6.30 next morning was given one-third of a grain of hydrochlorate of cocaine, which he immediately rejected. At 9 A.M. a second dose was given. He retained this, and slept till 1 P.M., and was very drowsy till 4 P.M., but not sick. He got up to dinner and partook of soup and fish and came off deck afterwards. The weather was still very rough, and continued so, but he had no return of sickness.

On future occasions I shall give a quarter of a grain, one-third seemingly being unnecessarily large. Another class of cases I have noticed occur usually at the expiration of twenty-four hours or more after leaving port, and they do not seem to be much affected by the rolling of the vessel. These patients have a typically "bilious" appearance. The skin and conjunctivæ are yellow, the tongue is furred, there is usually some bilious diarrhœa, the urine is high coloured, and the vomit always contains bile. One sees usually more of these patients, for they have not the tendency to lie down which the others have, but seem, on the contrary, restless. Their condition seems to be due to the stimulating effect of the sea air upon the secretion of bile, the effect no doubt being heightened by the sudden cessation of accustomed exercise, and, perhaps, a sharpened appetite and consequent over-eating. The same symptoms, in a less degree, are observable in persons newly arrived at the sea-side from some inland locality, and may more properly be designated "sea biliousness." Small frequent doses of an effervescing saline are usually sufficient to relieve them of their distress. The most difficult to treat are those whose symptoms give one the impression of partaking of the above-described two conditions combined. A man who feels a little qualmish has, of course, the finishing touch added when his gall-bladder and duodenum become distended with bile. I usually to these administer cocaine in an effervescing form.

I am, Sir, your obedient servant,

Regent's-park-road, May 10th, 1886. W. COOPER ADAMS, M.B. Lond.

THE SANITARY CONDITION OF TONQUIN.

IN a work on Tonquin by Dr. Challan de Belval, Chief Medical Officer of the French Expedition, which has just been published in Paris, a considerable space is occupied by a description of the hygienic—or unhygienic—conditions of the country, which is stated to be damp and unhealthy. The houses are also insanitary, the clothing of the people insufficient, and their food "detestable," so that their low and debilitated condition is easily accounted for. Malaria is very frequent, and is met with in very grave forms, more often in woody and mountainous districts than in the delta. The most common and most fatal disease after malaria seems to be dysentery. The author saw many cases of abscess and hydatid of the liver. As to cholera, it may be said to be endemic, with frequent and severe epidemic exacerbations. Typhoid fever proved fatal to many of the French soldiers. Small-pox is very prevalent, and is said to kill more than half the children. Tuberculosis, scrofula, rheumatism, and leprosy are all common. Syphilis, however, is rare among the natives, except in the vicinity of great European centres. Notwithstanding all the hygienic disadvantages, the author believes that Tonquin will develop into a fine colony, decidedly superior to Cochin China.

Mr. William Tebb.—We regret that we cannot find space in THE LANCET for anti-vaccination arguments. Life is too short, and small-pox too real and near a risk.

A. B. had better apply to the registrar for the desired information.

"KISSING THE BOOK."

To the Editor of THE LANCET.

SIR,—Dr. Mowat can hardly be aware that the suggestion he has made is wholly impracticable, since it is the duty of the court usher, who administers the oath, to see that witnesses place the Testament against their lips; otherwise they are not sworn at all. It is the practice with many medical witnesses here to kiss the open book; and though this is, strictly speaking, a privilege of Royalty, I have never seen or heard of its being objected to. The mode of administering the oath in Scotland is much more solemn, as well as being free from this objectionable practice of kissing a book which, however sacred, is too often the reverse of clean. I believe that in the Channel Islands the oath is administered in a mode similar to that practised in Scotland, and I hope that we may live to see this method made uniform throughout the United Kingdom. It is somewhat unfortunate that this subject, solemn though it ought to be, is just one of those in which there is only one step from the sublime to the ridiculous. But if any Member of Parliament were to take up the matter, he would I am sure meet with both support and gratitude. The general adoption of the Scotch method would relieve many witnesses from any fear of infection—a fear which, I believe, is by no means chimerical; would be more of a solemnity and less of a farce than the present mode, and might also, in the case of many witnesses of the lower orders, cause a decrease in the crime of perjury.

I am, Sir, yours faithfully,

Liverpool, May 8th, 1886. FRED. W. LOWNDES.

HOSPITAL ETIQUETTE.

To the Editor of THE LANCET.

SIR,—I should be glad to have an expression of your opinion on the following case. I am house-surgeon of a provincial infirmary, and, according to the rules, am the head of the house. The matron is untrained, and her chief duties are those of a steward in a large London hospital. One morning recently I began my visit, and entered one of the female wards, where I found the matron. After waiting some time in the expectation that she would withdraw, I requested her with the utmost civility to leave the ward until I had made my round. This she flatly refused to do, and she continued to go from bed to bed until she had spoken to every patient, I meanwhile standing idle until she left the ward with an air of injured dignity amidst the titters of the patients. I have previously been resident at two large metropolitan hospitals, where the *trained* lady matrons always, as a matter of routine, left the wards the moment the house-surgeon entered them; and I would ask, as a matter of hospital etiquette, whether I was not justified in considering myself aggrieved in the above circumstances.

I am, Sir, yours faithfully,

May 11th, 1886. M.B. EDIN.

*** It is no part of the duties of the matron of a hospital to attend the house-surgeon in his rounds.—ED. L.

RINGWORM IN A NEW-BORN INFANT.

To the Editor of THE LANCET.

SIR,—In your issue of April 10th I notice a letter from "Surgeon," citing a case of ringworm in a new-born infant. On March 18th I attended a lady in her confinement, and it was found by the nurse that the child had a small ringworm, about as large as a threepenny piece, on the abdomen, just above the left groin. When my attention was directed to it some days afterwards it was as large as a shilling, and gradually increased until it had attained an area half as large again. Under treatment it is improving.

I am, Sir, yours truly,

April 30th, 1886. PHYSICIAN.

COPPER SALTS.

WRITING in a French Pharmaceutical journal, M. du Moulin states that sulphate of copper has been given by him to dogs in quantities of a drachm, and even more, without fatal results. Vomiting was produced; but after the lapse of some hours the animals appeared none the worse. The subacetate of copper also, which is commonly looked upon as a very poisonous substance, was given to dogs and rabbits daily in doses of from eight to fifteen grains for six weeks without causing any very serious results. The animals vomited for the first few days, but afterwards the tendency ceased and did not recur. The oxide and carbonate of copper have been administered to rabbits for a year without hindering growth. Compounds of copper with the fatty acids gave similar negative results. M. du Moulin has prescribed the sulphate of copper repeatedly in infantile sickness without producing any poisonous results.

A. W. L.—Tænia mediocanellata—the commonest form in this country—is derived from beef and (occasionally) mutton; tænia solium from pork. These two species are easily distinguishable.

HOODED GIG.

To the Editor of THE LANCET.

SIR,—In answer to a "Country Doctor," I may say I have used a hooded gig many years, and am now using a second. My experience is that the draught is much less than in a brougham. In meeting a strong wind the draught is felt at the back of the neck; and when it rains with a strong head wind, thorough protection from wet is not secured unless the head be brought well forward. I never have the hood up when driving against a strong head wind. I am, Sir, yours faithfully,

May 8th, 1886. M.D.

Surgeon.—We think—supposing that our correspondent's letter accurately represents the facts—that A and B have just cause to complain of the behaviour of C, who in courtesy ought to have made any complaints he had to make to A and B, the resident medical officers of the workhouse. We regret we have not space to insert the letter.

COTTAGE HOSPITALS.

To the Editor of THE LANCET.

SIR,—I am anxious to obtain the rules of cottage hospitals, and shall feel obliged by anyone sending them to me.

I am, Sir, yours faithfully,

Bocking, Braintree, Essex, May 10th, 1886. THOS. TAYLOR, M.R.C.S.

ERRATUM.—In the annotation headed "A Chemical Analysis Desirable," page 887, "Sutherland" has been printed in error for *Litherland*.

ABSTRACT OF A

Clinical Lecture

ON THE

CONNEXION BETWEEN SCARLET FEVER AND HEART DISEASE.

By HENRY ASHBY, M.D. LOND., M.R.C.P.,

PHYSICIAN TO THE GENERAL HOSPITAL FOR SICK CHILDREN, MANCHESTER; LECTURER ON DISEASES OF CHILDREN, VICTORIA UNIVERSITY.

GENTLEMEN,—In taking the medical histories of our patients here, we often find that parents will insist that their children "have never been well since they had scarlet fever," and there is often much truth in this, inasmuch as this fever is apt to leave behind it not only enfeebled health, but various sequelæ which may be a source of annoyance or even risk for many years. On the other hand, an attack of scarlet fever, with its danger to the patient and inconvenience to the household, is likely to impress itself on the memory of parents, and is apt to get the discredit of after-coming troubles, with the production of which it may have had no share. Scarlet fever has been blamed in a casual and indefinite sort of way with giving rise to heart disease, and it may be worth while for us to review the subject by the light of the clinical and pathological records of nearly 900 cases which have passed through the scarlet fever wards of this hospital during the last five years.

The first question that naturally suggests itself when considering this connexion is—What relation does rheumatism bear to scarlet fever, or rather what part does the virus of the fever play in exciting or predisposing to an attack of rheumatism? Misconceptions here are very easy, for the commonest form of joint affection which complicates scarlet fever in children is a form of synovitis which is doubtfully rheumatic in character and is not often accompanied by endocarditis. In twenty cases of scarlatinal synovitis which have come under my care, in no one was there evidence of endocarditis, though in one there was a temporary pericarditis and in another pleuro-pericarditis. These attacks differ in several ways from acute or subacute rheumatism; they are more fugitive in character, rarely recurring or returning to a joint when once it has left, and exhibiting an especial tendency to attack the synovial membranes on the backs and palms of the hands, finger-joints, soles of the feet, and cervical vertebræ. The attacks mostly take place from the seventh to the ninth day of the fever. Nearly all these attacks of synovitis occur in cases in which the temperature is maintained longer than usual on account of severe inflammation of the cervical glands or ulceration of the tonsils or palate. These attacks of synovitis are certainly commoner in some epidemics than in others. But, apart from synovitis, attacks indistinguishable from true rheumatism are liable to occur at the end of the third or during the fourth week, much at the time that nephritis is liable to supervene. My own experience is that this post-scarlatinal rheumatism is commoner in young adults than in children, and indeed I believe it to be rare among the latter. Endocarditis is by no means uncommon in these attacks. It also happens that an attack of scarlet fever occurring in a patient convalescent from rheumatism has given rise to a relapse. I have seen this on several occasions among children who have been admitted to the general wards for subacute rheumatism, and who have contracted scarlet fever. In three of my cases pericarditis or joint pain occurred within a few days of the onset of the fever. In what way the poison of scarlet fever determines a relapse in these cases I am unable to say; I can only record the fact.

There is another complication of scarlet fever which is, I believe, a not infrequent cause of cardiac lesions, and that is nephritis. Probably a certain amount of dilatation of the left ventricle, with more or less compensatory hypertrophy, occurs in most cases of scarlatinal nephritis of any severity, and may certainly take place within a week, as can be demonstrated by examination of the apex beat. Both endocarditis and pericarditis may take place, and embolism occasionally occurs. Peri-endocarditis may also accompany the pyæmia which occasionally complicates scarlet fever; but as these cases are almost certainly fatal, it can hardly be said to produce heart disease. It will perhaps be worth while to refer separately to the different lesions which may occur.

Pericarditis.—The tendency to the production of pericarditis in uncomplicated cases of scarlet fever is not great. Litten has stated that dry pericarditis of short duration, without complaint of pain or any very obvious symptoms, is commoner than is supposed; and in this I am inclined to agree with him, as on several occasions I have noted a pericardial rub, lasting a few days and again disappearing without any signs of effusion. In two of my cases of scarlatinal synovitis there was a pericardial rub detected, and in one there was evidently some local pleurisy. In three cases of undoubted rheumatism already referred to, two of which were convalescent from an attack when scarlet fever supervened, suffered from pericarditis within a week of contracting the fever, and all three died in the course of a few weeks. All had suffered from chronic heart disease prior to the attack. Pericarditis also occasionally accompanies both pleurisy and mediastinitis in connexion with the septicæmic state so common in severe cases of scarlet fever. Thus it not infrequently happens that, in fatal cases attended with much suppuration of glands and cellulitis about the neck, pus burrows downwards from the deep cervical glands into the anterior mediastinum, and an effusion of lymph takes place in this situation, and possibly also a suppurative pericarditis or empyema. If recovery take place in such cases, this inflammatory process in the mediastinum may lead to matting and cicatrisation of the fibrous tissue and consequent pressure on the great vessels, especially the inferior vena cava and hepatic veins, giving rise to impeded hepatic circulation and perhaps hypertrophic cirrhosis. Pericarditis occasionally occurs in nephritis.

Endocarditis.—There is very little post-mortem evidence of endocarditis occurring in cases of scarlet fever dying during the course of the disease itself. I have examined the heart in upwards of 100 fatal cases of scarlet fever, and have never seen either endocarditis or pericarditis in any case uncomplicated with nephritis. The edges of the mitral valves are mostly irregular and nodular, and more or less thickened, probably in consequence of a swelling of the fibrous tissue elements between the layers of endocardium, but the surface of the latter is smooth and shiny, and has evidently not been the seat of endocarditis. The above condition is by no means uncommon in other febrile states, and is not peculiar to scarlet fever. This experience, I believe, agrees with others, though both Litten and Henoch have published cases in which ulcerative endocarditis was found post mortem associated with caries of the petrous portion of the temporal bone, purulent meningitis, thrombosis of veins, and pyæmic abscesses, complicating scarlet fever. If the post-mortem evidence is negative, what facts can be gathered from clinical observations? It must have occurred to all who have seen much of scarlet fever, or indeed of any febrile disease in children, to note murmurs, or at least abnormal cardiac sounds, during the height of the fever, which for the most part are systolic, are heard best in the mitral area, but also at the base, but not in the axilla. The first sound at the apex is frequently elongated, or not so clear and distinct as normal. Some authors have not hesitated to claim these bruits or murmurish first sounds as evidence of a scarlatinal endocarditis. Thus Picot, in the article on Scarlatina in the *Nouveau Dictionnaire de Médecine et Chirurgie*, says, in speaking of endocarditis, "the attacks are light, readily escape observation, and are easily healed." When some years ago I began to constantly examine the hearts of scarlet fever patients, I was struck with the frequency of abnormal heart sounds, and believed at first they were due to endocarditis. But the evidence afforded by the post-mortem room, and the careful following up of cases during convalescence, convinced me that the murmurs heard were only functional, and, whatever might be their cause, they were not due to an organic lesion. There are, however, a few cases on record in which the evidence is tolerably strong that endocarditis did occur during the course of, or during convalescence from, an attack of scarlet fever. Thus Litten[1] relates the case of a man aged twenty-one, who was admitted to hospital on the eleventh day of an attack of scarlet fever;

[1] Charité Annalen, vii., p. 136.

Digitized by Google

he appears at this time to have been convalescent, and his principal complaint seems to have been perforation of the membrana tympani; fourteen days afterwards he complained of pain in the chest with feverishness, and the day following a pericardial friction sound was heard; three days later this had disappeared, and a systolic bruit was heard at the apex; this latter persisted, and two years later the patient was evidently suffering from chronic valvular disease. It must, however, be noted that the endocarditis in this case occurred during the fourth week, which is the usual time for post-scarlatinal rheumatism to supervene. Henoch mentions in his lectures the case of a boy, aged six years, who developed a systolic bruit at the end of the second week of an attack of scarlet fever, which remained for two months and then disappeared.

I have already referred to the fact that in cases of scarlatinal synovitis, although bruits were heard in several of them, these were only temporary, and afforded no sufficient evidence of endocarditis. Endocarditis does unquestionably occur in the post-scarlatinal rheumatism, which sometimes supervenes during the third or fourth week of the attack of the fever, and when the patient is fully convalescent. In two cases of malignant endocarditis under the care of my friend, Dr. Massiah, of Didsbury, in which the joint symptoms were slight but the cardiac severe, which followed during convalescence from scarlet fever, fatal results occurred in the course of four or five weeks. Ulcerative or malignant endocarditis, either with or without joint pain, seems occasionally to follow scarlet fever.

Endocarditis is undoubtedly a not infrequent complication of scarlatinal nephritis. I have noted this post mortem in three cases. In one of my cases an anæmic girl of nine years was admitted with albuminuria and œdema of face, with a history of a previous attack of scarlet fever. There was præcordial pain, dyspnœa, and a loud, almost musical, systolic bruit; there was also an enlarged spleen and intermittent fever. Shortly before her death she suffered from severe pain in the head, paresis of the right arm, optic neuritis, and retinal hæmorrhages. At the post-mortem the kidneys were enlarged, the cortex pale and fatty; there was extensive endocarditis, the mitral valves and posterior wall of the left auricle being covered with granulations, and a small aneurysm, evidently embolic, on the left middle cerebral artery. In a second case, which died three weeks after the onset of the nephritis, a deep ulcer was found involving one aortic valve; no bruit had been heard during life. In a third case, of a girl aged six years, who died three weeks after the onset of the nephritis, both pericarditis and endocarditis, the latter consisting of nodules of fibrin on the aortic valves, were found. A pericardial friction sound, but no distinct murmur, was heard during life. In addition to the post-mortem evidence of the existence of endocarditis in scarlatinal nephritis, there is the hardly less convincing evidence afforded by clinical observation, more especially that of the onset of hemiplegia due to embolism coming on during convalescence. Such cases have been recorded by Bristowe,[2] T. Barlow, Semple, and Finlayson. In Semple's case[3] the hemiplegia seems to have supervened some twelve weeks after the onset of the nephritis, and when the patient had been up and about. It is important to note that murmurs were not to be heard in several of these cases. In several of my cases of nephritis bruits have been detected during life and endocarditis diagnosed, but no endocarditis found at the post-mortem, only a dilated left ventricle. In other cases which recovered murmurs were also existent, and which were present when they left the hospital. It is not certain what is the cause of endocarditis in acute nephritis; the uræmic condition of blood seems to predispose to inflammation of serous membranes—as the pleura, pericardium, and peritoneum; and the high tension in the bloodvessels, by bringing about a "banging" action of the valves, would seem to give rise to a greater irritation of the endocardium than during their normal closure.

Degeneration of the muscular walls. — In most fatal cases of scarlet fever the muscular walls of the heart are pale and flabby, and the endocardium on the musculi papillares and interior of the ventricles is mottled in appearance, presenting typical "tabby cat" degeneration. The paleness of the walls is due to the presence of minute particles of fatty or granular matters in the muscular fibres, a change very similar to that occurring in all the organs. I have not seen any cases with the indurated or leathery condition of the heart muscle described by Litten.

Dilatation and hypertrophy of the heart without valvular lesions.—In long-continued pyrexias the muscular walls of the heart are apt to be damaged, and the cavities in consequence to become dilated. That this occurs to some extent in scarlet fever is probable, such hearts being found pale and flabby, and the cavities apparently having yielded more or less when contracting on their contents, though I have never seen any marked dilatation or hypertrophy. When, however, in addition to a disturbed nutrition of the muscular fibres, the blood-pressure rises as it does in acute nephritis, there is a frequent and very marked yielding of the walls of the heart, so that the cavities become dilated. As the high tension in the vessels affects all the cavities more or less, they are all found more or less dilated, though naturally the cavity to suffer most is the left ventricle. The amount of hypertrophy which follows depends upon the chronicity of the case and the nutritive powers of the patient. The full significance of this cardiac dilatation and its tendency to produce dyspnœa and sudden death has only been recognised by recent writers, such as Goodhart, Friedländer, and Silbermann. In the most severe cases of nephritis, dilatation may take place very quickly, so that it may be possible in the course of a few days or weeks to see a marked change in the position of the cardiac impulse, the impulse being first noted inside the nipple line, then actually on the line, and later still outside. This dilatation may occur without the presence of a murmur, though in other cases I have noted murmurs when the post-mortem showed there was no endocarditis. There can be little doubt that this dilatation occurring during an attack of nephritis may be perfectly recovered from, the cavities returning to their normal size after the nephritis has passed away and the health completely restored. This is illustrated by one of my cases, a boy of eleven years, who was admitted with acute scarlatinal nephritis, in whom the cardiac dulness was increased in breadth, the apex beat being diffused in the sixth and seventh spaces, partly external to the left nipple line, and who had attacks of orthopnœa, especially at night, with a cantering action of the heart. Later there was some basic pneumonia, much enlargement of the liver, and temporary amaurosis. There could be no doubt that both sides of the heart were dilated. He finally recovered under the use of digitaline and ether given subcutaneously. The albuminuria gradually disappeared, and when seen two years and a half afterwards he was doing heavy work in a shop, and an examination of his heart showed that the cardiac dulness and apex beat were normal. In another case, that of a boy aged eleven years, who was admitted with acute nephritis, after having walked a couple of miles to the dispensary, dyspnœa set in a few hours after admission, which quickly ended fatally. At the post-mortem all the cavities of the heart were dilated, and there was no endocarditis. In another case, that of a boy aged six years, admitted with acute nephritis, the cardiac dulness extended one inch to the left of the nipple line; the impulse was diffused, partly in the epigastrium and partly in the left nipple line, and there was a well-marked murmur heard at the apex and in the axilla. Two days after admission he was seized with urgent dyspnœa, vomiting, pallor of the face, and much distress, and died in a few hours. At the post-mortem both sides of the heart were dilated, the walls of the ventricles were very thin and pale, and there was no endocarditis or valvular lesion. Such cases are far from uncommon, cases being reported by Goodhart, Silbermann, and Baumgarten, and I have myself seen nine or ten, which ended fatally. Various authors have ascribed the symptoms and fatal issue to œdema of the lungs or thrombosis of the pulmonary artery. That general œdema is very often present is certain, but it is not always so, and œdema of the lungs is clearly not the primary cause of the fatal issue, but is the result of the gradually failing heart. The pathology of such cases is tolerably clear: the nutrition of the heart suffers in consequence of the uræmic and anæmic condition of the blood, while it has to carry on the circulation with an obstruction to the passage of blood through the arterioles of the kidney and elsewhere. The heart is like a badly fed and over-driven horse, who first staggers under the weight of its load, and then suddenly falls exhausted beneath it.

To sum up the connexion of scarlet fever with heart disease I may submit the following:—1. In uncomplicated cases of scarlet fever lesions of the heart are very rare.

[2] Theory and Practice of Medicine, 4th edition, p. 1042 (note).

2. Endocarditis is quite exceptional in scarlatinal synovitis; pericarditis occurs more frequently. 3. Acute or subacute rheumatism occasionally supervenes during convalescence from scarlet fever; an attack of scarlet fever may also be the exciting cause of a relapse; in such attacks peri-endocarditis is frequent. 4. Peri-endocarditis occasionally occurs in scarlatinal pyæmia. 5. Dilatation without valvular disease very frequently occurs in scarlatinal nephritis; peri-endocarditis and embolism are by no means uncommon.

TWO CASES OF AMPUTATION OF THE PENIS FOR EPITHELIOMA,

BY PEARCE GOULD'S MODIFICATION OF THIERSCH'S OPERATION.[1]

BY FRED. B. JESSETT, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL.

THE following two cases were admitted under my care at the Cancer Hospital. They were both men over seventy years of age, and in very enfeebled health. One man was operated upon on Dec. 8th, 1885, and the other as lately as Feb. 9th of this year.

CASE 1.—J. W——, aged seventy, a compositor, was admitted into the hospital on Dec. 5th, 1885, suffering from epithelioma of the penis. Five years ago he had ulcers on his legs; otherwise he has enjoyed fairly good health until two years since. No specific history. Has been a hard drinker. Father and mother died of old age; an uncle on the father's side died of cancer of the mouth. Seven months previously the patient first noticed a small red pimple on the lateral aspect of the middle of the penis, which has grown very rapidly until the present time. Experiences very great pain, but has no difficulty in micturition.

State on admission.—He has a large fungating and offensive growth on the penis, reaching quite to the root; the glands in the groins are slightly enlarged—none, however, larger than a small bean; and as these are so in both groins, probably they are only sympathetic, but not diseased. The patient is much debilitated in health, and has chronic bronchitis; he is most feeble and decrepid; notwithstanding this, however, as the disease is giving him so much pain, and there is considerable discharge of a most offensive character, it was decided to remove the diseased organ.

On Dec. 8th, the patient, being fully under the influence of ether, was placed in the lithotomy position, the legs being supported by Clover's crutch. The pubes being shaved, a circular incision was made round the root of the penis, and another incision extended from the lower part of this along the line of the raphé of the scrotum well into the perineum, and the two halves of the scrotum separated quite down to the root of the penis. A catheter was now passed into the bladder, and the corpus spongiosum divided about an inch and a half above the bulb by passing the blade of a knife between it and the corpora cavernosa. The catheter being removed, the urethra was divided from behind forwards. The corpus spongiosum with the urethra were now dissected carefully from the body of the penis as far back as the triangular ligament. This part of the operation being finished, I seized the penis and dragged it well forwards and downwards, and with a pair of scissors divided the suspensory ligament and tissues around, as far as the rami of the pubes. I then with a periosteal raspatory separated the crura from their attachments. The whole body of the organ now being removed, I caught up and ligatured the few bleeding vessels. The hæmorrhage, however, in both this and Case 2 was quite insignificant. The urethra was next slit up on its under side for about half an inch, and carefully stitched to the lower angle of the wound. Having washed the wounded surface out with a solution of carbolic acid, and dusted the raw surface over with iodoform, I inserted a drainage-tube in the lower angle, and united the margins of the wound with a few interrupted sutures and a continuous horsehair suture. The parts were then dusted over with iodoform and enveloped with salicylic wool, and the patient returned to bed.—Dec. 9th: Patient has passed a good night and micturated twice. No catheter was introduced into the bladder, and the man has complete control over his urine.—10th: He passed a bad night, due to excessive coughing, and also has great pain in passing urine, but no difficulty. Temperature last night 101°, but has fallen this morning to 100°. The scrotum is becoming discoloured (ecchymosed). He continued to improve from this time, and on the 15th the stitches in the upper part of the wound were removed. In the centre of the incision is a small slough, but the rest of the wound looks healthy, and at the upper part it has united by the first intention; there was some slight cellulitis, which has, however, all disappeared, and the whole part looks healthy, with the exception of the urethra and corpus spongiosum, which are sloughing.—28th: Wound has quite healed excepting where the slough came away at the lower angle; here there are healthy granulations; the corpus spongiosum has entirely sloughed away.—Jan. 10th: There is a hard painful swelling between the urethra and anus, evidently containing pus, probably due to urinary infiltration; this was freely opened, and a quantity of pus escaped; pus also flowed from the orifice of the urethral opening, and on injecting a solution of sulphurous acid into one opening it escaped by the other. The opening in the perineum gradually closed, and the urine now flows in the newly formed channel. The man is now quite well, but owing to the sloughing of the corpus spongiosum there is some contraction of the urethra; this, however, I do not at present intend to interfere with.

May 12th.—I saw this man a few days since. The wounds are almost imperceptible. He passes urine in a good stream. There is no sign of recurrence, and the glands in the groins have disappeared.

CASE 2.—J. W——, aged seventy-four, butler, was admitted into the Cancer Hospital on Feb. 8th, 1886, with epithelioma of the penis. He has been a healthy man. No specific history. Mother's relatives phthisical. Has had contraction of the prepuce all his life. No history of cancer in his family. On account of the contraction of the prepuce he had it slit up some twelve years ago. Six months since the patient noticed a small spot near the frænum, and consulted a medical man, who applied caustic to it, which appeared to reduce the growth, but it rapidly increased afterwards. Has had a good deal of pain and irritation from it.

State on admission.—There is an ulcerating mass extending over the glans penis and partly down the body of the organ; it does not interfere with micturition, but is very painful. The base of the mass is hard, and the surrounding parts deeply indurated. The inguinal glands are not affected. He has an old inguinal hernia on the right side, for which he wears a truss.

On Feb. 9th, the patient being placed under ether, the penis was removed by an operation similar to that described in the last case.—10th: There was a good deal of oozing during the night, and this morning there is a quantity of blood-clot between the lips of the wound. Temperature 101°. Patient can pass urine quite freely, but complains of frequent desire to micturate.—11th: Scrotum a good deal discoloured. There is no sign of any sloughing. The patient still complains of great pain and frequent desire to micturate.—12th: Temperature normal. Has slept well. Pain during micturition less, and desire not so frequent. Swelling of scrotum subsiding, and natural colour returning. The stitches at the lower part of wound have given way, and a small slough has formed.—18th: Some considerable sloughs have come away from the wound, and there is a good deal of discharge.—24th: The lower part of the wound now looks healthy and is granulating well. Micturition causes no pain, although the desire to pass urine is somewhat frequent; but probably this is not more so than is to be anticipated in a man of his age.—March 15th: Discharged. Wound healed, and the patient is able to pass urine without difficulty.

Remarks.—These two men are now convalescent. The patient in Case 1, when I first saw him, was a miserable-looking man, completely worn out by chronic bronchitis, pain, and the profuse stinking discharge from his penis. His cough, which was most troublesome, has now considerably improved, and, in fact, he hopes shortly to return to his employment. Mr. Pearce Gould's case, reported in THE LANCET of May 20th, 1882, and these two are the oldest patients on whom I have been able to find this form of operation performed, and although in the first case I hesitated before subjecting the man to such a severe operation, yet I felt that if left alone he would gradually succumb to the disease. The best plan of dealing with the urethra in all cases of amputation of the penis has been a vexed question from time immemorial,

[1] Paper read at the meeting of the Medical Society of London, March 22nd, 1886.

Digitized by Google

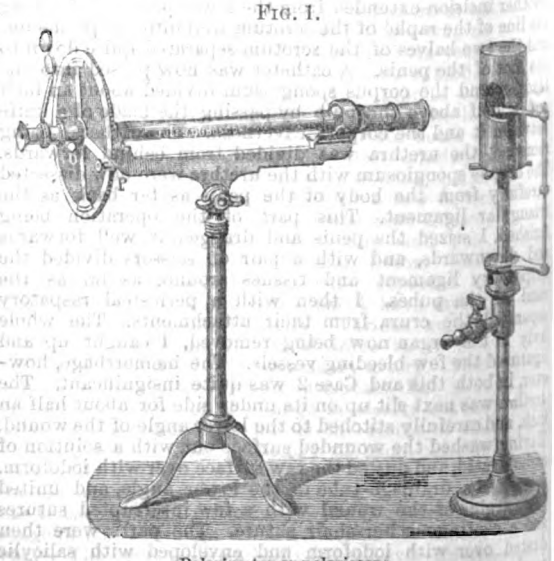
and although many suggestions have been made so as to prevent its retracting when dealt with in conjunction with the stump of the amputated penis, it was not until Professor Thiersch, of Leipsig, adopted the plan of bringing the urethra through an opening in the perineum that any real advantage was obtained. The operation, as suggested and practised by this surgeon, was planned with a view of splitting the scrotum down the middle, sufficiently far to allow of his dissecting the urethra and corpus spongiosum away from the body of the penis, and then making a button-hole in the perineum about an inch and a half in front of the anus, bringing the divided urethra through the opening and fixing it there by a few sutures. He then contented himself with slicing the corpora cavernosa off close to the pubes and stitching up the wound. This operation has been performed by many English surgeons[2] with marked success, and undoubtedly the position of the urethra in the perineum has been the source of the greatest comfort to patients who have had the misfortune to be obliged to part with this important organ. Sir William Mac Cormac in February of last year showed a man at the Medical Society of London in whom he had amputated the penis in this fashion, and he has lately published five other cases, in all of which the most favourable results have been obtained. Mr. Wheelhouse, of Leeds, has also recently published two cases in which he had operated in a similar manner with equally happy results. We have, then, eleven cases here recorded of this method of amputation, all of which have been successful.

Mr. Pearce Gould, however, is the first surgeon who seems to have recognised the importance of removing the whole corpora cavernosa from their attachments to the rami of the pubes and ischium, and in order to accomplish this he suggested a slight but important modification of Thiersch's method, so as to enable him to have sufficient room to more readily detach the crura of the corpora cavernosa. He therefore adopted the plan of splitting the scrotum completely from the root of the penis to the perineum and as far back as the triangular ligament. By this means the body of the penis is brought into view for its whole length, and after about an inch and a half of the corpus spongiosum with the urethra are dissected from the cavernosa there is no difficulty in detaching the crura from their attachments by means of a raspatory. The urethra then is split along the lower border and fastened to the lower angle of the incision, as described above. I think this operation of Mr. Gould's is founded on more scientific grounds than that of Thiersch, because there is infinitely less likelihood of the disease recurring in the cicatrix or stump if the whole of the corpora cavernosa are removed than if the root of the penis is allowed to remain, and I consider this operation is a very decided advance in the surgery of these parts. In my first case the corpus spongiosum sloughed and caused great difficulty in keeping the opening for the passage of the urine patent. This may probably be accounted for by the age and debilitated condition of the man. It is a noticeable fact that both patients had complete control over their bladders from the time of the operation, and in neither case did I introduce a catheter at the time of the operation.

One important question, I think, arises in these operations of the removal of the penis in middle-aged or young men, and that is, What course should the surgeon adopt in regard to the testes? Mr. Wheelhouse has drawn attention to this point in the two cases he has recorded: in one the testes were involved in the disease, and were removed at the same time as the penis; in the other, the testes were free from disease and were left. These two men were inmates of the hospital at the same time, and occupied adjoining beds, and therefore had an opportunity of comparing notes. The one in whom the testes were removed made an uninterrupted recovery, and expressed himself as feeling completely relieved in every way; the other, however, although he made a good recovery, was a martyr to the physiological action of his testes, which were a constant source of annoyance to him, and he still remains a prey to desires which he can never gratify. I think everyone will admit that the condition of the former patient was certainly more satisfactory and perfect than the latter. This perhaps is one drawback to the special form of operation now being discussed, as by the old method, so long as any portion of the penis remained, the question of removing the testes need not arise. On the other hand, however, I am strongly of opinion that the immunity from recurrence in the stump is of far more importance than this minor inconvenience to the patient. Therefore, in performing amputation of the penis in men under fifty years of age, this point should be fully laid before them; and as the risk to life by loss of the testes is not materially increased, we should rather advise their removal. As to the advantages of bringing the urethra through the perineum, they are so manifest that they require little comment from me. There is no doubt that the comfort of the patient is considerably enhanced by having the opening of the urethra in such a position that he can sit down in comfort, and micturate without the urine passing over his scrotum and thighs. In one of Sir W. Mac Cormac's cases the patient even got over the difficulty of having to sit down to urinate, as he contrived a tin pipe like the spout of a teapot which fitted comfortably underneath between his legs, and there was not the slightest difficulty in passing urine in the ordinary manner. No doubt, therefore, surgical instrument makers can easily contrive something of a similar fashion.

I think the operation as suggested by Mr. Gould and practised by me in these two cases has this advantage over Thiersch's operation—that it enables the surgeon to make a complete dissection down to the triangular ligament, thus giving ample room for detaching the crura of the corpora cavernosa from their attachments, allowing the deep parts to be thoroughly drained, and preventing any fear of bagging of serum or pus. Moreover, undoubtedly the fear of retraction or contraction of the urethra is not nearly so great as in the old operation of amputating the penis by a sweep of the knife, or of the more modern fashion of forming flaps to cover the end of the stump, and leaving the urethra sufficiently long to pass through and be fastened to them.

[2] I am reminded by Mr. Davies-Colley that Professor Humphry, of Cambridge, practised a similar operation to that described by Thiersch as early as the year 1870.



ON THE

COMMON ORIGIN OF DIABETES AND THE URIC ACID DIATHESIS.

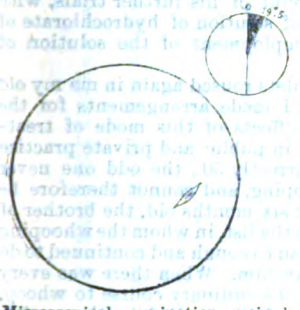
BY DR. DEBOUT D'ESTREES,
OF CONTREXÉVILLE.

THAT diabetes and the uric acid diathesis have a common origin is not a new idea. The subject has been discussed by many writers, some upholding, others opposing, the theory. My own experience classes me with the first, because in all the cases of diabetes brought under my notice at Contrexéville since my appointment in 1868 I have seen the sugar during treatment give place to an excretion of uric acid.

FIG. 1.

Polarimeter or polariscope.

The examination of each sample of urine has on every occasion been carefully made by myself with both microscope and polarimeter (see Fig. 1), the latter instrument giving the proportion of contained sugar with the greatest



Digitized by Google

accuracy. Some of my last observations were made with Dr. Cruise, President of the College of Physicians of Ireland; and it is, indeed, at his suggestion that this paper has been written.[1]

Dr. Marchal de Calvi, in a work entitled "Observations sur les Accidents diabétiques," published in 1864, writes: "The most obvious factor in the morbid *processus* of diabetes is the influence of the uric acid diathesis," and my experience at Contrexéville leads me more than ever to share his opinions as to the connexion of diabetes with gout and gravel. The following cases will, I think, corroborate these views. They are taken from my last season's note-book, and refer exclusively to patients sent me by British and Irish physicians.

Mr. V——, a gentleman fifty-six years of age, came to me on July 8th, 1885. He had been suffering for three years from polyuria and polydipsia. His sight was affected, there was a loss of power in the lower limbs, and an almost total insomnia existed. There was no gout or gravel in his family. For six months before his arrival at Contrexéville he had been under the care of Dr. Chepmell, and the treatment, mainly dietetic, had reduced the quantity of urine

FIG. 2.

Microscopical examination: a single epithelial cell. Polariscopical examination: 19·5° = 42·90 grm. of sugar per 1000.

FIG. 3.

Microscopical examination: some uric acid crystals. Polariscopical examination: 5° = 11·00 grm. of sugar per 1000.

FIG. 4.

Microscopical examination: abundant crystals of uric acid. Polariscopical examination: negative; no sugar.

passed in the twenty-four hours from four pints and a half to three pints, with at the same time a fall in the specific gravity from 1045 to 1038. The amount of sugar per litre was 42 grammes (4·2 per cent.). There was no albumen and no deposit. The treatment consisted in drinking from one to two litres of water from the Pavillon spring in the course of the day, with the addition after July 15th of cold douches of short duration. On the 17th an examination of the urine passed at bedtime and on getting up in the morning showed a specific gravity of 1024, and ten grammes per litre (1 per cent.) of sugar, while with the microscope *crystals of uric acid were discovered for the first time.* (See Figs. 2, 3, and 4.) The quantity of mineral water consumed daily was doubled, and on August 3rd the polarimeter showed that no sugar existed, but a red deposit visible to the naked eye afforded evidence of the excretion of a large quantity of uric acid. The patient was then entirely free from thirst and insomnia, and before leaving Contrexéville was able to walk eight miles a day. A better idea of these changes will be obtained by reference to the drawings taken from nature by means of the camera clara.

If space permitted I could quote a great many cases like the above, but this would involve a vain repetition. I wish, however, to insist particularly on this clinical fact, that in *all* the cases of diabetes which I have treated at Contrexéville the diminution or disappearance of the sugar has coincided with the appearance or with the increase of uric acid crystals in the urine. At the same time the glycosuria may coexist with the excretion of uric acid, and of this clinical truth the following two cases are illustrative:—

Mr. M——, aged forty-six, a man of robust health, and weighing ninety-nine kilogrammes, came to me on the 2nd of June in consequence of pains in the loins, which had recurred at irregular intervals during the six preceding years, the attacks lasting five or six days. For two years he had suffered from violent thirst. Micturition was frequent, five or six times during the night. The urine on June 4th was amber-coloured, slightly cloudy, of specific gravity 1040, contained 10 per cent. of sugar, and the microscope showed that the cloudy deposit, simulating mucus, consisted exclusively of minute crystals of uric acid. On June 11th the specific gravity was 1022; quantity of sugar 2·5 per cent. On the 18th the specific gravity was 1015; no sugar, but abundant red uric acid sediment. The nocturnal micturition had ceased.

Mr. X——, an Australian gentleman, was sent to me by Dr. Cruise with the following diagnosis: Irritable bladder; no stone; a little sugar in the urine. Dr. Cruise, who came to Contrexéville during this patient's stay, was able himself to verify the results of my analyses. In the first sample examined on Aug. 12th, globules of pus, a few epithelial cells, and crystals of uric acid were seen under the microscope. On the 28th of the same month crystals of uric acid alone remained, all traces of sugar having disappeared, the specific gravity being 1015.

That a low specific gravity does not always imply absence of sugar, nor a high specific gravity prove its presence, are clinical facts of which I have seen many illustrations. Without going further back than last summer, I may refer to a patient of Dr. Ramskill's who came to Contrexéville on July 11th with urine of a specific gravity of 1031, containing crystals of oxalate of lime, but no sugar. By the 29th of the same month the specific gravity had dropped to 1015, and crystals of uric acid alone were visible.

Another case came under my observation on July 12th—a patient of Dr. Hermann Weber. The specific gravity of the urine was 1030; crystals of oxalic acid were also present, but no sugar; and here by Aug. 3rd the specific gravity had fallen to 1012, and uric acid crystals alone were to be seen.

On July 17th, in a patient of Dr. Matthew Baines, who was non-diabetic, I found a specific gravity of 1029 and a number of oxalic crystals. A like specific gravity existed in the urine of a patient sent me by Mr. Buxton Shillitoe on August 14th, and in both cases the high density disappeared and uric acid took the place of the octohedral crystals. I also saw the same change under the influence of the waters last season in a lady sent me from Paris; here the specific gravity was 1034, with oxalate of lime, but no sugar.

The inference must not, however, be drawn that a high specific gravity always accompanies crystals of oxalate of lime, for in a patient sent me last year by Sir Andrew Clark, suffering from marked symptoms of oxalic gravel, the specific gravity was only 1020, though the microscope detected quantities of oxalate of lime. Nor must it be inferred that a low specific gravity is incompatible with the presence of sugar—e.g., the case of a lady in whom in 1879, during an obstinate attack of bronchitis, Dr. Wilson Fox had detected diabetes, and made the subjoined urinary analyses in 1880 at Contrexéville:—

		Sp. gr.	Albumen.	Sugar.
Aug. 20th	Morning	1022	0·40	22·0 grammes
	Evening	1026	1·30	35·20 "
" 26th	Morning	1015	0·30	15·40 "
	Evening	1017	0·50	17·60 "
Sept. 3rd	Morning*	1010	Traces	None
	Evening	1010	0·25	Traces

* Uric acid crystals appeared under the microscope.

This case tends to show that a comparatively low specific gravity does not always counter-indicate the presence of sugar, but as I purpose making a special clinical study of the subject of albumen in the urine, I will not here enter upon its discussion.

[1] I am aware that Dr. Cruise of Dublin is about to read a paper before the Academy of Medicine in Ireland on the Estimation of Sugar in Urine by the Polariscope, and I expect that his communication will shortly be published.

ON THE NATURE OF WHOOPING-COUGH;

WITH A DESCRIPTION OF A NEW MODE OF TREATMENT INTRODUCED BY PROFESSOR MONCORVO, OF RIO DE JANEIRO, AND ITS PRACTICAL RESULTS.

BY WILLIAM H. BARLOW, M.D.,

CONSULTING PHYSICIAN TO THE DISPENSARY, GENERAL HOSPITAL AND DISPENSARY FOR SICK CHILDREN, MANCHESTER AND PENDLEBURY.

(*Concluded from page 917.*)

THE idea of a parasitic origin for whooping-cough has been for a long time floating in the minds of physicians; and so long ago as 1867 I had myself, led to that way of thought by the then new doctrines of Lister and the results of his treatment of deep abscesses &c., treated large numbers of out-patients at the Manchester Hospital for Sick Children with carbolic inhalations, both in the form of spray (using a solution of 2 or 3 per cent.) and as vapour. But though the success was marked, circumstances occurred which caused me to discontinue this mode of treatment: the inhalation of the spray could not be effectually carried out, except under the supervision of a medical attendant, and in the case of hospital out-patients this was of course impossible; while the vapour was frequently allowed to become so strong as to produce great irritation, not only to the patient, but also to the healthy inhabitants of the house. Even when carefully regulated it was oftentimes too irritating to be borne, and in cases where there was bronchitic complication it was necessary at once to intermit the treatment. Indeed, the fatal result in a case complicated with broncho-pneumonia in a little relative of my own, and which seemed to me to be in a great measure due to the irritation caused by the vapour, was the immediate reason of my ceasing to use this means; this death took place in 1868. The practice common among the people of towns, of taking their children to the gas-works to inhale the vapours from the purifying tanks, points also in the same direction, and it is a common practice to inhale the fumes of gas-tar for the same purpose. Parrot[1] has used phenate of soda for the same purpose, and considers the carbolic acid as heroic, *if not specific*, in whooping-cough. Many other writers have used the carbolic acid and carbolates all over the world, and the results have always been favourable as to the whooping. In Belgium, Tordeus[2] has used benzoate of soda with success. Keuster has employed inhalations of thymol. The salts of quinine have been used with more or less advantage by many, particularly in America. Huebner found benefit from salicylate of soda, and Hildebrandt[3] from inhalations of petroleum vapour. All these experiences point in one direction, that of the parasitic origin of this disease; and all are more or less subject to one drawback, that when they are strong enough to be effectual as parasiticides they become injurious as irritants. It was this fact which led me so long ago to renounce the use of the most effectual among them, and it was this which led Professor Moncorvo, more happily, to that research which induced him to employ the substance I have already named, and the discussion of which I am about to enter upon. It is a congener of carbolic acid, which, however, is free from the irritating qualities of that substance. This is Resorcine, a substance which fills a position in the class of aromatics very near to that of carbolic acid. Andeer[4] and Callias and Dujardin-Beaumetz[5] have borne witness to the remarkable effect which resorcine exercises upon the organic ferments, even in small doses; and indeed the latter assert its superiority to carbolic acid in that respect. There are also the advantages of the much greater solubility of resorcine, of its less caustic properties, of its very slight odour, and of its infinitely less toxic qualities—all which, together with the scarcely less important fact of its slightly sweet taste, combine to render it much more suitable as a topical application than carbolic acid. These properties had led Professor Moncorvo to employ it for internal administration in diarrhœa, dysentery, and other diseases of children, even infants at the breast, before he essayed its employment in whooping-cough. But he lays great stress upon the perfect chemical purity of the specimens of the drug to be employed, and he prefers to use it in an aqueous solution of 1 per cent., which is the strength that I have used. The first applications, which are made by means of a large camel-hair pencil or a swab to the supra-glottic portion of the pharyngeal lining, to the opening of the glottis and the pharynx, generally increase the violence of the chinks and their number; but that soon subsides, and in the course of one, two, or three days, the patients tolerate the application, and the chinks rapidly decrease in number. It should be applied at intervals of two hours, both night and day, unless the child sleeps, in which case it should not be disturbed. In his treatise Dr. Moncorvo gives thirty cases, and of eighteen of these he gives complete details; and in a further account in the *Archivio di Patologia Infantile* of Naples for the months of May, July, and September, 1885, he gives a further series of forty cases; many of these were complicated with bronchitis and broncho-pneumonia, and many also were in children with strumous or syphilitic cachexia. In no case was the complication a cause of any difficulty in the treatment, a statement in marked contrast with the use of carbolic acid, or other of the parasiticide reagents which have been previously mentioned. The last post from Brazil brought me a little additional treatise from the pen of the Professor, containing an account of his further trials, with the result of the application of solution of hydrochlorate of cocaine previously to the employment of the solution of resorcine.

The perusal of these pamphlets roused again in me my old interest in the question, and I made arrangements for the study of the disease and the effects of this mode of treatment. I collected altogether in public and private practice 51 cases, or perhaps more correctly 50; the odd one never arrived at the stage of whooping, and cannot therefore be counted, but it was a child of six months old, the brother of one of the children included in the list, in whom the whooping was fully established. He began to cough and continued to do so for several days before I saw him. When there was every appearance of proceeding in the ordinary course to whoop, the solution was well and carefully applied by the mother to both children; the elder, who was whooping every half-hour, was so far improved that the whoops fell to three or four in the twenty-four hours; and the younger, the child in question, lost his cough altogether, and never whooped at all. Thus, then, I only count 50 cases, of which I have given a list, and from which I gather the following facts. There were in these 50 cases 19 males and 31 females, clearly showing the predominance of the disease in the female sex. The ages showed under six months 5 cases, under twelve months 5, under eighteen months 4, under two years 6, under three years 10, under four years 5, under five years 3, under six years 4, and under seven years 3. The length of time under treatment is: under two weeks, 2; under three weeks, 5; under four weeks, 11; under five weeks, 5; under six weeks, 8; under seven weeks, 10; under eight weeks, 2; under nine weeks, 3—total, 46: leaving 4 cases of which no account can be heard, but of which Mr. Mills, the assistant medical officer, reports that the probabilities are that they were cured: "I think you may say they are all cured: if they had died, I should have known about it." The total duration of disease is: under two weeks, 1; under four weeks, 2; under five weeks, 8; under six weeks, 3; under seven weeks, 4; under eight weeks, 5; under nine weeks, 2; under ten weeks, 4; under eleven weeks, 3; under twelve weeks, 3; under seventeen weeks, 1; under twenty weeks, 1; under twenty-two weeks, 1; under twenty-three weeks, 1—total, 46. Thus the average length of treatment, of the 46 cases of which we have an accurate account, is five weeks and a half, within a fraction; while the total average duration of the disease is eight weeks and a half; but it is extremely likely that both these figures would be reduced by the inclusion of the four cases which we are unable to trace. Dr. Charles West[6] gives, from an observation of twenty-five cases, ten weeks as the average duration of the disease; but it is so extremely variable in its duration that this cannot be considered as otherwise than a very favourable calculation; and I am inclined to believe that the figures I have stated above show the effect of treatment, and that the true average is much higher than it is placed by Dr. West.

I have in the foregoing statistics given the bare facts,

without any gloss or enthusiasm; I have placed no weight upon the individual cases, many of which have been very markedly affected by the treatment, but have trusted to averages, and where there has been any defect of observation or of knowledge have omitted them; but I think that we are justified in saying that there has been no fatality among these fifty cases, as had either of the four cases of which we have lost trace ended fatally we should have heard of it at the dispensary. Yet there were several severe cases among them, complicated with bronchitis, broncho-pneumonia, &c., such as Nos. 4, 5, 14, 16, 18, 19, 29, and 36; and of great debility, as Nos. 15, 26, and 39 (the last being a case in which paracentesis thoracis had been performed for empyema examination nothing special was to be seen; these specimens were from cases which had been for some days under the treatment, but in those which were taken from cases where the whoop was fully established, but which had not yet been submitted to treatment, the appearances are thus described by Mr. Broadbent: "Examined with one-twelfth immersion, with B eye-piece magnifying about 800 diameters, and the preparation stained with methyl aniline violet, it shows numerous nuclei of pus-corpuscles and some shreds of fibrinous material and a few epithelial scales. In some of the latter there are numerous small micrococci, arranged singly in chains and in groups (zoogloea); similar micrococci are also seen in other parts, but in much smaller numbers;

* Was better, and began again September 1st.

eighteen months before, and where the wound remained open and discharged pus for over six months); or cachectic, as in Nos. 3, 31, 41, and 42. It is in these cases that this treatment seems to evince a decided superiority over most other modes, as it does not cause any irritation, and need not be intermitted for the purpose of allowing other forms of treatment to be carried on, nor does it interfere in any way with such treatment. I think, therefore, that these results justify the recommendation of Professor Moncorvo; and I have also, by the aid of the well-known skill of Mr. J. Broadbent, been enabled to corroborate the statements of the Professor as to the microscopic appearances and the effects of this treatment upon them. Thus, in the earlier specimens of expectorated matters that were submitted to microscopic the epithelial scales seem to be the chief seat of the organisms." This, it will be seen, exactly confirms the description of Professor Moncorvo.

In the light of this experience and these observations we may, then, agree with the following conclusions:—"1. That whooping-cough is to be classed among the diseases which are caused by the irritation excited by the presence of parasites. 2. That it is due to the presence of micrococci, which proliferate in large numbers upon the lining membrane of the larynx and pharynx, and which infiltrate the epithelial cells, which seem to be the preferential seat of their growth and increase. 3. That resorcine in a solution of the strength of 1 or 2 per cent., applied directly to the mucous surfaces concerned, has been found, in all cases in

Digitized by Google

which it has been employed and the results watched, to rapidly reduce the number of chinks, to reduce their intensity, and finally to lead to the cure of the disease." This last word "cure" is a bold one, but if the first and second propositions are held to be proven, then there can be little doubt that it is properly used. For if there are no other diseases *cured*, yet certainly those which are due to the irritation of a parasite are cured when that parasite is destroyed.

Lastly, the mode of application by means of a brush or swab is not the only mode in which it may be made; perhaps by some of the recently used instruments for applying medicated spray to the interior of the larynx and the adjacent parts of the throat (as that recently described by Dr. Miller of Windsor and by Dr. Hodgkinson) it may be applied yet more effectually than by the methods adopted by Professor Moncorvo and myself. And, again, it is not finally proven that resorcine is the best application that may be found. Perhaps in its near congener, orcine, we may have a still better agent for this purpose, for we find in a note by J. J. Andeer in the *Gazetta Medica Italiana-Lombardia* of July 4th, 1885, that "Orcine possesses almost all the physical properties of resorcine; but while the latter is caustic in large doses, orcine is never more than astringent and antiseptic." This seems to point the way to further experiments, but meanwhile I ask my readers to put to the proof the facts I have placed before them, and to make from them the deductions to which they lead. To guard against misunderstanding, I wish to add that, while sharing to a very large degree in the opinions so strongly asserted by Professor Moncorvo, I am not to be taken as denying that blood changes are an essential part of the pathology of this disease; nay, I am inclined to believe that some such changes are necessary to produce the peculiar pabulum for the parasitic germs, and that it is not improbable that some such change is a frequent result of attacks of measles and scarlatina, both of which evidently produce very marked effects upon the tracheal, bronchial, and pharyngeal lining.

ON A CASE OF URTICARIAL ASTHMA.

BY T. DAVIES PRYCE, M.R.C.S., &c.,
RESIDENT SURGEON TO THE NOTTINGHAM DISPENSARY.

JAMES R——, a lad aged sixteen, was admitted an out-patient of the Nottingham Dispensary on Oct. 19th, 1885, suffering from symptoms referable to a phimosed condition of the prepuce. He was at that time a fairly well nourished boy, and had been subject to no other diseases than those incident to childhood—i.e., measles, &c. On the 28th he was operated on for phimosis. When seen on the 30th, there being a swollen condition of the penis, a linseed poultice was ordered. Shortly after the application of this poultice the patient complained of great irritation, itching, and tingling of the skin, first over the part to which the linseed had been applied, and subsequently over the whole surface of the body. This was followed by an eruption of urticaria, which, starting on the abdomen, extended to the head and neck and other parts of the body. Simultaneously with this cutaneous eruption—and even with the irritation which preceded it—the patient experienced considerable difficulty in respiration, which increased in direct proportion to the amount of the urticarial rash, developing into actual dyspnœa when the eruption attained its height. This condition continued for nearly three hours, with fairly marked intermissions both as regards the rash and the difficulty of breathing. The cessation of the dyspnœa was followed by slight expectoration. The rash and the asthma coincidently subsided. Another attack occurred at 5 P.M. on the same day, lasting three hours. On the 31st similar attacks occurred at 11 A.M. and 5 P.M. He was seen when recovering from the morning illness. An inspection of the oral and nasal mucous membrane was omitted. On Nov. 1st the same condition was present. The patient had had three attacks during the course of the twenty-four hours. On the 2nd the dyspnœa and urticaria were as before. On the 3rd he was visited at 11 A.M., and found to be covered with an urticarial rash of characteristic appearance and suffering from a typical attack of asthma. The patient had to be supported in the sitting posture, and exhibited the usual signs and symptoms of an asthmatic attack. The pulse was small, quick, and feeble, beating 120 to the minute; the temperature 100°. The mucous membrane of the nasal and oral cavities was carefully inspected, and was found to be swollen and red in places. These swellings in some parts were diffuse, in others they possessed a more or less circumscribed border. They could be seen on the posterior wall of the pharynx, and also on the soft palate. Had it been possible to use the laryngoscope, I have little doubt that they would have been discovered in the larynx. The voice was subdued and husky, the patient only being able to speak in a hoarse whisper. The patient had a similar attack during the following night. He was ordered a saline with arsenic, after which there was no recurrence of the rash and dyspnœa.

The family history was good: no account of asthma, phthisis, or neurotic tendency. I believe from the foregoing details that most observers will agree with me in terming the disease now under consideration "urticarial asthma."

This case is of interest in more than one respect. In the first place, it brings clearly to the front the fact that sometimes asthma may be caused by the presence in the mucous membrane of the respiratory tract of swellings of an urticarial nature, they bearing a strong similarity to those which simultaneously appeared on the cutaneous surface. Secondly, the fact that urticaria and asthma may occur as one and the same disease, or as one and the same external expression of a certain condition of the blood or nervous system—as evidenced by the similarity of the eruption, and by the simultaneous appearance of both these phenomena—induces the consideration of the great resemblance which exists between these two diseases. Thus, with regard to causation, asthma (peptic variety) may result from taking certain articles of food, from indigestion, &c.; so may urticaria. Mental emotion, various irritations, and uterine affections may alike cause asthma and urticaria. The periodicity of attack in asthma and urticaria is sometimes marked. Both diseases are evidently of a neurotic nature. Thirdly, cases of urticarial asthma may be looked upon as occupying an intermediary position, in reference to the seat of the disease, between hay and so-called ordinary spasmodic asthma. Thus, in the case described the disease was located not more or less exclusively in the nasal cavities and pharynx, but evidently extended some considerable distance down the bronchi, as shown by the ordinary signs of spasmodic asthma. Fourthly, with regard to the cause of the attack, the operation for phimosed prepuce or the application of adulterated or impure linseed seem to me the most probable. Looking at the above considerations, one is led to inquire whether many of the cases of so-called spasmodic asthma are not due to swellings of a more or less circumscribed character of the bronchial mucous membrane, which bear a greater or lesser resemblance to the eruption of urticaria. This view (i.e., that asthma is a neuro-vascular disease) has been strongly insisted upon by Sir Andrew Clark[1], and also to some extent by Weber. Cases such as the one above described, and the consideration of the close alliance which in many respects exists between urticaria and asthma, seem to lend support to Sir Andrew Clark's theory.

THE CASE OF EDWIN BARTLETT.

MERCURIALISM; DEATH FROM LIQUID CHLOROFORM; NECROPSY.

BY ALFRED LEACH.

THE case "Regina *v.* Bartlett and Dyson,"[2] which under the name of the "Pimlico Mystery" attracted its full share of popular attention and sensational interest, presents problems of permanent interest to medical psychologists, jurists, and practitioners. I shall endeavour to set forth the medical history of the several features of the case as fully as possible and for purposes of study, and, to the best of my ability, will let my facts stand clear of the shadow of my inferences.

[1] Opening address on Asthma at the Cambridge meeting of the British Medical Association: "Theory of Bronchial Asthma." (International Journal of the Medical Sciences, Jan. 1886.)

[2] A full report of the trial appears in the Central Criminal Court Sessions Paper, vol. cliii., part 618, pp. 725-811, published by Messrs. Barnett and Buckler, of 89, Chancery-lane, to whose courtesy I am indebted for the use of an advance proof for the purposes of this article.

Digitized by Google

About 10 A.M. on Dec. 10th, 1885, at 85, Claverton-street, S.W., I first saw Mr. E. Bartlett, aged forty. I found him reclining on a sofa. He was a rather short muscular man, in appearance not much over thirty, of fair complexion, with blue eyes and light brown beard. He was somewhat pale, and looked timid, anxious, and nervous. His limbs were a little shaky. It was difficult to "catch his eye," but it could be arrested momentarily by a direct reference to his bodily ailments. He was not much inclined to speak, and turned to his wife for answers. Was evidently suffering from a little pain; when he lay back he did so with cautious movements and an air of exhaustion, but could move sharply enough when his attention was taken off himself. Pulse small and frequent; pupils very contracted (this condition of pupil was persistent till death); skin cool; breathing and temperature normal. He complained of diarrhœa, with tenesmus, sickness, some pain in the abdomen, "bad mouth," and great sleeplessness. (*a*) Diarrhœa: The motions which his wife had preserved for my inspection were dark and loose, like chopped spinach mixed with a little tar, and were accompanied by some clots of red blood. He had no piles. The urine was very scanty, but normal. (*b*) The vomit was watery, containing bits of partly digested food and some bile. (*c*) The pain in the abdomen was not severe or localised, but the left iliac region was dull on percussion, and there was tenderness in the regions of the stomach and sigmoid flexure; the rest was tympanitic. (*d*) The breath was offensive, with the peculiar mercurial odour. The tongue was coated, especially posteriorly. He complained of a bad taste, but could not describe it. The gums were red, swollen, and spongy, with a deep bluish-red margin about an eighth of an inch in depth. In the upper jaw this edging was slight, though distinctly present; in the region of the lower bicuspids it was more developed; but in the edges of the gums of the lower canines and incisors it was very obvious. Some salivation and tenderness about the parotids existed. The teeth showed signs of neglect, but the patient did not complain of much recent increase of pain in them. The lower canines and incisors were fairly good, but had few opposing teeth in the upper jaw. There were over a dozen loose molar stumps in a horribly carious condition. (*e*) Complained of insomnia; as a rule little sleep sufficed. Asked for my diagnosis, I replied, "Mercurial poisoning." He could not account for the mercury, and said, in private, he had never had syphilis. A careful search failed to reveal any trace of the disease, and its absence was confirmed by the post-mortem and by a special search seven days after death. I suspected syphilophobia and his having resorted to quack specialists, but his assurances negatived both. Finally, he remembered taking a few days previously, and for no accountable reason, a pill of unknown quality, but no other medicine for weeks. He had been ill two or three days when I saw him, and the symptoms had steadily increased. The diarrhœa, melæna, and sickness were cured by bismuth and cinchona in a couple of days; the mouth somewhat improved under chlorate of potash lotion; and a little sleep was ultimately obtained by opiates.

But whence the mercurialism? Had the patient been practising suicidal experiments? Was he the victim of a poisoner; or were these symptoms accidental to an ordinary mercurial dose taken by a patient in bad health and highly sensitive to the drug? Tentative *felo de se* is somewhat negatived by his subsequent anxiety (apparently real) to have various things tested for mercury. He was a member of a firm of grocers, and did the wholesale buying part of the business—the tea tasting and mixing, the butter and cheese tasting, &c., as many as 300 samples in a day. It seems like straining hard for a theory if one suggest that he, a professional taster and a man who by all accounts carried tasting to the height of a fine art, was having administered to him a mercurial salt without discovering it; and advocates of this theory would have to fall back, I presume, on the tasteless but heavy subchloride for support. 1. I concluded the dose of mercury was not large because the case yielded so readily to such simple symptomatic treatment, and profuse salivation and tremors were absent. 2. But the melæna and blood suggest a large dose. The man's digestive organs were in a precarious state owing to his vocation, and he probably had an idiosyncrasy for mercury. Few drugs seemed to produce their normal results on this patient. 3. It was not chronic poisoning, because the symptoms were recent and urgent, and, again, profuse salivation was absent. 4. But the blue line is, when present, a sign of chronicity. Still, a man with a cleaner mouth—i.e., less hydrogen sulphide to seize upon the mercury circulating through the gingival margins—would probably have escaped this blue line under similar circumstances. Finally, what preparation of mercury did he take? He picked the pill to which *he* attributed these symptoms from a drawer of old samples in a grocer's shop. If this caused his symptoms, did it contain impure calomel (subchloride *plus* perchloride)? Was it corrosive sublimate pure and simple? Was it an ancient blue pill (grocer's quality) containing sulphate of mercury formed by the action of the H_2SO_4 occurring as an adulterant of the confection of roses? Was it mercury pill and nothing more? We shall never know. The symptoms were strangely suggestive of corrosive sublimate.

From Dec. 13th to the 31st, when the patient died, the case is chiefly one of psychological interest, and before approaching it in that light I will give a brief "previous history," and clear the ground of one or two physical complications. The patient is reported to have enjoyed robust health until the summer of 1885. Some years previously he suffered somewhat through overwork at amateur house-building. His teeth were always his chief trouble. About ten years ago he had the misfortune to be supplied with a gold plate without having the subjacent stumps extracted, and the plate soon became unbearable. A second set of teeth was made, and this too was discarded. Thenceforth he abjured the services of his dentist and toothbrush. Strange to say, his digestion appears to have remained perfect, though sorely taxed by irregular diet, tea-tasting, &c., until a few months before he died. He is said to have occasionally suffered, during the last year of his life, from a paroxysmal pain in the left side, a glass of wine being sufficient to provoke it There was no history of previous illness, and, medically speaking, his family history was good. Though always a shrewd man of business, he seemed to have been in private life somewhat peculiar. One fact elicited at the trial may be interesting to note: his handwriting could never be depended upon; it varied from day to day. He was not an illiterate man; he had a reverential regard for advanced learning; but his studies of late years seldom took him beyond veterinary works and books about dogs; and he had some taste for political economy. He was retiring, diffident, and in no sense unmannerly. He married when nearly thirty. His marital relations, it will be remembered, are stated to have been of a most unusual character. He was of generous instincts in pecuniary matters, sending unsolicited subscriptions to charities, and is said to have kept an earthen jar full of small silver coin for handful distribution among the poor. About December 13th he complained of increasing pain in the gums and tenderness in his teeth, and these were getting loose. By the 15th the blue line was giving way to a dirty grey one, with a red area of demarcation between it and the rest of the gum. The inner surface of the lip in contact with the stumps of the upper central incisors presented a superficial greyish and white sore as large as a sixpence. On the 16th Mr. T. A. Roberts, L.D.S.R.C.S.Eng., who coincided with the diagnosis of mercurialism, removed these two stumps; the mucous membrane of the lip healed, and the gum soon grew over the vacant sockets. The following day (17th) Mr. Roberts extracted ("picked out" would be the better word) about eleven very rotten loose stumps and teeth from the upper and lower molar regions. On the 18th all bid fair for recovery excepting the front of the lower gums. Here the whole margin of the gum had sloughed, and I removed a dead strip about an inch long and over an eighth of an inch broad, leaving exposed the edges of the alveoli and a ragged granulating gum. A long, greyish, and dark stain along that part of the mucous membrane of the lower lip hitherto in contact with this slough was observed. On the 19th Dr. Dudley described the gums as presenting a ragged edge. On the 20th the mucous membrane of the lower lip presented a longitudinal dirty slough, the four lower incisors were loose and painful, and the gum anteriorly and posteriorly exquisitely tender and receding from the bone. On the 21st the dental surgeon extracted the four lower incisors, and the inner surface of the lip improved, but the gums continued to recede from their alveoli. About the 28th the condition was as follows:—Breath offensive. Upper and lower gums healed, with the exception of the lower incisor region, where there lay a broad flat fungoid substance that seemed to spring from the empty sockets; it was supposed to consist of decomposed food, mucus, and coagulum; it extended from one to the other canine teeth, and its antero-posterior measure-

Digitized by Google

ment was about three-quarters of an inch; it could be raised from the front and back gums which bordered it but its partial removal from the alveoli caused pain. The local treatment included the application at various times of chlorate of potash, Condy's fluid, and emulsified iodoform. On the 31st the alveoli beneath the fungoid growth were blackened and very painful, and, to make things worse, the edge of the gum round the lower left canine began to recede and slough, and the patient complained of great pain in that tooth. Between this canine and the next bicuspid a space existed in which a second fungoid mass was lodged, and it was decided to extract the tooth in the hope of alleviating the pain and clearing away the accumulation. On this occasion nitrous oxide gas was given, the patient taking a very large quantity, and recovering from its effects exceptionally rapidly. He expressed himself relieved, and was in very good spirits and quite talkative, and returned home to take his supper. (That night he died.)

Another ailment presenting itself for treatment was "subacute gastritis." By this expression I mean simply a more or less acute exacerbation of a more or less persistent dyspepsia. The history given me on Dec. 10th was one of mild dyspeptic troubles during the preceding months. These troubles had increased in severity during the last week; they were temporarily overshadowed by the mercurial symptoms, and soon improved under bismuth, &c. An explanation of their occurrence is written large in the account given of the patient's habits by witnesses. For instance, while living at Dover, he would, after three or four hours' sleep, rise at 3 A.M., travel to London, work hard all day at tea, cheese, and butter tasting, or engage in the worry of his wholesale and retail business, to which he was enthusiastically devoted, make a "snack" here and a hurried "snack" there stand in lieu of meals, and then return to Dover late at night. Add to this his inability to masticate. He was strictly temperate in the matter of alcoholic drinks. His digestive organs were practically sound by the middle of December. The next event was the appearance, without any previous symptom indicative of its existence, of a lumbricoid worm on the 23rd. Suspecting the presence of more, and misled by his assurance that he felt one wriggling in his stomach, his gullet, his throat, I administered santonine on the afternoon of the 26th, and followed this up by purgatives, which utterly failed in producing an evacuation. The list of those taken between 3 P.M. and 3 A.M. is as follows: Two drachms of sulphate of soda; two drachms of liquid extract of cascara sagrada; five drachms of sulphate of magnesia; two drachms of tincture of jalap; one minim and a half of croton oil. He said he was sure I was giving him stimulants to strengthen him; he especially affected the croton oil—it was "so comforting and made him feel so strong." The majority were swallowed in my presence, for I half suspected him of duplicity when the first ones did not furnish results, and I dreaded leaving santonine in him. He took hot tea and coffee, and finally I applied galvanism to the spine and abdomen. About 3.30 A.M. he said he was "feeling a bit tired and wanted some solid food"; so, with a humiliating sense of defeat, I left, telling him that the resources of civilisation were at an end. Six hours later his usual matitudinal evacuation occurred, but on this occasion it was unusually small in amount. The amazing part of this episode is that during the preceding fortnight his bowels had been fairly regular; from the 26th mild constipation set in, and was treated with belladonna and phosphate of strychnine. But no second worm was ever discovered.

(To be concluded.)

TESTIMONIAL TO PROFESSOR BERTRAM WINDLE, M.A. The students of Queen's College, Birmingham, met on the 18th inst., under the presidency of the Warden, the Rev. W. H. Poulton, to present a testimonial to Dr. Bertram Coghill Windle, M.A., their Professor of Anatomy, on the occasion of his marriage. Mr. H. S. Chavasse read an illuminated address expressing the students' deep gratitude and best wishes for their distinguished teacher; and Mr. J. F. Jordan formally presented the testimonial, which consisted of a handsome case of plate. Professor Windle, on rising to return thanks, was received with enthusiastic applause. The proceedings concluded with a vote of thanks to the Warden, moved by Professor Bassett, and seconded by Mr. Ernest J. Gamgee.

ST. BARTHOLOMEW'S HOSPITAL.

BULLET-WOUND OF FOREHEAD; OPTIC NEURITIS; PARTIAL RECOVERY.

(Under the care of Mr. THOMAS SMITH.)

THE notes of the following case, which we are enabled to publish through the kindness of the surgical registrars of the hospitals in which he was treated, will be read with considerable interest. The bullet, which was an ordinary slug, in common use in revolvers, was fired off close to the forehead, and, taking the course described in the report of the necropsy, lodged in the posterior clinoid process, dividing the left optic nerve in its track, and compressed but did not wound the carotid artery. The symptoms appear to have been chiefly due to inflammatory changes and suppuration in the track of the bullet, and loose sequestra required removal, but there was obviously no chance of removing the foreign body. The patient lived altogether 291 days after the receipt of the injury. We recollect to have seen a somewhat similar case at St. Thomas's Hospital about eight years ago, in which the bullet passed in a similar direction and for the same distance, entering through the right upper eyelid, the infliction of the injury being followed by blindness in the left eye and ultimately atrophy of the disc. This patient, however, recovered, and is still alive. For the following notes we are indebted to Mr. A. A. Bowlby, surgical registrar.

G. M——, aged nineteen, was admitted into Henry ward, under the care of Mr. Smith, on July 10th, 1885, suffering from a bullet-wound in the forehead. The wound was said to be suicidal. The patient was in a semi-conscious state; he could tell his name, but was quite unable to give any account of himself, and did not appear to understand the questions put to him. He was very restless and noisy, constantly shouting and uttering inarticulate sounds. In the middle of the forehead was a bullet-wound communicating with a fracture of the frontal bone, and bleeding profusely. A probe could be readily passed for a distance of three inches and a half in a direction downwards, backwards, and a little to the left. There was a good deal of swelling about the left eyelid and conjunctiva, with bleeding from the nose and vomiting of blood. The pulse was 64, and a little irregular; temperature 98·4°. For the next twenty-four hours the patient continued very restless and noisy. His temperature reached 100° in the evening following the accident; he did not sleep at all. The next night he became quieter, and slept for four hours after a dose of bromide of potassium and chloral.

July 13th.—The patient at times talked quite sensibly and coherently, at other times he wandered. He said that he was blind in the left eye. Pulse 64; temperature 100°; passes urine naturally.

14th.—As the discharge did not seem to escape very readily from the wound, a drainage-tube was inserted; he is now quite sensible, and only complains of pain in the left side of the head. Pulse 60; temperature 99·8°.

16th.—As the pain continued, four leeches were put on to the left temple, to the great relief of the patient. Pulse 76; temperature 101·8°.

17th.—Patient is extremely irritable, and refuses to be examined in any way; complains of pain and is very noisy; after eight leeches had been applied to the mastoid processes he became quieter and easier.

From this time the patient gradually improved. He was never again unconscious, though at times very irritable and noisy. His temperature sank to normal on Aug. 4th, never having been higher than on July 16th. Sometimes he slept well, at other times morphia injections were necessary. An examination of the left eye showed that the disc was in a

Digitized by Google

very marked condition of white atrophy, but all the media were clear. There was absolute blindness. The discharge from the wound diminished, but did not entirely cease. No necrosed bone could be found after careful examination under chloroform towards the end of July. As his friends were anxious to take him out, they were allowed to do so on Aug. 17th.

GUY'S HOSPITAL.

BULLET-WOUND OF FOREHEAD; DIVISION OF LEFT OPTIC NERVE; OCCASIONAL EPILEPTIFORM SEIZURES; COMA; DEATH; NECROPSY.

(Under the care of Mr. BRYANT.)

For the following notes we are indebted to Mr. Targett, surgical registrar.

G. M——, aged nineteen, living at Camberwell, was admitted into No. 18, Job ward, on Aug. 17th, 1885, and died on April 17th, 1886. Five weeks ago the patient attempted to commit suicide by placing a pistol against his forehead in the middle line, about an inch above the eyebrows. On firing the pistol he felt a whirring sensation, but did not lose consciousness. He distinctly remembered being conveyed to the cab and taken to St. Bartholomew's Hospital, where he was under the care of Mr. Smith. (See *supra*.)

On admission, the patient was rather thin, and had a very heavy look about the eyes; his left pupil did not answer to the stimulation of light, and there was a slight blackening beneath the eyelashes; he was able to follow the finger when moved in different directions, both eyes working together; the left eye was not bloodshot; there was no paralysis or loss of sensation in either the limb or head, and none of the nerves to the muscles of the left eye were severed; there was tenderness between the eyes and around the wound; the bullet-wound was centrally placed between the eyes and a little above them; it was circular, and the edges presented granulations; there was some discharge from the sinus.

Aug. 21st.—Temperature 100·2°; pulse 90. The specific gravity of the urine was 1023; it contained mucus; no albumen, sugar, or blood. The patient was placed under chloroform. Mr. Bryant opened the wound between the eyes and a little above them, and took out two small fragments of bone by means of bone forceps. Retractors were placed on each side of the wound, a probe was passed, and some fragments of bone felt. The wound was dressed with iodoform gauze.

Sept. 1st.—The patient seems well, and does not complain of any pain; temperature 100·4°; he sleeps well; the left eye is still insensible to light.

2nd.—Patient has had a bad headache all night, and has had no sleep. The wound was dressed to-day, and there was a good deal of foul discharge. Temperature high and rising.

3rd.—The patient has had a bad night, and complained of severe pain in his head. Temperature 103·4°. He has been slightly delirious all day, and has taken no food; he still complains of headache, and is very restless. Pulse 150, soft and compressible; he has been sick several times, bringing up a greenish fluid. Chloroform was administered, and Mr. Clement Lucas prolonged the old incision, made another incision at right angles to the first, and reflected the four flaps; the supra-orbital artery of each side was twisted. Some granulating brain matter was then observed to be pushed up through the bullet-hole, and to be pulsating. It seemed to lie between the inner and the outer tables of the skull and in the frontal sinus. Mr. Lucas then cut with the trephine a small circular piece of bone about three-quarters of an inch in diameter, a little to the left of the median line. The granulations were then cut off, and a probe was passed; it went in easily, and evidently in the track of the bullet, for about three inches backwards and a little outwards, but the bullet was not felt, nor could any amount of pus be obtained by means of an aspirator. The probe seemed to pass under the left anterior frontal convolution.

4th.—Wound dressed. The temperature, which was 104° at midnight, this morning is 102·2°. He is restless, complains of pain in his temples, and wanders a good deal.

5th.—Temperature not so high, and he is quieter; he seems to have completely lost the sense of smell.

6th.—Wound dressed. Protruding through the trephine hole is seen a hernia cerebri, which pulsates very distinctly. The patient's condition is about the same, and his temperature varies between 101° and 103°.

7th.—The patient is lying in a semi-conscious state. He breathes rather heavily, but the pulse is moderately strong. An ice coil has been applied to his head.

During September there were frequent attacks of hæmorrhage from the trephine opening—on the 9th, 10th, 13th, 15th, 18th, and 20th. For a few days about the 9th of the month there was considerable discharge of cerebro-spinal fluid saturating the pillow, and the patient had pain at the back of the head and neck. During the earlier part of this month the temperature was usually high, and higher at night than in the morning; but towards the last week it became and continued normal, and there was corresponding improvement in the general condition.

Oct. 11th.—The patient was very drowsy, and would not take his food until late in the afternoon yesterday; he seems very sleepy again to-day, and will not speak when spoken to.

12th.—Patient has been shaking very much since last night, especially in his arms and legs. Two small pieces of necrosed bone came away from the wound yesterday, when the wound was being dressed. Wound granulating well.

14th.—The shaking which the patient had on the 12th has quite stopped; he is quiet, and takes his food well.

20th.—Patient about the same; he has a cradle over his legs, as the pressure of the clothes causes small sores to appear.

26th.—An abscess which had formed just beneath the chin on the right side was opened, and a good deal of thick greenish pus came away.

30th.—At 6.45 P.M. the patient was suddenly seized with convulsions, having been quite sensible up to the time of their occurrence; they began with contraction of the muscles of the face and clenching of the hands, and then extended to the whole of the body. The fits continued with short intervals from time to time, the length of each fit varying from one to five minutes, but the intervals rarely exceeded one minute. The convulsions consisted of muscular contractions, beginning (as a rule) in the left arm and leg, and then passing over to the right arm and leg; the pupils were widely dilated, and nystagmus was noticed in every direction; the teeth were firmly clenched, and a slightly blood-stained foam issued from beneath them. Pulse weak, varying from 130 to 140. Respiration rapid, shallow, and irregular, almost ceasing at times where the spasm was most intense. At 7.30 an injection of one-sixtieth of a grain of eserine was given, which seemed to shorten the length of the fits for a time; the dose was repeated a quarter of an hour later, but with small effect. At about 8 o'clock a quarter of a grain of morphia was given, which seemed to have very little effect. Chloroform was given for a quarter of an hour; the patient had only one slight fit during the administration, and when it was discontinued the patient fell into a sleep.

Nov. 2nd.—Patient had another fit last night, but it did not last more than a few minutes; he seems much better again this morning.

The man had convulsive seizures on Nov. 2nd, 3rd, and 6th, and the treatment was changed to twenty grains of bromide of potassium three times a day on the 7th. On the 11th he was very weak, almost collapsed, but rallied again, being able to read the newspaper on the 19th. On the 25th there was wandering and left external strabismus, with earache on the left side, which lasted three or four days. During December he improved, being able to sit up in front of the fire. The pain and deafness on the right side were complained of at the beginning of the month, and it was noted that there was much general muscular atrophy. The patient had another fit on January 6th, 1886, but during the remainder of the month he continued in fair health. The left eye was examined by Mr. Targett on the 15th; the pupil was dilated and fixed, the disc was atrophied, and there was evidence of old neuritis. During February the patient was up and about the ward every day.

March 9th.—About 7 P.M. yesterday the patient was noticed to turn very pale. At the same time he had spasmodic contraction of all the muscles of his face. His arms were also affected. This contraction of the muscles was more violent on the right side than on the left. He then became flushed, frothed at the mouth, and afterwards presented a livid appearance. In all he had some eight or nine fits. This morning on examination his tongue is found to be bitten, especially at the edge. The pupil of the

Digitized by Google

left eye is more dilated than that of the right; neither of them reacts to light. During the fits one globule of nitrite of amyl was administered. Afterwards forty grains of bromide of potassium were administered per rectum. The patient recovered again from this condition, and was about the ward until April 9th.

April 12th.—The patient took to his bed again on the 10th. He has been sick at times.

13th.—During the afternoon the patient got worse; he lies in a barely conscious condition, speaks indistinctly when spoken to, and hardly takes any notice when addressed. Does not complain of pain. Pulse 58, very weak; respiration 20, shallow. The extremities feel cold to the touch; there is no rigidity of the joints or limbs. The right pupil is rather dilated; neither of the pupils reacts to light. No anæsthesia or hyperæsthesia.

14th.—1 A.M.: The left pupil reacts to strong light; the right pupil is dilated and does not react. Optic neuritis commencing in the right eye; the disc is red and ill defined; vessels obscured by exudation; the left disc is atrophied. Knee reflexes exaggerated on both sides; ankle-clonus present; triceps reflex exaggerated; some rigidity of the left arm; trembling movements of the fingers and hands at times. Pulse 55, respiration 19. The patient is unconscious.

15th.—The patient is still unconscious; takes but little nourishment; passes everything beneath him; occasionally there is a spasmodic action with one of the hands: the hand is generally lifted up to scratch the nose; otherwise there is no movement whatever.

17th.—Patient died about midnight; his respiration stopped some ten minutes before his pulse ceased beating; artificial respiration was resorted to for some time, but with no real effect; he was still perfectly unconscious when he died. Temperature 100·4° before death.

Post-mortem report by Dr. Goodhart. — Body well nourished. In the median line of the forehead, slightly inclining to the left, was a small circular aperture with a depressed cicatrix around it; a probe passed from this into the right frontal sinus would not, from some cause, go directly backwards or into the left sinus. When the calvaria was removed, however, the right frontal sinus was not exposed, but the left was completely ploughed up and opened. The bullet track was indicated by a gaping trough full of thick muco-pus, which ran along the floor, or rather in the floor, of the anterior fossa of the skull backwards to the posterior clinoid process on this side. The frontal sinus here was opened up completely, and formed the anterior part of the trough into the ethmoidal sinus; the roof of the ethmoid having all gone, the posterior part was formed of the sphenoidal sinuses, which were in like manner opened up and full of gelatinous soapy pus. The bullet was embedded in the left posterior clinoid process and adjacent bone, and in this situation had pinned in and surrounded the internal carotid artery; but there was no clot in the vessel. It had completely severed the left optic nerve just in front of the chiasma. On turning to the brain, both frontal lobes were adherent to the dura arachnoid about the region of the wound, and there was evidence of an old meningitis of the base in various white milky thickenings. The surface of the brain was dry-looking and the convolutions flattened all over the vertex. A large abscess existed in the right frontal lobe, occupying the greater part of it; it would hold perhaps two ounces. The pus was thick, green, and free from smell. In addition to this large abscess, there was a small cyst holding about a drachm just behind and below it. This was of quite a different appearance to the other; its contents were broken-down altered grumous blood, and its wall was yellow and atheromatous-like in appearance. I thought at once that it might be aneurysmal, but it was not tough enough for an arterial sac. It was not distinct from the brain, and I could find no dilatation of vessels leading to it or any vessel at all. It was therefore a bruised patch of brain, and inasmuch as it was close to the position of the wound made by the bullet I have no doubt it was produced by the original injury. The wall of the front cyst (the abscess) was fairly tough, and a millimetre or so in thickness. Its lining membrane was very vascular in appearance. This abscess had all but opened into the ventricle, but not quite. The wall of the right ventricle was distinctly thin and the brain soft beneath the outer edge of the nuclear caudatus (head). The ependyma of both lateral ventricles was markedly sandy. The other viscera were not examined.

GREAT NORTHERN CENTRAL HOSPITAL.

FRACTURE OF THE NASAL AND SUPERIOR MAXILLARY BONES, FOLLOWED BY NECROSIS AND ABSCESS WITH PROPTOSIS; REMOVAL OF THE SEQUESTRUM; REMARKS.

(Under the care of Mr. W. Spencer Watson.)

In the following case the occurrence of a considerable proptosis, with distortion of the nose, gave rise to some obscurity in the diagnosis. The patient was first seen at a late period of the case (fifteen months after the injury), and the protrusion of the eyeball, accompanied by a nodular swelling of the lower margin of the orbit, pointed at first to some chronic form of disease involving the orbit, and possibly extending upwards from the antrum. The subsequent history of the case, however, makes it clear that the irritation set up by the presence of the sequestrum in the nostril sufficed to explain all the symptoms.

Ada H——, aged seventeen, a healthy, well-grown girl, came under observation in February, 1886, with an unsightly protrusion of the right eyeball and a swelling of the right side of the nose. Fifteen months before, one of her fellow work-girls struck the patient by a sudden movement of the head against the bridge of the nose. This was followed by much pain and swelling of the parts, and ever since there had been a constant discharge of sero-pus from the right nostril, with the accumulation of mucous crusts, which were removed with great difficulty. The protrusion of the eyeball had come on quite recently.

On admission (March 12th, 1886) there was much swelling of the whole of the right side of the nose from the region of the lacrymal sac downwards, and extending somewhat over the bridge of the nose to the left side. There was mucous regurgitation on pressure over the sac. The nostril was partially obstructed by crusts of mucus, with occasional discharge of blood-stained matter; very little fetor. At the lower border of the orbit near the inner canthus a firm nodulated button-shaped swelling was felt by the finger, with slight mobility, and free from adhesion to the skin covering it, but attached deeply to the floor of the orbit. Some redness and swelling of the lower eyelid and regurgitation of mucus from the sac took place when pressure was made over it. On probing the nostril (a view of the interior of which was obstructed inside the vestibule by considerable swelling) no bare bone could be felt. The vision of the protruded eye was not affected, nor was there any diplopia. There was no visible swelling in the roof of the mouth nor in the pharynx. Under the angles of the jaw on both sides were several enlarged lymphatic glands.

March 15th.—Bare bone was felt by the probe on the outer wall of the nostril. The right canaliculus was slit up and probed, but no bare bone was felt in that direction. A large ragged ulcer, with everted edges, was seen just within the vestibule of the right nostril, occupying its outer side and extending upwards. Bare bone was felt in this situation.

31st.—The girl was put under the influence of ether, and after full exploration a piece of necrosed bone was found lying in an abscess cavity communicating with the nostril. The finger could be passed into this cavity, and the sides were felt to be formed by fragments adherent to the soft parts. The sequestrum removed was of the size of a split pea, and had ragged edges and surfaces. Deeper in the nostril, towards the middle meatus, another bare surface of bone was felt. It was not loose, but a portion was scraped away. The cavity from which the sequestrum was removed was freely scraped and cleaned by a small gouge. The girl recovered well from the operation, and the nostril has been syringed with a solution of permanganate of potash, and boric acid ointment applied frequently.

April 19th.—The swelling of the nose has completely disappeared, the loose fragments forming the wall of the abscess cavity having fallen into their respective places. There is still an indication felt by the finger through the skin of the side of the nose of the position originally occupied by the sequestrum, but there is no visible distortion, and the nose is perfectly symmetrical. The protrusion of the eyeball is becoming less every day, and the nodular swelling on the floor of the orbit is receding. The lymphatic glands under the lower jaw have almost disappeared.

Remarks.—The irritation set up by the presence of the necrosed piece of bone in a confined abscess cavity gave rise to so much disfigurement and swelling, that the case, when

Digitized by Google

first seen, presented some of the features of a specific ulcer within the nostril. The enlarged lymphatic glands under the angles of the jaw also gave support to this view of the case. As, however, all the symptoms have subsided, it seems probable that the local irritation was due to septic poisoning from the abscess cavity, and the proptosis was probably due to a diffuse cellulitis of the orbit starting from the same focus of infection. Had the sequestrum remained, there would no doubt have been an extension of inflammation with abscess in the orbit, and possibly general septicæmia might have been set up.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Adenoma of Ovary.—Adenoma of Palate.—Neuroma of Parotid.—Actinomycosis in Man.—Erythrasma.—Vessels in Meningitis.—Gangrene of Lung.—Miliary Tubercle in Pulmonary Artery.—Mediastinal Tumour.—Peripheral Neuritis, Myelitis, Pachymeningitis.—Duct Papilloma of Breast.—Secondary Epithelioma of Jaw.—Osteochondro-sarcoma of Breast.—Osteochondroma of Thigh.

THE last meeting of the session of this Society was held on Tuesday last, Dr. Bristowe, President, in the chair.

Dr. COUPLAND (hon. secretary) read the report of the Morbid Growths Committee on Mr. Peek Richards' specimen of intracranial tumour. The tumour was a cyst with very vascular sarcomatous wall, into which hæmorrhages had occurred; it was developed from the infundibulum and third ventricle. The report was signed by Drs. Fred. Taylor and F. C. Turner.

Mr. F. S. EVE showed two Ovaries removed by Mr. Lawson Tait. In one ovary there was a circumscribed fibrous mass in one part and cysts in the other half, but they had no connexion with each other. The fibrous mass showed columns of germinating epithelium separated by a fibrous stroma. The specimens suggested one mode in which cystic disease might be produced by development from adenomatous tissue. The account of the development of the ovary given by Balfour, confirmed by Klein, showed that the germinating epithelium became thickened, and then the stroma grew into and divided it up into the trabeculæ. But in the development of the ovary an evolution of the Graafian follicles occurred, but this did not take place in the adenomata. Reference was made to a specimen of Mr. Alban Doran's, of a tumour weighing 14 lb., from a girl aged sixteen, in which similar appearances obtained, with a hyaline degeneration. Klein had described small masses of embryonic tissue in the fully developed ovary, which might form the starting-point of tumours. It was possible that cystic disease of the ovary might develop from such nests of cells. Mr. Eve thought that these observations brought ovarian tumours into the same line of formation as tumours in the breast, testicle, and skin—a generalisation of considerable importance.—Mr. ALBAN DORAN said that if Mr. Eve had confined his remarks to adenoma he should have entirely agreed with him. He was not prepared, however, to connect adenoma with cystic disease, and had examined 200 specimens without finding any evidence of such connexion. In Hart's paper on General Anatomy the extreme difference in the developing structure of the ovaries of such animals as cats, dogs, and human beings was pointed out. The embryonic tissue described by Klein had been shown to be relics of Wolffian bodies wandering in from the hilum of the ovary.

Mr. HUTCHINSON showed specimens of Adenoma of the Palate. The first was a slowly growing and slowly ulcerating tumour situated at the junction of the hard and soft palate; it occurred in a lady aged thirty, and had grown for one year, was ill defined at its edges, and ulcerated in its centre down to the bone, which could be struck; it was curious that no inflammation had occurred around it. Sir James Paget agreed that it was a most unusual form of growth. It was freely removed ten years ago, and had not recurred, neither had the glands been affected. The second case was also a quiet ulcerated tumour with bossy edges, and situate in the same place; it appeared in a gentleman aged forty-five, and also without any glandular implication. This was also freely excised six months ago. The structure of it was that of an adenoma, like the salivary glands in places and the tonsil at other parts. The ulcer had the appearance of a large open follicle of the tonsil, at the bottom of which a cheesy mass of very fetid substance existed; this ulcer did not expose the bone as in the first case, and there had been no recurrence. The literature did not throw much light on such cases, few authors mentioning the ulcerative quality of the tumours. The specimens also differed in not being encapsuled, most of the palatal adenomata being encapsulated.—Mr. BARKER referred to an adenoma of the palate that Mr. C. Heath had removed; it also presented the fetid caseous material in its base.

Mr. HUTCHINSON, jun., showed a Neuroma of the Parotid Gland, one inch in its longest diameter, taken from the left parotid by Mr. Waren Tay. It shelled out with the greatest ease, and the operation was followed by facial paralysis. The tumour was composed of minute round or oval bodies, from $\frac{1}{110}$th to $\frac{1}{210}$th of an inch in diameter, which broke up into concentric capsules, like the layers of an onion. Each had a concentric arrangement of cells and fibres, like end bulbs; there was no doubt of the existence of nerve fibres. The tumours probably developed on the branches of the facial nerve trunk. Reference was made to some observations of Rindfleisch and of Czerny on plexiform neuroma; but the specimen shown seemed to be unique.—Mr. BUTLIN said at first the specimen reminded him of a neuroma figured in Virchow's *Die Krankhaften Geschwülste*; but this was not the case. He had not been able to find either picture or description of a similar specimen, which must therefore be exceedingly rare.—Dr. HALE WHITE did not regard the concentric bodies as of so highly developed a nature as end bulbs; and end bulbs, on a motor nerve like the facial, would be very unlikely to occur.—Mr. HUTCHINSON, in reply, said that there were sensory nerves in intimate relation with the parotid gland.—The specimen was referred to the Morbid Growths Committee.

Dr. T. ACLAND read a paper on the Etiology and Pathology of Actinomycosis. Reference was made to a paper by Mr. Shattock in the Transactions of 1885. As to the clinical signs, they presented no specific characters. The actinomyces were found in the centre of each area of inflammation; in the cow they had the appearance of tufted rosettes with pyriform or clubbed-shaped rods. The first cases of human actinomycosis in this country had been recorded by Dr. Sharkey and himself; Mr. Shattock subsequently described some cases. In the human being the appearance was that of innumerable fine threads, single, branched, clubbed, or straight. He maintained and gave his reasons for believing that the structures were not due to the method of preparation, nor were they post-mortem growths, and certainly not crystallised fat due to retrograde changes in caseous products. Unsuccessful attempts had been made to cultivate the organism. Israel had attempted to inoculate a calf with the human mycotic material, but without success, though he had watched the animal for several months. One observer had cultivivated the actinomyces in gelatine and blood-serum, but he had not succeeded in reproducing the disease in animals. The structures did not become altered by acetic or nitric acids, nor by ether or alcohol, and were not blackened by osmic acid; they stained like an organism. Injection into a vein of the ear of a rabbit of cultivations of aspergillus fumigatus was followed by the death of the animal in a few days. Then spores could be found sprouting in a large vessel of the lung; this proved that mycelial growths could be causes of disease in animals. To show that the actinomyces was not an accidental contamination of a microscopic specimen, he exhibited a specimen of Dr. Percy Kidd's, which showed how unlike the two things were. Again, Mr. Solly had shown a preparation of crystallised fat from caseous material which did not stain; this to meet the other objection that the actinomyces was a crystalline product.—Dr. BRISTOWE believed that similar appearances were to be seen in the Madura foot, though the masses of growth were larger and coarser in structure.—Mr. CROOKSHANK showed many specimens of micro-organisms; actinomyces showed a likeness to the threads of mucor. In some kidneys a kind of mycosis produced by spores of fungi—aspergillus fumigatus—had some resemblances also. He agreed that it was difficult to demonstrate the club-shaped rods in some of the specimens. Jöhne had described a mycotic disease having clinical features like those of actinomycosis. In some of the preparations made by Mr.

Digitized by Google

Crookshank it was easy to demonstrate the radiate structure in the fresh state, but not in stained specimens.—Dr. PERCY KIDD considered that one of the merits of Dr. Acland's work was that he had succeeded in proving that we had to deal with two sets of cases, that of actinomycosis bovis and the human variety. In the latter an appearance of a number of threads as of bacillus was bounded by small colonies of bacilli at their periphery.—Dr. ACLAND, in reply, thought the question of the organism in Madura foot would repay reopening, especially after the investigations of Lewis and Cunningham; he did not think the organism was the same in Madura foot as in actinomyces, but even in the latter he was not prepared to say what the growth was, whether aspergillus, mucor, or bacillus—nor, indeed, whether it was communicable from animals to man.

Dr. F. PAYNE showed a specimen of Erythrasma taken from a man aged forty, who for ten years had had a brown patch on the scrotum and corresponding part of the thigh; it was scaly and of a coffee-ground colour, not unlike pityriasis versicolor. After staining with methyl violet an organism of minute dimensions showing filaments one-third the size of the trichophyton was visible. Burchardt and Baerensprung had described a similar organism under the name of microsporon minutissimum, a minute fungus. Again, Bizzozero of Milan averred that these were bacteria, and occurred in the skin of man as a leptothrix development of bacillus. The point was whether they were the cause of the skin affection. The organism had been described as existing in the moist part of the groin and between the toes, and also in parts kept moist by inflammation. Dr. Payne had not seen the same form of organism before, and it was difficult to believe that it had not the same apparent causative relation to the disease as the organism found in chloasma.—Dr. T. C. FOX showed similar specimens from the thigh of a man suffering from diabetes; they existed in great abundance as long threads ramifying after the same plan as trichophyton; plain tubes and tubes with compartments and moniliform shapes were to be seen.

Dr. HANDFIELD JONES showed numerous drawings of Vessels from cases of Meningitis. He wished to demonstrate the origin of the corpuscles in the rete of the pia mater, and also certain changes occurring in the minute vessels. Dr. Bastian had described the migratory property of the cells eight years ago, and attributed it to amœboid contractions. These changes were not constantly met with. Some of the corpuscles were elongated and notched, and differed from the round or oval ones in a marked manner. The alteration in structure of the vessels and the corpuscular hyperplasia, which was an active process, were probably due much more to a disorder of the vessels than to damage of the tissues themselves. There was a degradation of a specialised tissue; in some of the specimens the piamatral capillaries ended in short tufts suggestive of renal glomeruli.

Dr. SILCOCK showed a specimen of Necrosis of the Lung due to Thrombosis of the Pulmonary Artery; it occupied the greater part of the middle lobe of the right lung, and came from a woman aged forty-four, who had Bright's disease with hypertrophied heart. As there was no sign of previous pneumonia, it was thought that embolism followed by thrombosis of the branch of the pulmonary artery was the cause of the necrosis, and not a consequence of it.

Dr. F. C. TURNER exhibited specimens of Tubercles in the Pulmonary Artery taken from a boy aged fourteen, who had tuberculosis of general distribution. In the main branches of the pulmonary artery clusters of miliary tubercles were to be seen in the endarterium. Weigert had described these miliary tubercles in the veins in nine cases out of ten of tuberculosis, but they had not been observed, so far as he knew, in the larger branches of the pulmonary artery.

Dr. S. WEST showed several Mediastinal Tumours. In one instance the man died suddenly, and the pneumogastric nerve was found to be greatly thickened; the nerve itself was not much altered, but a large mass of small cells grew between its fibres; it was a medullary carcinoma. In a second case hemiplegia of embolic origin coexisted; the mediastinal growth was not detected during life, but the vessels were invaded by the tumour, which had spread through their walls; possibly this was the source of embolism. In another specimen the innominate vein was occupied by a large growth. He had observed in this case many small venous thromboses in the legs, arms, and trunk, the cutaneous veins being affected. There was no proof of any direct connexion between the thromboses and the tumour. In the case of a butcher who was gouty a similar kind of thromboses was found in the skin. The tumours illustrated some of the more unusual causes of death.

Dr. HALE WHITE showed specimens of Peripheral Neuritis and Syphilitic Pachymeningitis, taken from a woman aged fifty-two, who had been a hard drinker and had had delirium tremens. For some months past she had had occasional right-sided attacks of convulsions. On admission she seemed partially demented, and would not answer when spoken to. The optic discs were healthy, and there was no facial paralysis. There were wasting, rigidity, and contracture of the right arm, and in a slight degree of the leg. The liver was enlarged and rough. After she had been in hospital a few days she was attacked, in the course of seven hours, with sixty-three right-sided epileptiform seizures, in which the face was affected, and which were accompanied by unconsciousness. The temperature ran up to 103°; the patient lapsed into a quiet unconscious condition, and died about eighteen hours after the last fit. At the post-mortem examination there was syphilitic ostitis of the back part of the frontal bone, causing the membrane underneath to be adherent, and under this ostitis, and over the whole of the outer surface of the left frontal lobe for an area bounded below by a horizontal line at the upper border of the first frontal convolution the membranes were quite thick and dense, being of a yellowish gummatous colour in parts and adherent to the brain, except where separated by thick yellow pus, of which there were several patches. The brain substance underneath was hardly affected. The same condition, but to a less degree, was present on the inner surface on that part of the marginal convolution immediately over the genu of the corpus callosum, causing the marginal convolutions to be adherent. With the exception of cirrhosis of the liver, the rest of the body appeared healthy. Microscopical examination showed that the pachymeningitis was characteristically syphilitic, being composed partly of fibrous tissue and partly of gumma, consisting of degenerate cells in a delicate meshwork; the nerve cells in the convolutions underneath were not at all affected. Examination of the skin from the finger showed that the fibrous sheath around the nerve formation was considerably thickened and sent in thick septa between the individual nerve fibres. These were much degenerated; in many of them no axis cylinder could be seen, and all that could be observed was the granular material into which the white substance of Schwann had become converted. Under very high powers sometimes the axis cylinder could be seen among all this granular material, itself so much distorted and degenerate that it could only be with difficulty distinguished from its surroundings. In the same section there were many affected and many healthy fibres; the change was always very chronic, there being no small-celled nor vascular increase. The median nerve appeared healthy to the microscope. The columns of Goll and central parts of the lateral columns in the spinal cord stained rather deeper than the rest of the cord, and there seemed to be a slight increase of neuroglia. This case presented many points of interest—(1) a syphilitic pachymeningitis following syphilitic ostitis was a rare though recognised sequence; (2) the right-sided Jacksonian epilepsy following the left-sided lesion was very interesting; (3) the peripheral neuritis, in view of the recent discoveries chiefly of the French workers, was important as showing that the usually received notions concerning it were correct. With respect to its etiology, it was probably due to the alcohol, but possibly to the syphilis; and, lastly, the slight change in the cord, also probably alcoholic, was to be noted.—Dr. HADDEN thought there was unquestionably neuritis, most probably due to alcohol.—Dr. WHITE said there were no symptoms referable to the part from which the nerve was removed.

Mr. BILTON POLLARD showed two specimens of Duct Papilloma of the Breast. The first specimen had been sent to him by Mr. Farnell of Eastbourne. The patient, from whom it was taken was fifty years of age. Twelve years before the removal of the breast, when six months advanced in pregnancy with her last child, the patient noticed a slight discharge of blood from her left nipple; three years later a warty growth projected from her nipple. This growth was repeatedly removed without permanent benefit, and two years and a half ago, when Mr. Farnell first saw the case, there was a growth in the breast beneath and around the nipple. The lymphatic glands were unaffected. In Oct. 1885 the breast was removed. On section the growth was invested with a distinct fibrous capsule, except at the

Digitized by Google

place where it was sprouting on the surface. The growth was composed of two portions, of which one was very friable and the other was dense and firm. The structure of the friable portion was that of an arborescent papilloma; there was a very delicate stem of fibrous tissue with innumerable offshoots, all lined with columnar epithelium; in some places adjacent papillary processes were seen bending towards one another as though about to coalesce at their extremities; in others the appearances indicated that a junction had been effected; and in others, again, secondary villi were visible sprouting into the included spaces. The dense portion of the growth was encapsuled just like an adenoma of the breast; its microscopical structure was that of an adeno-fibroma, but in the general arrangement of its tissues it bore a striking resemblance to the friable portion of the growth. Mr. Pollard suggested that the adenomatous portion was but an advanced stage of development of the papillary portion resulting from the union of its adjacent villous processes and an increase in the fibrous groundwork of the growth. He also thought that such a method of development would explain the absence of excretory ducts in adenomata of the breast. He was indebted for the second specimen to Mr. Godlee. In it the tendencies of the growth were rather towards malignancy, although there were no evidences of malignant action in the patient. The growth, which closely resembled the first specimen in its structure, was in many places invading the surrounding fat. Mr. Godlee had shown to the Society a similar case in which the axillary glands had been secondarily affected, and Cornil and Ranvier described a similar growth under the title of villous carcinoma. Mr. Pollard thought the specimens of interest as suggesting that papillomatous growth within the mammary ducts might under certain conditions develop into simple tumours—adeno-fibromata,—and under other conditions develop into true duct cancers.—Mr. SHATTOCK said that he had seen two specimens of cysts of the breast with papillary growths identical in microscopical appearances with the specimens exhibited.

Mr. BILTON POLLARD showed for Mr. Christopher Heath a specimen of Secondary Epithelioma of the Lower Jaw, removed by Mr. Heath at University Hospital from a man aged fifty-five. The primary growth was first noticed in the lower lip two years and a half ago, and was excised two years ago. A year ago the secondary growth began to form, and on admission there was a swelling surrounding the body of the lower jaw and involving the tissues in the left submaxillary space. The tissues removed consisted of the left half of the body of the lower jaw, together with the angle and a small portion of the ramus, considerable portions of the masseter, internal pterygoid and mylo-hyoid muscle, and the left submaxillary gland. The jaw was only superficially diseased by extension of the growth to it. The patient's recovery was rapid and complete. The growth was a squamous epithelioma, and the only unusual feature of it was that, though it must have primarily formed in the lymphatic glands, it had so encroached upon the jaw as to simulate a primary growth in that bone.

Mr. W. H. BATTLE showed a specimen of Osteochondro-sarcoma of Breast. The patient, who was a widow aged seventy-three, and had had five children, was admitted into St. Thomas's Hospital, under the care of Mr. Mackellar, on Aug. 28th, 1885; amputation of the breast was performed three days after admission, and she left the hospital at the end of a month. The tumour began as a lump on the inner side of the nipple six years ago; it remained stationary, of the size of a pea, for two years, and the ensuing three years it increased to the size of a hazel-nut, and then grew more rapidly; it was painless, the size of an orange, of hard consistence, and composed of two portions—an inner, very hard and rounded, about the size of a walnut, which the patient had noticed for a long time; and an outer, more elastic, the size of a large egg, a more recent development. The nipple was much retracted. The skin over it was movable, except at the inner part, where it was adherent, red, and tense. A small freely movable gland was detected in the axilla. The softer part of the growth was friable and extremely vascular, with numerous hæmorrhages; the smaller portion was very hard and resembled bone. Microscopically, the softer parts were composed of round and spindle cells; the harder, of cartilage, which in places had ossified with the development of Haversian systems. The specimen was rare.

Mr. W. H. BATTLE also showed a specimen of Osteochondroma of the Thigh. The patient, aged twenty-five, stated that he had been kicked by a horse in the left groin. A fortnight later he noticed a lump the size of a walnut in this situation. When he came under treatment three months and a half after the accident, this tumour was of stony hardness and had a slightly irregular surface; it was situated in the diverging angle between the sartorius and the tensor vaginæ femoris, and apparently under the deep fascia; it was movable laterally, and measured three inches from side to side and four inches in its long axis. At the operation it was found lodged in a bed of areolar tissue without any definite connexions. Its structure was so hard as to require a saw to divide it. The hardness of the surface was unequal; this depended on the distribution of the cartilaginous, bony, and calcareous elements of which the growth was composed. The bony part occupied the centre chiefly, but was also scattered in other parts. In certain situations, generally where the cartilage and bone passed into one another, were patches of white calcareous deposit.—Mr. BUTLIN referred to a similar case occurring in the thigh which had been under the care of the late Mr. Callender; the growth recurred two or three times at intervals of about a year. It was a spindle-celled variety, and ossified in all parts except the centre.—Mr. BOWLBY spoke of his own specimen of tumour of the breast which had undergone partial calcification; also of that of Mr. Wood, and of that of Sir Astley Cooper, which was said to consist entirely of bone.

The following card specimens were shown:—Mr. L. Hudson for Mr. E. Crookshank: Photographs of Micro-organisms. Dr. Colcott Fox: Erythrasma. Dr. P. Kidd: Aspergillus Mycosis of Kidney. Dr. Silcock: Fibroid Thickening of Pleura (? Syphilitic). Dr. Sharkey: Perforation of Vermiform Appendix. Dr. Hadden: (1) Tubercular Mass in Supra-renal Capsule; (2) For Mr. Paul, Rupture of Aorta by Muscular Strain. Mr. Battle: Bones from a case of Congenital Syphilis. Mr. E. H. Fenwick: Calculus Extracted per anum. Mr. Churchill: Central Necrosis of Great Trochanter, with Rarefying Osteitis of Hip-joint. Dr. Hale White: A series of specimens of Leprosy for Dr. Rake of Trinidad. Mr. S. Paget: General Symmetrical Psoriasis (living specimen).

CLINICAL SOCIETY OF LONDON.

Aneurysm of Aorta and Galvano-puncture.—Rupture of Aortic Aneurysm into Posterior Mediastinum and Abdominal Cavity, with Remarkable Symptoms.—Impaction of Stone in one Ureter, with Atrophy of the other Kidney.

AN ordinary meeting of this Society was held on the 14th inst., Mr. Thomas Bryant, F.R.C.S., President, in the chair.

Dr. CHURTON (Leeds) read notes of the following case of Aneurysm of the Thoracic Aorta treated by Galvano-puncture. A strongly-built man, aged forty-five, had in 1880 an aneurysm which protruded through the left chest wall. He was then in the Leeds Infirmary, under the care of Dr. Clifford Allbutt, and was treated by iodide of potassium (afterwards continued for three years), and by galvano-puncture upon two occasions. After each puncture pulsation ceased for two or three days, but finally remained as before. The aneurysm, however, did not increase in size until last year. In June, 1885, he was admitted under the care of Dr. Churton, a second tumour having appeared in front of the lower part of the sternum. This grew rapidly. With the concurrence of Dr. Allbutt (now consulting physician to the hospital), Mr. Teale, who had operated upon the patient previously, applied the galvanic needles, fifteen cells of Leclanché's battery being used for twenty minutes. Blood-débris ran from the negative puncture. The pulsation ceased, but returned on the fourth day. The operation was repeated on October 2nd with like result. He began about this time to expectorate two or three drachms of blood-stained mucus daily. On October 27th galvano-puncture was used for the third time. The tumour was tympanitic for a few hours, but did not cease to pulsate. On Nov. 9th it was so much increased in size and its walls were so thin that a fourth puncture was made, Dr. Griffith, the resident medical officer, operating in the absence of Mr. Teale. The current was passed for twenty minutes. Pulsation entirely ceased, and the patient seemed to have gained a respite, but suddenly died twenty minutes after

Digitized by Google

the operation from rupture into a bronchus of the first aneurysm, which had hitherto given no new sign except the very small quantity of bloody sputum. At the necropsy, an erosion, half an inch in diameter, almost blocked up by a clot to be described below, was found in the upper part of this sac. Except in the arch the aorta was only moderately atheromatous. One testis had undergone fibrosis. The orifice of the first aneurysm was about an inch in diameter; the wall of the sac was as firm as cartilage. The middle of the sac was occupied by a firm clot larger than a cricket-ball; the lower part of the sac was lined by laminated clot, thin around the orifice, gradually becoming thicker above, and quite smooth. The upper aspect of the central clot was rough. A fissure between the wall and the clot connected the two chambers into which the primary sac had been divided by the formation and subsequent partial separation of the clot. It seemed to the author that after the deposition of clot upon the entire sac, with closure of the upper part by formation of a very thick layer, this had been stripped from the roof of the sac by the blood, which found a way through the fissure, and then, enlarging this part of the sac, formed a projection on the exterior of the chest. A constriction in the sac, marking the position of the large mass of clot, suggested this view. The growth of this sac was arrested by the firmness of its wall except at two points both in the upper division or chamber. At one of these points the rupture into the bronchus had occurred. At the other, an orifice, one third of an inch in diameter, which existed at the lower part of the chamber, led to the second sac, which, as well as a third and very small sac, were altogether outside the chest wall. The third sac appeared to have originated by an orifice in the small piece of the wall of the primary sac, which had yielded and had become the upper limit of a short canal leading into the second sac. [The specimen and drawings were shown.] The walls of the second sac were soft, and its interior irregular, except where the sternum, quite uninjured, formed its limit. The front wall was composed merely of skin, and irregular bands or trabeculæ of connective tissue of varying thickness, disposed like the carneæ columnæ of a right ventricle. This was the cavity, as large as an orange, in which the galvanic needles had been inserted. It contained no laminated clot; the surface was smooth and uninflamed. A soft jelly of pinkish colour, too fragile to be preserved, and some blood débris were contained in the cavity. The cessation of pulsation had been due to entanglement of this clot in the short narrow canal leading from the orifice into the cavity. The temporary cessation of pulsation noted in the large aneurysm five years ago was probably due to a similar entanglement of soft clot in the narrow fissure above mentioned. The formation of such a clot and of blood débris in the cavity of a perfectly open aneurysm one would suppose to be not free from danger.—Dr. GIBBONS had the opportunity of seeing the post-mortem examination in two cases of aneurysm treated by galvano-puncture. The first was a woman suffering from aneurysm threatening to rupture externally, which was galvano-punctured successfully. Later, she died, and a firm clot was found at the point of previous puncture. The second case was that of a man suffering from thoracic aneurysm, which also threatened to rupture externally. This was punctured with needles attached to a battery of six Smee's, the operation lasting fifteen minutes. Nine days after, a second puncture was tried for one hour, and a firm clot was formed. After a time, all benefit of former operations having disappeared, puncture was a third time performed; solidification ensued, and the man resumed work. Six weeks later he returned to hospital; sloughing of skin appeared; puncture was again performed, but the edges of the wound becoming unhealthy, death occurred, apparently from pyæmia. The aneurysm was found post mortem to be of the thyroid axis. He believed there was a future in store for electrolysis, especially in gynæcology.—Dr. CHURTON, in replying, said that while disclaiming any right to speak positively, he thought that the clots which were found in the cases mentioned by Dr. Gibbons, being closely adherent to the wall of the sac, must have been deposited slowly upon the lining membrane, and could not have been formed around the needles introduced into the sac, which would, he supposed, be insulated, except at their points.

Dr. PERCY KIDD read a case of Aneurysm of the Aorta, with Extravasation of Blood into the Posterior Mediastinum compressing the Œsophagus and Vagus Nerves, and Rupture into the Abdominal Cavity, associated during life with frequent Vomiting. A labourer, aged thirty-one, was admitted into hospital on Dec. 4th, 1885, in a very exhausted state. He stated that he had been ailing for six weeks and had suffered from a slight cough, but was able to do his work until four days previously, when he took to bed on account of vomiting, shortness of breath on exertion, headache, and a feeling of malaise. He continued to vomit frequently, the headache and shortness of breath persisted, and his bowels were constipated. His previous health had been very good, with the exception that some years back he had contracted syphilis, and six years ago he had "pleurisy." On admission the patient was muscular and well-nourished, but extremely anæmic. On the lower part of one leg there was some partially healed ulceration and pigmentation. His pupils were slightly unequal, the right being larger than the left. Pulse small and weak, but equal in the two radials. Chest: Slight scattered rhonchus and slight dulness at both bases posteriorly; breath sounds rather weaker in the left than right interscapular region; over the manubrium sterni there was weak tubular breathing, but no dulness; heart sounds healthy. Abdomen soft and natural; no spots. Ophthalmoscopic appearances normal. Urine healthy. Temperature 99·0°. The next day there was no noteworthy change except that the pupils became equal; He continued to suffer from vomiting and retching, had a troublesome cough, and the temperature became subnormal. Early on the 7th he became very restless, the pallor increased, and he sank in two hours. At the necropsy the peritoneal cavity was filled with blood, but no source for the hæmorrhage was found in the abdomen. There was a small sacculated aneurysm springing from the third part of the arch of the aorta, which had ruptured into the posterior mediastinum and subpleural tissue on the left side. The effused blood was shut off from the pleural cavity by adhesions, and had burrowed down along the œsophagus, compressing it and the vagus nerves, and had entered the abdominal cavity behind the crura of the diaphragm. The aorta was atheromatous in the arch, but elsewhere was healthy. The heart was slightly hypertrophied, the lungs œdematous, and one testicle was fibroid. The other viscera were healthy. The vomiting was considered to have been due to irritation of the vagus fibres lying along the œsophagus by the pressure of the effused blood.—Mr. HARRISON CRIPPS related two cases of intra-peritoneal hæmorrhage in which uncontrollable vomiting was a marked symptom. A man jumped down from a high dogcart, and soon suffered from severe pain with vomiting every half-hour; he was somewhat collapsed, and there was slight distension of the abdomen. At a consultation internal strangulation was considered to be the lesion, and abdominal section was performed. Much fluid, dark-coloured blood was all that was discovered, but the source of hæmorrhage could not be found. At the necropsy a laceration of the posterior surface of the liver was the only lesion detected. A week or two after this case, a boy who had been run over was brought in, with severe vomiting and considerably collapsed. After death, which took place in two days, hæmorrhage into the peritoneum was found, with laceration of the spleen.—Dr. D. DREWITT remarked that in purulent peritonitis vomiting was very severe.—Dr. W. HADDEN asked if the gullet were much narrowed, and whether the vomiting was from the stomach.—Dr. KIDD, in reply, considered that there was genuine vomiting, which, he believed, was due to pressure on the vagus nerves, though some might have been due to intra-peritoneal hæmorrhage.

Mr. PICK read a case of Impaction of Stone in one Ureter, with Atrophy of the Kidney on the other side. The patient, aged forty-five, was first seen on Feb. 1st, 1884, when he was found to be suffering from almost complete suppression of urine. He had been the subject of dyspepsia, with high-coloured lithatic urine, all his life. Fifteen years ago he passed a small calculus. In August, 1883, he was attacked with severe pain in the hypogastric region, accompanied by inability to pass urine. A catheter was introduced, but no urine was drawn off. The pain, which was of a very intense character, and was accompanied by sickness and vomiting, suddenly ceased, and shortly afterwards he passed a small calculus by the urethra. Two days before he was seen by Mr. Pick he was again seized with intense pain in the region of the bladder, extending upwards in the course of the left ureter and downwards to the testicle on the same side. The pain was accompanied by a feeling of sickness, but no actual vomiting took place. It lasted for about four hours and then

Digitized by Google

passed off. Since that time until he was seen (a period of over forty-eight hours) he had only passed five ounces of urine. Upon examination he was found to be in no pain, but nervous and anxious about himself. He was sweating profusely. There was no water in the bladder. The urine which he had passed was light-coloured, almost like water, of sp. gr. 1006, and contained no albumen or abnormal deposit. The diagnosis arrived at was that the case was one of impaction of a calculus in the ureter of a patient who had only one kidney, or who had already from some cause had the other kidney permanently destroyed. The patient was ordered to drink half a gallon of distilled water daily, in the hope that this would act as a non-stimulating diuretic and cause the secretion of a large quantity of urine, which would mechanically wash the stone into the bladder. Two days afterwards his condition was manifestly altered for the worse, though it appeared to be due more to nervous anxiety than to anything else. His principal complaint was inability to micturate; he, however, also complained of a considerable amount of pain in the left side of the abdomen, and here there was to be felt a firm, hard, and resisting circumscribed swelling, which was dull on percussion. He remained much in the same state, gradually, however, getting more restless and complaining, but without presenting any fresh symptoms, until the seventh day of his attack, when he was suddenly seized with an intense desire to micturate, and in the course of a very short time passed no less a quantity than seven pints and a half of urine, and with it the passage of three small calculi. From this time his symptoms were at once relieved. His urine, which he passed in natural quantities, contained a little blood, but this soon disappeared, and in a week or two he was, as he expressed it, "quite himself again." He continued well for about a year, until February, 1885, when he had a severe attack of lumbar pain followed by the appearance of blood in the urine, and some time afterwards passed a small calculus by the urethra. On August 3rd of the same year he had a third attack of renal colic, which lasted five or six hours and then ceased, but was followed by the appearance of blood in the urine. On the 11th he had an attack of retention from the impaction of a calculus in the urethra. This was relieved by the passage of a catheter, during which the stone was pushed back into the bladder. This was followed by vomiting, hiccough, and almost complete suppression of urine. He became comatose, and died on Aug. 17th. Permission could only be obtained to examine the urinary organs. The right kidney was found to be atrophied, very granular on its surface, and with only a trace of secreting structure remaining. The left kidney was twice its natural size, its cut surface of a deep-red colour, and much congested. It contained about six or seven small calculi studded throughout its substance, and one large calculus was contained in the pelvis and blocked up the ureter. The ureter itself was natural. The bladder contained a small stone. In reply to the President, Mr. Pick said that the lumbar swelling was difficult to map out accurately, but it seemed about four inches in length, and was considered to be a dilated ureter.—Mr. GODLEE raised the question whether urine might not be rapidly secreted after the removal of an obstruction due to a stone.—Mr. BRYANT inquired as to the state of the right kidney. The treatment by large quantities of fluid could only have been effective under the peculiar circumstances of the case. In his opinion the stone must have been impacted in the upper part of the ureter, which was probably not capable of much rapid dilatation. But it could become dilated as the result of a chronic process, after which he did not think the dilatation could pass away. He related a case of calculus in the bladder in which the child was sent away from the operating theatre because the stone could not then be detected. In the course of the night the child became pale and cold, in a collapsed condition, and died. At the necropsy it was found to have but one kidney, and hæmorrhage had taken place into the pelvis of the kidney. The anæsthetic was assigned as the cause of this hæmorrhage, but death would probably have been attributed to the operation if it had been done.—Mr. A. E. BARKER believed that where we had to do with a large accumulation of urine, a urinary fistula purposely made in the loin would frequently forestall very serious consequences. The risk of the operation would be very small, as also its consequences. In a case in which he had performed this operation the woman was now, and had been for a year past, wearing a urinal; she had no further pain, and was able to follow her avocations. He considered that there were occasions on which this plan might be resorted to with great advantage.—Mr. R. W. PARKER related the case of a boy aged twelve, who was first seen in February, with a history of having fallen over a bench, and having been thereby struck in the lumbar region. He was brought to him because of the passage of very dark blood-stained urine. Under rest the pain and hæmaturia disappeared in a week, and he was not seen till one week ago, when he was again passing blood. There was a large swelling in the lumbar region, which Mr. Parker punctured, and drew off much urine, but no blood. This appeared, therefore, to be a hydro-nephrotic sac, and a free incision was made into it two days later, eighty ounces escaping. The next day no urine escaped from the fistula, and the patient was passing very little urine at all. Complete suppression set in, and within a day or two uræmic convulsions and coma, ending fatally. The right kidney was found in a sacculated condition with calculi, and the ureter was blocked up; the left kidney was a mere sac, and contained many small calculi in its loculi.—Mr. PICK said the right kidney was an example of a congenital deficiency of development; it was but one inch long, like a specimen he had shown years ago at the Pathological Society, which had the size and shape of the supra-renal capsule, with a small renal artery. The treatment in this case was only applicable to very rare cases where but one kidney was functional. The stone, he believed, had lodged at the opening of the ureter into the bladder. As to the ureter, he did not perceive why it should not contract during a period of eighteen months. If a fistula had been made in the loin, it might have done considerable harm. In regard to Mr. Godlee's remarks, he believed that the large quantity of urine was passed before, and not after, the stone had come from the bladder.

The following living specimens were exhibited:—Mr. Pearce Gould: Raynaud's Disease, affecting chiefly the left hand and foot. Dr. Henry White: Cervical Rib.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society took place on April 7th, Dr. J. Holmes Joy, President, in the chair.

Loss of Conjugate Movements of the Eyeballs downwards, and of Convergence and Accommodation.—Dr. SUCKLING showed a woman aged thirty-eight, who presented these symptoms. She had suffered from vertigo for twelve months. There was no history of syphilis. The pupils responded normally, and the fundus was normal. There was a slight general increase of the deep reflexes, most marked on the left side. In walking the body was held stiffly, and she frequently fell, falling to the left. There was no psychical change. Dr. Suckling thought that the paralysis was due to degenerative changes in the cerebellum.

Paraplegia and Anæsthesia of Legs.—Dr. SUCKLING showed a woman who had been sent to him suffering from paraplegia anæsthesia of the legs, following a fall five months previously. She was of the neurotic type; cheerful, intelligent, energetic, industrious, and eager to get well. After being informed that the application of electricity would cure her, faradisation was employed, resulting in recovery.

Dr. SUCKLING also read a paper upon Paralysis depending upon Idea and Faith-healing.

Glioma of Retina.—Mr. EALES showed an eyeball excised for glioma of the retina in a child aged two years and a half. The vitreous and retina were replaced by the growth, which, however, had not perforated the ocular tunics anywhere; the lens was transparent, and the iris not apparently involved. Microscopical sections of the tumour were typical of glioma; but sections of the optic nerve showed it to be free from infiltration by the growth, and apparently quite normal in condition.

Senile Cataract.—Mr. EALES also read a paper on some points connected with the Extraction of Senile Cataract, in which he insisted on the importance of ophthalmoscopic examination in the early stages of cataract, when only the state of the fundus can be ascertained. Bright's disease and diabetes were perhaps the most unfavourable of all the various conditions of ill-health which tended to bad results of operation. Cocaine locally applied had rendered general anæsthesia unnecessary for extraction of cataract, thus removing one source of danger both to the patient and the integrity of the eye. When all the conditions were favourable, he thought the cornual section of Liebreich with a

Digitized by Google

small iridectomy just involving the pupillary margin of the iris was a good operation and gave excellent results. The section was most favourable for removing cortical matter without the use of force, and was well placed for early subsequent inspection, while the cicatrix was hardly noticeable afterwards and the iridectomy too small to be attended with any bad results as regards vision or appearances; nor was it extensive enough to cause pain during its performance, no dragging of the iris taking place, comparing favourably in this respect with the pain caused in excising the iris down to its root necessary in all the modifications of Graefe's linear section, in which, consequently, the final stages of the operation were often attended with much embarrassment to the operator by the patients having lost their composure. When the conditions were not favourable he preferred the three-millimetre flap modification of of Graefe's operation, in which case he often performed the iridectomy previously, as in cases where glaucoma was present or its tendency suspected, or the iris non-dilatable or vascular, or Bright's disease present. He had found Forster's method of maturing the lens a most valuable method of dealing with cases of very slowly maturing nuclear cataract, affecting both eyes equally, and a means of saving months of waiting and forced idleness to the patient.

Notices of Books.

Kystes: Tumeurs Perlées et Tumeurs Dermoïdes de l'Iris. Par E. MASSE. Paris. 1885.—The explanation of the formation of cysts in or on the iris has always been felt to be a difficult chapter in ophthalmology. The first case recorded appears to have been by Mackenzie in 1832. Dr. Guépin, Mr. Hulke, Rothmund, Wecker, Monoyer, and others followed with detailed reports of cases. The great frequency with which the formation of cysts of the iris was preceded by injuries to the eye was clearly established from these memoirs; and the last-named two authors drew a distinction between liquid and solid and pearly tumours of the iris. Bowman, with Mackenzie, thought that these tumours formed in consequence of the secretion of a fluid between the iris and the posterior layer of epithelium, so that the epithelial cells of the uvea formed their posterior wall. Rokitansky believed that they proceeded from the proliferation of the connective tissue in the fibrous stroma of the iris. Wecker thought that the mode of formation of these tumours was that in the cysts a fold of the iris was made by the injury, and that an anterior or posterior synechia resulted, forming a cavity enclosing a little fluid; whilst in many instances of the pearly tumour a cilium became implanted on the iris. M. Masse admits three varieties of tumours, cysts, pearly tumours, and dermoid tumours, and has collected a large number of cases of each. He has made many experiments to determine the mode of origin of cysts of the iris. He transplanted portions of skin into the anterior chambers of the eye in rabbits, and found that they readily became attached to the iris; and whilst part underwent resorption, another part grew and formed the commencement of a pearly tumour, which, however, remained always of small size. Portions of cornea thus transplanted also grew, and formed translucent tumours. The experiments of M. Masse seem to establish in the most satisfactory manner that a large proportion of cysts of the iris, if not all, are the result of the transplantation of normal tissue by some accidental traumatism. In regard to treatment, he recommends waiting till the patient experiences some trouble in the affected eye. It should then be completely extirpated by incision through the cornea and iridectomy. M. Masse has added to the value of his paper by an excellent bibliography, and he gives two plates showing well-marked varieties of the disease.

A Text-book of Inorganic Chemistry. By Professor VICTOR VON RICHTER, University of Breslau. Authorised Translation by EDGAR F. SMITH, Professor of Chemistry in Wittenberg College, Springfield, Ohio. Second American from the Fourth German Edition. London: Kimpton. 1886.—There are many merits in Professor von Richter's little text-book, and it is not wonderful that the English version has so soon reached a second edition. The author has brought the scientific record well up to date, and has rewritten many parts. Thus, we have a sufficient account of the liquid forms of the gases formerly called permanent, such as hydrogen and oxygen, and a clear statement of the periodic law, in which, however, we are sorry to notice that the name of Newlands, the real discoverer, is omitted. The section on Crystallography is one of the best in the book.

Hospital Sisters and their Duties. By EVA C. E. LÜCKES, Matron to the London Hospital. London: J. & A. Churchill. 1886.—Miss Lückes is already well known as the author of some excellent "Lectures to Nurses," and we were prepared to find her present work, which is addressed to hospital sisters, full of sound practical information and advice. Those who are most familiar with the working of hospitals under the modern system of nursing will best appreciate the great importance of a due knowledge of their special duties and relations to other officers of ward sisters. Miss Lückes deals with these matters in a clear and commonsense style, and her book cannot fail to be useful to those for whom it is specially intended. On every page we find evidence of Miss Lückes' thorough acquaintance with all the details of the nursing department of hospital management. From the chapter on the "Relationship of Sisters to their Patients" we extract the following: "One of the most satisfactory conclusions that long experience of all sorts of patients brings to the majority of sisters is that human nature is worthy of greater respect and admiration than they had previously believed." Further on, in urging sisters to welcome with a kindly word all new patients, Miss Lückes writes: "It must be remembered that they (the patients) are not only strange but ill, and often in actual pain, so that they are not in a normal condition for going through the ordeal of being consigned into strange hands, and unless they are too ill to take any notice, which of course frequently happens, the way they are spoken to on their first arrival will make a wonderful difference to them." In reference to the vexed question of patients' friends we read as follows: "The familiar sight of what appears to us a very unattractive, not to say repulsive figure, the harsh sound of a very gruff voice uttering words that to our ear are not very tender or even kindly, the heavy footfall of most ungainly boots, may be eagerly looked for and welcomed by the patient, and may do more to diminish the terrible sense of loneliness that is creeping over him than our gentlest and most sweetly expressed sympathy could do."

The Liverpool Medico-Chirurgical Journal. No. 10. London: H. K. Lewis.—This number contains an instructive article on a case of Congenital Macrostoma and Deformity of the Ear, by Mr. Rushton Parker. The Significance of the Corpus Callosum, by Dr. J. Hamilton, has already been referred to. Sir Dyce Duckworth has written a clinical lecture on Paralysis Agitans, to which Dr. James Barr has appended a case of the same disease. Mr. Robert Jones has contributed an article on the Abuse of Rest; Dr. Emrys Jones, some notes on Iodoform in the Treatment of Eye Disease; Mr. Lowndes, some notes of post-mortem examinations. A special new feature of the journal is the introduction of reports on recent practical advances in medicine and surgery: Antipyretics by Dr. Barr, and Antiseptics by Dr. W. Alexander. The journal is the organ for the Transactions of the Liverpool Medical Institution. Mr. Rushton Parker contributes a paper on Hernia, based upon seventy-four operations. In a paper by Dr. Richard Caton on the Pathology and Treatment of Chorea, we are sorry to find canine chorea and human chorea are not sufficiently differentiated in all varieties. The Pathology of Syphilis is discussed by Mr. A. Barron, and its treatment is the subject of a paper by Dr. James Wilson. Dr. Francis Imlach contributes a paper on Ovarian Abscess and Pyo-salpinx.

THE LANCET.

LONDON: SATURDAY, MAY 22, 1886.

THE wholesale projection of the Privy Council into the affairs of the medical profession is one of the blots of the Government Bill which we have been careful to expose. We are glad to admit that our representations have not been disregarded. The amendments proposed by Sir LYON PLAYFAIR greatly reduce the frequency of the necessity for the sanction of the Privy Council; and undoubtedly, if the Medical Council was one likely to work well, there need be, and there would be, little occasion or excuse for interference. But this is the very point. There neither exists a good Council, nor is one to be created by the Bill. One more direct representative of the profession has been conceded to England, which brings the whole number of direct representatives up to five. Sir LYON PLAYFAIR seems to have felt the force of the objection that the proportion of direct representatives, especially those of England, to the representatives of corporations, was very small, and he has diminished the Crown representatives by one and given it to the registered practitioners. We must be thankful for crumbs when we cannot get half a loaf, but we think that the Crown representatives might well have been reduced to four, and the number of direct representatives raised to six. It is not denied that the original design of Crown members was to secure through the Government the representation of practitioners unconnected officially with the medical corporations, whose excessive and individual representation has been the weakness of the Council, and which unfortunately is not dealt with in this Bill as it was in that of the previous Liberal Government. A further reduction of the Crown representatives would be the more reasonable, as the interference of the Crown, through the Privy Council, is still provided for in the Bill.

Is there any chance of an honest attempt to make the thorough changes in our examining system which have been desired by medical reformers for a generation, and which have been recommended by the Medical Council and by a Royal Commission? We fear there is not. In the amendments printed we see no sign of this. One set of amendments indicates that the corporations are dissatisfied with the favour shown to universities in recognising their right *singly* to grant a complete qualification, whereas the corporations must combine, two or more, to be able to give a full qualification. Sir HENRY HOLLAND represents these amendments, as he does also another to secure and empower the registration of diplomas in Public Health, whether from a university or a medical corporation, Sir LYON PLAYFAIR strangely proposing in an amendment only to register those sanitary diplomas which are granted by universities. We can see no reason for this invidious distinction But all this is a mere fight for pre-eminence between universities and corporations. Any adequate Bill would have recognised the clear distinction between universities and corporations. It would have recognised the view that corporations exist mainly to grant the ordinary licences to practise, while universities exist to grant something more—viz., a Degree—after an examination of a higher character than that minimum examination which has to be passed for an ordinary diploma. It is no less desirable for the reputation of the profession that the universities should be kept up to a standard above that of mere competence than it is that the minimum examination of the corporations should be a sound test of competence. The Bill does not attempt to recognise any such difference in the functions of universities and corporations. It does not, however, treat universities and corporations impartially. It assumes that each single university can grant a full qualification, and that each single corporation is under a disability of granting a *complete* qualification, whatever the completeness of its examinations. We cannot wonder that there should be grave dissatisfaction on the part of the corporations with such an assumption. The London College of Physicians, for example, gives a thorough examination in all branches. Is it to be tolerated that it shall recognise the *necessity* of going into combination with another body before granting a full qualification? It is true that it has chosen for a time, under certain conditions, to act conjointly with the sister College; but to have its disability expressed and stereotyped in an Act of Parliament, and to have the universities placed in the favoured position of granting full qualifications, with no test applied as to the *higher* standard of their examinations, is too much for flesh and blood as it exists in corporations. Let us leave out of view the Corporation and its interests to consider the claims of a man who in this College or any other *single* college has passed an ample and fair examination in medicine, surgery, and midwifery. How can it be right to demand that such a man shall go through the mill of a second college, in the same subjects, and pay a second set of fees? It cannot be right. It is of no use for Sir LYON PLAYFAIR to boast that he is securing complete examination. That is secured in the one College. What he insists on is that two corporations must combine in order to give one qualification. The uninitiated member of Parliament may think this is in the interest of the public. It is not so at all. It is an attempt to maintain two corporations where only one is wanted, and to do so at the expense of the medical profession in perpetuity. The corporations are selfish in the matter, and if they rebel now it is because they are offended at the superior position of the universities in the Bill, which deserves to fail for want of thoroughness. There is also the risk of all the corporations that have hitherto been condemned to give only single diplomas taking advantage of Clause 5, and with assistant examiners from the Medical Council giving a qualifying examination—a risk, of course, that involves a great number of different and competing bodies, which it will be difficult and very

Digitized by Google

costly to supervise. Finally, there is the great defect in the Bill of any serious attempt to strengthen the penal clauses for using false titles and for various forms of sham and deceptive practice. At coroners' inquests and in the law courts we are constantly and painfully reminded of the necessity for such a change in the penal clauses, and yet the subject is neglected by the Government and left to be dealt with in the Bill of a private member.

THE lives of WILLIAM CHESELDEN and ANTONIO SCARPA are the themes of interesting studies by the eloquent and sympathetic pen of Dr. B. W. RICHARDSON, in the last two numbers of his *Asclepiad*. While doing justice to rare powers and enduring work, he has not entered into many biographical details, of which some are worth recalling. Best known as an anatomist, and for his method of lateral lithotomy, CHESELDEN was so good an artist that Putney Bridge and the Surgeons' Hall at the Old Bailey were erected after his designs. The operation for artificial pupil which he originated was first performed in 1728, the very year of JOHN HUNTER'S birth. Twenty-one years later, as recorded by their contemporary, BENJAMIN HUTCHINSON, in his "Biographia Medica," CHESELDEN, at the request of Dr. WILLIAM HUNTER, allowed his brother JOHN to attend him at Chelsea Hospital for his first lessons in the rudiments of surgery. CHESELDEN had been himself fortunate in his early training, as he was a resident pupil of the distinguished anatomist and surgeon, WILLIAM COWPER, best remembered for the glands which bear his name. It is no disparagement of JOHN HUNTER'S merits to dwell on the rare advantage which attended his entrance into the profession under three such masters as his brother, WILLIAM CHESELDEN, and PERCIVAL POTT. ANTONIO SCARPA'S fortune was in kind similar, for he was the favoured pupil of G. B. MORGAGNI, who in his classical work "De Sedibus et Causis Morborum," laid the foundation of pathological anatomy and clinical medicine, as pillars of the modern medical edifice. When stricken with blindness, MORGAGNI chose SCARPA for his assistant and secretary; and they found common intellectual solace from their severer studies, in the Latin classics for which MORGAGNI had had a life-long predilection and SCARPA had shown very early aptitude. All the great men to whom we have incidentally referred were scholars, with the solitary exception of JOHN HUNTER whose youthful days appear to have been wasted in the Grammar School of Long Calderwood, his birthplace; he never seems to have acquired or cultivated a taste for literary pursuits; while SCARPA, who most closely rivals him for depth and variety of anatomical, physiological, and surgical research, was a writer no less elegant than prolific. His letters to HENRY WEBER, of Leipsic, "De Gangliis Nervorum, deque origine et essentia Nervi Intercostalis," are models of pure Latinity; and he appears a worthy countryman of METASTASIO in his biography of GIAMBATISTA CARCANO LEONE, the favourite pupil and devoted assistant of GABRIEL FALLOPIUS.

Latin and Italian were equally familiar to SCARPA with pen and speech; and he mastered English, French, and German in the wide scope of his reading, and by not only visiting, but working in, the European capitals. In Paris FRÈRE CÔME, VICQ-D'AZYR, and WENZELL; at Gottingen, BLUMENBACH, RICHTER, and WRISBERG, were his masters; in London he studied under the HUNTERS and PERCIVAL POTT; and, curiously enough, first learned from CRUIKSHANK how to display the lymph by injection with mercury, although the existence and function of these vessels form one of the many discoveries justly due to the Italians. Early association and animated rivalry with GALVANI at Bologna must have acted as a very potent stimulus to SCARPA'S taste for physical research, in cultivating which he had the incalculable advantage of long colleagueship with VOLTA when their powers were ripest.

Hypogastric lithotomy was the object of special studies, both by CHESELDEN and SCARPA. The former takes precedence not merely in date but for the importance of the treatise which he published in 1723 on the High Operation for the Stone. This volume deserves special notice at a time when the procedure which it describes is enjoying the favour common to revivals. The book having no index or table of contents, a superficial observer is apt to look upon the 180 pages of which it consists as devoted to CHESELDEN'S practice; but this, with a careful anatomical description, cases, and ten plates, only comprises thirty-three pages besides the preface, from which one passage may be quoted in evidence of CHESELDEN'S candour and modesty: "In my own account of this operation I have fairly set down everything that I judged most material to be known, without the least disguise or partiality to myself, and that the reader might see what had been before done, and that I might not be suspected of arrogating to myself any part of this operation." In one of the quoted cases two stones were removed above the pubes from a gentleman aged about seventy. The stones weighed a little over four ounces each, and the patient recovered without any bad symptoms. The remainder of CHESELDEN'S treatise under notice is devoted to translations of memoirs on the same operation by PIERRE FRANCO, DIONIS, HILDANUS, and other masters, concluding with a short original appendix from CHESELDEN'S pen entitled "Two Cases to show that Wounds into the Abdomen are not exceeding Dangerous, though the Guts should appear or Thrust out at the Wound." In one of the cases (a female aged seventy-three), with gangrenous umbilical rupture, CHESELDEN found her "with about six-and-twenty inches and an half of the gut hanging out mortified. He took away what was mortified, and left the end of the sound gut hanging out at the navel, to which it afterwards adhered, and she recovered."

Although CHESELDEN'S life-work must ever remain an integral part of the history of surgery, his name is unaccountably omitted from the last edition of the "Encyclopædia Britannica." Like SCARPA his rise was rapid. At twenty-three our countryman was F.R.S., and at twenty-two the Italian was appointed to the chair of Anatomy in the University of Modena. Academic honours and wealth fell to the lot of both. The French Academy of Sciences paid CHESELDEN the rare compliment of deputing SAUVEUR MORAND to visit London to study and report upon his method of lithotomy, and at the foundation of the Royal Academy of Surgery in Paris CHESELDEN was elected by acclamation its first foreign associate. On SCARPA NAPOLEON conferred the order of the Iron Crown; and then, as a special token of regard for his talents and his independence, released him from the obligation of taking the

Digitized by Google

oath of allegiance, to be free from which he had absented himself from Pavia. Not so equal was the fortune of the two great surgeons in survivorship. CHESELDEN, like the two HUNTERS, died within a few months of sixty-five. SCARPA reached eighty-five, close upon the age of his first master, who touched eighty-nine. It has been said that eminence is often a question of survivorship, a proposition capable of wide illustration, but with many notable exceptions in science as in the arts. DUPUYTREN died at fifty-seven, VESALIUS at fifty, BICHAT at thirty-one; yet, looking down the life records, in their published works, of such men as MORGAGNI and SCARPA, it is inconceivable that they could have accomplished what they did, had they not been endowed with most vigorous constitutions and spared to patriarchal age.

Twelve pages of Dr. RICHARDSON'S *Asclepiad* article, already referred to, are devoted to SCARPA'S labours, and the erudite record is certainly a prodigious one. For fertility amongst anatomical, physiological, and surgical writers, ANTONIO SCARPA has scarcely a rival besides CHARLES BELL; but, contrary to what might be predicated from their nationality, the Italian excelled in calm observation and rigid induction. Both were marvels of versatility; but BELL was too imaginative and impressionable to reach the philosophic standard, towards which SCARPA toiled with fixed gaze and unfaltering step.

ON Tuesday next, the 25th inst., an extraordinary meeting of Convocation will be held at Burlington-gardens at 5 P.M., for the reception and consideration of the report of the Special Committee which was appointed in December last, on Mr. MAGNUS'S initiative, after Lord Justice FRY'S scheme had been rejected. The report of this committee of twenty-five follows so faithfully on the lines laid down in Mr. MAGNUS'S circular of Dec. 1st, 1885, and is so evidently a mere amplification of that circular, that we might have been spared the suspense and waste of time. In reviewing his proposals on their appearance, we pointed out that with the exception of the last two—viz., the question of professorships &c. of higher education, and a fixed State endowment,—they might practically run on all fours with those whose details were worked out by Lord Justice FRY; and this opinion has been fully borne out by the present draft scheme. We find in it no such differences from that presented by the former committee as to justify or even to excuse the action of those members who are responsible for its production, who in November last voted against Lord Justice FRY'S amended motion, "That the House now consider what amendments, if any, be made in the said scheme, and that such amendments, if any, be made in the form of instructions to a committee of revision." A Council of Education, with some members elected by the separate faculties in Convocation, as a weak and clumsy substitute for proper faculties and boards of studies; an indefinite for a precise indication of what are to be constituent colleges; the omission of the words "in or near London" in reference to the colleges; and a direct addition of two members by Convocation to the Senate, are the main alterations suggested by the new committees. Six months have been allowed to pass by, so that these details might be worked into the scheme, and permit it to go forth to the world under its present auspices, whereas they might properly have been discussed as amendments when Lord Justice FRY'S plan was under consideration. The outcome is a little less power and influence for the teachers, and a fractional increase of them for Convocation. We hope that the jealousy of the graduates may be allayed by these concessions, and that this scheme may pass, although we much prefer the former one. Any scheme which will secure a more intimate association between university examination and university teaching, and which will confer a substantive voice in the government of the University upon the teachers and examiners, is so far preferable to the present chaotic condition of higher education in London, that we shall not cavil at its details, or at the safeguards by which it has to be surrounded out of deference to the distrustful attitude of some graduates and senators. It can only be adopted by Convocation as a basis of conference with the Senate, and is sure to undergo considerable modification before that body consents to apply for the new charter into which it can be embodied. The proposals for promoting higher education and for obtaining a fixed endowment from the State are good and easy of adoption, and we only hope that the money may be forthcoming; but it is at least doubtful whether the conferring of honorary degrees will not be a great mistake.

Annotations.

"Ne quid nimis."

HOMES OF THE WINDSOR POOR.

AN article in the *Morning Post*, calling attention to the need for the sanitary improvement of certain parts of Windsor, has been the subject of warm discussion by the Town Council of that borough. We gather from a report of recent proceedings of that body that the misfortunes which accrue to the inhabitants of unhealthy areas are shared, though doubtless to a less extent, by those of their fellow-townsmen who are better circumstanced. The reputation of a town must have its influence upon trade and general prosperity; and it is indeed fortunate that this should be so. Where a local authority is negligent in enforcing all the powers that it possesses, it deserves to be thought of as one that is careless of the health interests of the community; and the injury which results from this opinion is often an incentive to work which should be undertaken from a higher motive. If Windsor is suffering from loss of trade, the remedy is in her own hands. The Council cannot be surprised if holiday-makers, in choosing a locality which they intend to visit for the purposes of health and recreation, have some regard to its sanitary condition. A town may have many natural advantages, but if it have within its districts that which may serve to foster disease, there is an element of risk to visitors as well as residents which cannot be overlooked. Windsor, therefore, for every reason, should proceed without delay to put itself in order; and this, we understand, the Royal town is going to do; but time is passing, and in the meanwhile the reputation of the town suffers. It has been proposed that the reconstruction of the old and defective portions of the town should be undertaken in honour of the Queen, during her year of jubilee. The thought is worthy of a Royal borough which has within it an ancient Castle of which England is proud, and which is a residence of the Sovereign. But it is high time that a substantial beginning of this project should be made; unless this is done, we fear that Windsor will not regain the confidence she has lost.

THE NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

ON Thursday, May 13th, this Association were hospitably entertained by the Mayor and Corporation of Salford. Dr. Tatham, the medical officer of health for the borough, introduced the members and associates to the Mayor and Chairman of the Health Committee, at 2 P.M., at the Town Hall; and after a champagne lunch had been disposed of, the party proceeded in conveyances to inspect the Winton Fever Hospital, the disinfecting station, and the extensive sewage-works at Mode Wheel. Mr. Jacob, the borough engineer, courteously acted as guide over the works, explaining the details of the process adopted (mixing the sewage with lime and turning it into tanks to settle), and then invited those present to adjourn to the board-room, where coffee was served. Here Dr. Tatham delivered an address on the Notification of Cases of Infectious Disease and their Isolation in Hospital as practised in Salford, and passed in review the steps taken by the Sanitary Authority for the improvement of the sanitary condition of the town. In the course of his remarks he stated that in 1867, when the Local Health Committee first came into existence, the average annual death-rate of the borough was not less than 31 per 1000 of the population; whereas in the five years ending 1885 the average annual death-rate was less than 23 per 1000. At the close of Dr. Tatham's address, Dr. Kenyon, of Chester, congratulated the Sanitary Authority on being so ably advised, and on the public spirit displayed in attempting and achieving so much for the health of the community. In the name of the North-Western Association of Medical Officers of Health, he heartily thanked his Worship and the Corporation for their hospitality and courtesy. Mr. Vacher, of Birkenhead, endorsed all that Dr. Kenyon had said. The result of the efforts made at Salford should encourage other urban authorities to be as active and persevering; and it might be that one effect of the Mayor's invitation would be to introduce sanitary reforms into districts where hitherto little had been done, and where neither hospital accommodation nor disinfecting apparatus were provided.

PHYSIOLOGICAL EFFECTS OF MASSAGE.

DR. F. GOPADZE has published a series of observations undertaken with a view to determine the effect of massage on the transformation of the nitrogenous principles of food. He has investigated the history of the subject, and finds traces of it in a Chinese work 3000 B.C. Dr. Gopadze finds that though there has been a general tendency amongst authors to assume that massage increases the assimilative power, no exact observations on the subject have hitherto been published. He therefore obtained the co-operation of four medical students, who for three consecutive weeks became inmates of Professor Manassein's clinic, and lived on certain articles of food—bread, milk, soup, veal, and roast beef, the quantities ingested being accurately noted. The nitrogen in all the samples of food, and in the fæces and urine excreted, was determined by the Kjeldahl-Borodin process. Massage was practised for from twenty to twenty-five minutes once a day two or three hours after food. The operations were commenced by *effleurage*, beginning from the extremities and working towards the centre. This was followed by *massage à friction, pétrissage, tapotement*, a second *effleurage* of each part concluding the whole. The temperature was subsequently taken, and in some cases sphygmographic tracings. In all four cases the appetite was decidedly increased, not only during the week in which massage had been practised, but after it had been stopped; thus, one of the subjects took an average daily quantity of 24·95 grammes of nitrogen during the first week, 30·97 during the second or week of massage, and 29·57 during the third week. Similarly the amount of nitrogenous transformation was augmented during the continuance of massage in all four cases. The augmentation persisted in two of the cases, but in the other two the transformation was less during the third than during the first week. In Case 1, the nitrogenous transformation was increased 3 per cent. during the second week and 1 per cent. during the third. In Case 2 it was increased 1 per cent. during the second week, but diminished 11 per cent. during the third. In Case 3 it was increased 3 per cent. during the second week, but diminished 10 per cent. during the third. In Case 4 it was increased 4 per cent. in the second week and 3 per cent. in the third. The quantity of nitrogen assimilated increased in all four cases, independently of the amount of food ingested. During massage two of the subjects gained slightly in weight, the other two losing weight; but during the week following the one in which massage was practised all four gained. The axillary temperature decreased for about half an hour after the operation to an extent varying from 0·1° to 0·5° C., after which it began to rise, attaining its original figure, or from 0·1° to 0·3° below it, about an hour after the end of the *séance*. The respirations became more frequent, and were of a deeper character. The effect on the pulse varied with the character of the massage. When this was carried on lightly, the pulse became more frequent; but when the manipulation was more forcible, the pulse became slower. The effects in both cases persisted for an hour or more after the termination of the operation. In conclusion, the author suggests that massage should prove useful in chronic gastro-intestinal catarrh, in chronic constipation due to an atonic condition of the intestines, also in various cases where there is a lack of tone in the abdominal muscles. He also thinks that the practice of massage should be a subject of instruction not only in the Military Medical Academy of St. Petersburg, but in all the medical faculties of the empire and in the institutions for training "feldshers"—a semi-educated class of men who act as hospital sergeants, and after retiring from the army are put in charge of village communities where there is no medical man.

HOUSES LET IN LODGINGS.

THE vestry of the parish of Bermondsey last week obtained a conviction of the owner of a house in Long-lane for a breach of one of the vestry's regulations as to houses let in lodgings. The house had been registered, and the requirement to prevent overcrowding was that no room should be occupied that did not provide 300 cubic feet of air space for each adult or two children if used as a sleeping room only, and 400 cubic feet if used for day purposes as well. The inspector appointed to enforce the Act found that in four rooms the number of inhabitants was such that this amount of cubic space for each individual was less by fully one-third than it should be. The magistrate inflicted a fine of 20*s.*, and 6*d.* a day for forty-nine days during which the regulation was disobeyed, and stated that this mitigated penalty was due to the defendant's plea that "she was no scholar, and had erred in ignorance." It was stated that this was the first conviction under the Act which empowers the regulation of lodging-houses, and if this be the case, an Act which offers the only effectual remedy for preventing overcrowding in this great city, has been allowed to be inoperative for twenty years. Doubtless overcrowding can be dealt with apart from regulations, but the tedious process of serving notices, of obtaining a magistrate's order, and only procuring a penalty when this order is disobeyed, would have rendered the employment of a much larger staff necessary than the vestries have been willing to provide. The result has been that overcrowding has remained to a great extent unchecked, but the ease with

Digitized by Google

which this difficulty is overcome by the adoption of regulations under the 35th section of the Sanitary Act of 1866, in enabling the vestries to obtain a penalty within a few days of the discovery of the offence, should commend these powers to every authority that desires to do its work efficiently.

THE MICROZYMES.

THE battle of the microbes, which has been raging for three months in the French Academy of Medicine, is now brought to a close, and for some time we may expect peace from leucomaines and microbes. To estimate which side has the advantage is not a difficult task. Microbes have too sure a footing to be easily displaced from our etiological catalogue, though from time to time their exact place may be subject to variation, as our knowledge of their life history becomes more complete or our acquisitions of new factors increase. Among the many discourses that the discussion elicited from members of the Academy, the longest was that of M. Béchamp, who, without being exactly a microbist or antimicrobist, reconciled the external and internal (if we may be allowed the expression) origin of disease by the theory of microzymes. According to this idea, every animal cell, its nucleus and nucleolus, and every description of cell, whether white blood-corpuscle, or gland, or epidermic cell, is composed of elementary particles visible to us under the microscope as granules, to which he applies the term microzymes. These have a life and being of their own, and by this fact the life of the cell is maintained; but when the cell itself comes to an end and is disintegrated the microzymes live on, and when free are known to us as bacteria. They may change their form and aggregate, giving rise in this way to the many kinds of micro-organisms that have been described in the order Schizomycetes, such as vibriones, spirilla, &c. The physiological action of these microzymes varies according to the media in which they are developed, and in this way the noxious forms may be rendered innocuous, as seen in Pasteur's cultivation of rabietic virus, or *vice versâ*: the innocent microzymes may under certain bad conditions become virulent, of which such diseases as typhus, small-pox, &c., afford an example. The theory is no doubt attractive, and serves to supply some vacant places which the microbian idea leaves, but will it bear the test of experiment—that is, does such a thing as a microzyme exist? The matter has been placed in the hands of a commission, and we await the verdict.

DWELLINGS OF THE POOR.

A DEPLORABLE account has recently been published of two houses in Warren-street, St. Pancras. In one of these the drains were apparently entirely stopped, and the sewage, running all over a back yard, percolated through the kitchen wall and accumulated underneath the floor. In the front area, it was stated, the objectionable matter likewise declined to run through the drains owing to the traps being defective, and consequently added to the accumulation under the flooring. On the application of the vestry's officers, Mr. Mansfield made an order for closing the houses until the necessary repairs had been executed, and imposed a fine of 25*s*. It is worthy of notice that this large parish has nearly 25,000 houses, that a very large number of these are let out in lodgings, many of them occupied by the poorest and most destitute people, yet for the purposes of carrying out the various Acts of Parliament, the Food and Drugs Act, Canal Boats Act, the Factory and Workshops Act, all the Acts dealing with infectious diseases, and the inspection of houses of all kinds, four inspectors only are employed. In proportion to population there is not more than one inspector to 60,000 persons, and yet it is pleaded that London vestries are not negligent of the duties which devolve upon them. When it is recollected that for each case that goes before the magistrate the inspector must pay several visits to the house before the nuisance is finally abated, some idea can be formed of the insufficiency of the staff to maintain the parish in a proper sanitary condition. But St. Pancras is not exceptional; there are other parishes where the staff is not more numerous, and recent events have certainly not shown any desire on the part of the local authorities for more effective sanitary administration. Londoners can only be grateful for what is done in the absence of something better.

THE DANGER OF TUBERCULAR AFFECTION FROM COWS' MILK.

PARIS cows are said to have been found to be producing milk which contains the bacillus of tubercle, and the Council of Health have advised the closing of all cowsheds in the city. It is believed that the conditions under which these animals are kept have contributed to the production of this disease, and it is hoped that the milk of animals living in country farms is less open to objection in this respect. Of late years much has been done to improve London cowsheds, but the question certainly deserves consideration whether the inhabitants of this metropolis are not exposed to the same risk as are those of Paris. At the present time there are in London more than 800 cowsheds, and the amount of milk distributed therefrom is very large. If it could be definitely shown that London milk is more prone to contain tubercle bacillus than that coming from the provinces, there would be much reason for the Metropolitan Board of Works to follow the same course as that pursued by the Paris authority. It may be found that of the evil effects of milk, of which we have heard much lately, that of the production of phthisis is the greatest; but the power which every householder possesses of protecting his family by boiling all milk which comes upon his premises is so easily within his reach that it is matter for regret that the practice of milk-boiling is not more general.

THE TREATMENT OF YELLOW FEVER.

SENOR ADOLFO MARTINEZ CERECEDO, of Puerto Rico, in an article in *El Siglo Medico* on Yellow Fever, argues that, as Dr. Freire of Rio de Janeiro has demonstrated the existence of cryptococci in the blood, vomit, &c., and as the micro-organisms producing most infectious diseases appear to obtain entrance by the gastro-intestinal tract, the abortive treatment by emetics and cathartics would seem to be the most rational, though much objected to by many South American practitioners. In addition to the emetics and cathartics, Señor Cerecedo advises that hot infusions of mallows or of oranges and lemons should be administered, the heat and the acidity being prejudicial to cryptococci and mycelia. He remarks here that Pacini and Koch have shown that the cholera bacillus dies rapidly in a medium only slightly acidulated, and that Bucholtz and Falk have observed that certain acids prevent the development of the different micro-organisms which set up abnormal fermentation processes in the stomach. Added to which, he has himself noticed from his experience in Puerto Rico that those persons who habitually drink lemon-water enjoy more immunity from yellow fever and malaria than those who abstain from acid liquids. He quite agrees with Dr. Freire as to the effect of salicylic acid on the yellow fever poison, and he advises that the soda salt should be given from the second day, and diaphoresis encouraged by hot drinks and external stimulating liniments. As an ordinary drink at this time lemon-water may be given, which, if nausea exists, may be iced. If the third day brings the remission with diaphoresis, the cold drinks should be replaced by hot. If

Digitized by Google

the abortive treatment does not prove effectual and the serious symptoms of the second period supervene, he advises recourse to the ordinary methods of treatment.

COMPULSORY SWIMMING IN SCHOOLS.

A FEELING has for some time been steadily growing that all healthy persons should be able to swim, and a good number, at all events, of our schools which are favourably situated include this most useful art in their curriculum of education. Compulsory instruction in swimming has found favour with some continental communities, and indeed there is much to be said for such a course. All children, as is well known, do not take readily to bathing, while of those who do some never take the trouble to learn to swim. Thus it comes about that persons who have spent their lives at the coast—many fishermen, for example—are helpless when immersed in deep water. There is reason therefore in the argument that swimming should form a regular part of school training, and should be compulsory on boys and girls alike, who are not disqualified by bodily infirmity. Even children of poor physique, if not vitally damaged by disease, will often benefit by such a course. Not only is the vigour of every organ and tissue stimulated by the bracing chill of cold bathing, but the skin surface which is cleansed from the products of its excretion must also subserve, much more effectually than one which is not, the nutrition, purity, and working power of the more active organs. Health, without doubt, is largely indebted to a clean skin. In swimming we have these various physiological advantages with that of muscular effort added, and when we think again of its great utility in case of such accidents as every summer invariably brings us, we cannot but plead that the kind compulsion exercised abroad may also be applied at home. Many of our largest towns have the sea or an estuary close at hand, while inland populations which have not this advantage are seldom without one or more swimming-baths.

THE ETHICS OF HANGING.

A PARLIAMENTARY enthusiast on the subject of abolishing the death-penalty some years ago described the issue raised as "a poor man's question." It is impossible not to feel that, setting aside all considerations of class distinction and privilege, this is an inadequate account of the matter. Even granting that the gallows is a terror to the poor rather than to the rich—by no means an accurate proposition—the well-to-do and law-abiding sections of the population have fully as much interest in the questions whether it is expedient to punish capital offences by death, and if so, how the extreme sentence of justice should be executed, as the probable or actual victims of the penalty. It is not perhaps strictly within our province to determine whether the fear of death does operate as a deterrent from crime, although we have the deep interest common to all citizens in this issue, and it will be conceded that, as members of a profession brought into close relation with all classes of the community, and compelled to study human nature in its secret workings, and as an hereditary estate and organisation, medical men have exceptional opportunities of forming a judgment on that point. We incline to the belief that the death penalty *is* deterrent in its effects, although not so much on men or women who are on the verge of committing deeds of violence as on those who, were there nothing to fear, would drift into homicide; and on this ground we are not prepared to urge strongly that the time has arrived at which the State may safely decide to put no more malefactors to death. Whatever may happen in the future, the old Levitical law cannot at present, we fear, be safely superseded. The comparative immunity which this country enjoys from habitual or prevalent crime of the homicidal class is, doubtless, in large measure due to the fact that murder is punished by the ignominious death of its perpetrators. This rule, even though there may be many exceptions, has certainly a wholesome influence on the manners of the population generally. It is shameful to kill, and therefore it is accounted shameful to do acts which may lead to killing. Our more immediate concern, however, is with the manner of executing the law as it stands; and, looking at the whole facts of the case from a physiological as well as a moral point of view, we doubt whether there is any more suitable mode of taking life for judicial purposes than that of hanging by the neck, provided always that the process is carried out with the skill due to humanity. Many alternative means have been proposed, such as destroying life by passing a current of electricity through the body, or by the deprivation of oxygen, or the use of some lethal chamber. Meanwhile we decidedly incline to the opinion that, instead of depending on a public executioner for the carrying out of the death sentence, it would be better, as suggested by the author of a recent magazine article on this subject, to adopt a well-considered general rule of procedure, and to have the penalty inflicted by the warders of our prisons. It is humiliating to society to employ a particular individual to hang the condemned. Better far let the infliction of this penalty, as of others, be a strictly official act performed by the authorities of the prison as other penalties are inflicted. A committee might be appointed to draw up a set of rules which should be carried out strictly. The last act of justice would gain in dignity, and the interests of humanity would be secured by this reform more effectually than by any other which public opinion has yet been asked to consider and approve.

TREATMENT OF ACUTE RHEUMATISM.

THE last number of the *Russkaya Meditsina* contains a communication from Dr. L. Grinevitski, of Rostoff-on-the-Don, who writes that for more than twenty years he has treated acute articular rheumatism with nitrate of potash, two drachms being given daily in raspberry syrup, and a dose administered every two hours. Together with this internal medication he prescribes an ointment for use morning and evening of the following composition: Olei hyosc., 1 oz.; ung. hydrarg. cinerei, 2 dr.; ext. acon., 1 dr. He has tried all ordinary remedies, and finds that on the whole this plan of treatment is more satisfactory than any other, being especially valuable in those cases where salicylates fail to give relief. Generally the disease is brought to an end in from one to two weeks, according to its severity and the time the treatment was commenced. When commenced at the onset of the attack, and before more than one joint was affected, the others were usually spared altogether.

A NEW PLAYGROUND FOR LONDON CHILDREN.

LONDON is not yet so well supplied with public gardens or other open spaces but that another is at any time both acceptable and useful. Attention has lately been directed to the waste ground which lies to the west of the Law Courts, and which is not at present required for the extension of these buildings, on account of its fitness for a temporary recreation-ground. Several reasons combined render it very desirable, in our opinion, that the opportunity thus presented should not be overlooked by those who are interested in the well-being of the poorer town children. The space in question lies in the heart of a populous district, where dirt and overcrowding are almost unavoidable; it is required for no other purpose, and it might at a very moderate cost, in seats, gymnastic bars, and the like, be made to contribute to the healthy growth of many who rarely if ever see the country. We heartily commend this project to the attention of the Public Gardens Association.

GLASGOW ROYAL INFIRMARY AND THE UNIVERSITIES (SCOTLAND) BILL.

OUR Glasgow correspondent writes:—There is a movement on foot to obtain the recognition of the Royal Infirmary Medical School as a College of the University. A proposal that such a recognition ought to be extended to this school comes up for consideration at the next meeting of the Glasgow University General Council. In the meantime the managers of the infirmary have sent a memorial to the Lord Advocate and to the Secretary of State for Scotland, suggesting that in the forthcoming Universities (Scotland) Bill a clause should be introduced embodying the change above indicated. Reference is made to the breaking up of the connexion between the University and the Royal Infirmary in 1875, when the former institution was removed from its old site in the High-street, near to the infirmary, to the extreme west of the city, where it has the Western Infirmary on which to depend for clinical teaching. The Royal Infirmary has a complete staff of able teachers, most suitable accommodation and equipment (provided in 1882, in the form of an extensive range of new building, costing over £6000), and large clinical resources (550 beds) but very few students; and it is thought that there is little likelihood of any increase in the number of students, to whom this magnificent store of clinical material might be made available, so long as the infirmary school continues to bear to Glasgow University the relation simply of an extra-mural teaching establishment. The memorialists, therefore, urge that Glasgow University should follow the example of Oxford and Cambridge in recognising as colleges schools outside its own walls. There would then be in Glasgow a strong eastern and a strong western school, and the present overcrowded condition of the Western Infirmary wards would be relieved, to the advantage of clinical teaching all round.

QUARANTINE IN ITALY.

La Società Italiana d'Igiene (the Italian Society of Hygiene), whose seat is in Piedmont—that is, in the most enlightened province of the peninsula—held on the 5th inst. an important and prolonged discussion on the efficacy of quarantine, and embodied its conclusions under the following three heads: 1. Experience of quarantine as enforced during the last two years demonstrates that cholera cases afloat and in quarantine stations are extraordinarily rare when it has been possible to preclude the infection from being introduced with soiled articles worn by the passengers or by the crew, or from its being borne with the ship's cargo. 2. Assiduous surveillance of persons practised by the medical officer on board, and the rigorous disinfection of soiled articles in the ship, also practised by him under his own responsibility, are sufficient safeguards against cholera germs being in this way transmitted from place to place. 3. The conditions nowadays of passing to and fro, and the manifold means of communication by land between one Italian seaboard and another, have this effect: that quarantine afloat, even if its utility could be shown, can be eluded by anyone whose commercial engagements make it worth his while to pass from one port to another by sea-route. Hence the fact that quarantine resolves itself simply into a grave impediment to our commercial activity afloat, with that most disastrous of consequences in times of epidemics—to wit, the misery of the seaboard population. These positions, which have long been truisms in England and her dependencies, have finally been accepted by scientific Italy, but politics interpose to set them aside. Seven days' quarantine must, it seems, be fulfilled by all who—from whatever part of the peninsula, to go no further—have occasion to visit such Italian islands as Sardinia and Sicily, and this because in the forthcoming elections it would go hard with Government candidates if the Minister of the Interior failed to humour the prejudices of these backward populations. The indignation of *Il Diritto*, a high-class Roman journal, finds vent in a special article, the tenor of which may be inferred from the following:—"The condemnation passed by science on quarantine, and the inefficacy of the precaution as demonstrated last year, are not enough to spare us these vexatious provisions. In spite of science, in spite of experience, the Minister of the Interior, through his chief secretary, Signor Morana, has political reasons in readiness to justify the opportuneness of 'precautions' rejected by common sense." Our readers may remember that this same Signor Morana issued at the close of the year a report on the last two visitations of cholera in Italy, which was noticed in THE LANCET of January 9th. Nothing could be clearer than his exposure of quarantine as worse than useless.

PARALYSIS OF LARYNGEAL MUSCLES.

THE generalisation so strongly upheld by Dr. Felix Semon, that the abductor muscles of the larynx are more prone to paralysis than the adductors does not carry us a great way but it is very useful as a step to further knowledge. A general cause acting on the recurrent laryngeal nerves appears always to paralyse or weaken the abductor muscles before or more than the adductor. M. Charazac records a case in the *Revue Mensuelle de Laryngologie* of cystic goitre associated with unilateral paralysis of the adductor muscles of the larynx consecutive to compression of the right recurrent laryngeal nerve. During expiration the larynx appeared to be perfectly healthy; the vocal cords left the middle line in a natural manner, so that the glottis presented its normal triangular outline. But during phonation the left vocal cord closed up to the mesial line in good form, but the right did not approach its fellow. We think M. Charazac lays too much stress on his single observation, supposing that to have been a true one, and not to be explained by other causes than the one to which it is attributed. So far the generalisation to which we above referred seems to have been confirmed and strengthened by numerous and carefully observed cases.

CHEAP FOOD FOR HARD TIMES.

WE have satisfaction in observing that the cheap dinner movement has extended beyond the limits of the Board School. It is high time that some attempts were made to effect such a reduction in the price of food as will enable many who have been thrown out of employment through the widespread depression in trade to obtain at least the bare necessaries of life. There are not wanting, indeed, indications that the provision trade in its various branches, between the pressure of competition and a general shrinkage of income, has had to forego a part of its former liberal turnover in deference to the requirements of the time. This is in some ways rather a matter for congratulation. It is a change which comes directly in the interest of the poor. It cannot, however, meet the needs of the most urgent cases, and a special interest therefore attaches to a system which is said to reach even to these, and has been found to work well under the now familiar management of the Vicar of Gateshead. Mr. Ede finds that he can supply a substantial lunch or small dinner of soup, pudding, or pie at the cost of 1*d.* to 2*d.* A really good dinner of two courses, including meat, can be given for 6*d.* The heating and cooking expenses incurred amount to 1*s.* 6*d.* per day. The management of this useful departure in social economy is carried out on ordinary commercial principles, and is in the hands of £1 shareholders, who already, we are told, receive a dividend of 5 per cent. on their investment. An experi-

Digitized by Google

ment such as this deserves to be repeated on a much larger scale. Should it succeed, it will justify a hope that under no circumstances of depression can it be impossible to guard the poor of this country as a class against absolute starvation.

THE MARTYROLOGY OF MEDICINE.

A HOLIDAY contributor writes on the 13th inst. from Florence:—"Passing through this loveliest of cities, I find it in all its ranks, professional and lay, affected with a sadness that refuses to be comforted, even amid the exhilaration of a Tuscan spring. Marino Rossetti, the right hand of Professor Federici in his clinic, attached for more than a year to the Military Hospital, the *facile princeps* of his fellow-students, already crowned with the first prizes of the career on which rare ability and indomitable working power had launched him, succumbed yesterday to the most honourable of wounds. A patient, it appears, on his way to the hospital, had died on the stretcher on which he was carried. For two days, by some unaccountable remissness, the body had been allowed to lie untouched in the dead-house, and on the third day, when it was already far gone in putrefaction, an order came from headquarters for an immediate necropsy. Those whose business it was hesitated to carry through the examination, but Rossetti, when appealed to, undertook it at once. He had barely concluded the work when he saw he had, in his haste, inflicted a slight abrasion on one of his fingers, which had come in contact with the cadaveric ichor. He cauterised the part forthwith, remarking jocularly 'Se saranno rose, floriranno' ('If there are to be roses, they will bloom'), little dreaming of the cypress, still less of the laurel. In a few days pyæmia in a very aggravated form declared itself. Professor Federici, his master, and Professor Corradi and Dr. Pedrazzani, his friends, bestowed all their skill and care on him. His colleagues relieved each other day and night by his pillow, and his young wife was unwearied in such tendance as she could give. But in vain. At six o'clock yesterday morning his prolonged struggle, borne with the manliest endurance, was at an end, and with it a career as bright as it was brief."

THE PARIS SANITARY EXHIBITION.

THE sanitary exhibitions held at Berlin, Geneva, and London have inspired the French Society of Public Medicine and Professional Hygiene with the desire to impart similar practical lessons to the Paris population. With the assistance of the State and the Municipality this most active and able sanitary association of France has succeeded in organising a very creditable Exhibition. It is located in the Caserne Lobau, immediately behind the Hôtel de Ville, a building which up to the present time has been known as the place where hundreds of unfortunate prisoners were shot without trial when the Versailles troops entered Paris. Now this structure is devoted to illustrating the means by which life can be saved or prolonged. The exhibition is notable for its purely technical or scientific character, and the total absence of all trading element. In this it compares favourably with the recent Health Exhibition held at South Kensington. But, on the other hand, it is much to be feared that the knowledge it is desired to convey will not spread very far. There is nothing to attract the general public, to whom the meaning of the various exhibits must remain totally incomprehensible. Ninety-five, if not ninety-nine, of every hundred Parisians do not know what constitutes a syphon, they fail to realise the necessity of such a trap, nor do they understand that gas can travel up a soil-pipe and be a danger to health. These elementary facts are taken for granted by the exhibitors; but being ignored by the visitors, the latter cannot feel any interest in the various combinations of traps, ventilators, flush-tanks, and plumbing work. The structure at South Kensington representing a sanitary and insanitary house was a far more effective exhibit for the purpose of illustrating elementary principles of house-drainage. There is time still, however, to considerably improve the exhibition in this respect. Written explanations should be suspended here and there, and the catalogue could easily be converted into a brief treatise on sanitation. One of the most effective lessons given is that relating to the Paris water-supply. Three glass tanks stand side by side, each containing a cubic metre of water. In the centre there is the absolutely transparent drinking-water of the Vanne, on one side the opaque greenish-yellow water of the Ourcq canal, and on the other the grey, turbid water of the Seine. In a small glass the difference would be scarcely perceptible; but when thus shown in the bulk, the Parisians will see how essential it is to abandon the Seine and the Ourcq as supplies of potable water. This necessary reform is not yet fully accomplished. With respect to the individual merit of the various exhibits, we must reserve our opinion for a future issue, as the exhibition, though open, is not quite completed. For the moment it suffices to say that the French manufacturers of sanitary appliances have not been slow to profit by the ideas they were able to obtain at the London Health Exhibition; but, in some respects, they have taken the initiative, and English specialists will find several important improvements at the Sanitary Exhibition of the Caserne Lobau.

THE EMPLOYMENT OF EPILEPTICS.

WE have recently alluded to the need of providing for epileptics in institutions other than asylums organised for the insane. Another great and urgent need is to provide for the employment of epileptics, under conditions of safety, in such way that they may be able to support themselves, or, at least, to contribute towards their maintenance. This is a matter of very great interest and importance. A meeting of the Council of the Charity Organisation Society, at which this project was discussed, has just taken place, and among the speakers were members of our profession well qualified to speak with knowledge on the subject and to offer suggestions to the Council. We trust that the outcome of this and similar deliberations will soon be manifest in the shape of a formulated scheme, which the charitable may be able to help. The class of epileptics has been too commonly confounded with the lunatic population, and measures of special assistance consequently neglected or overlooked.

THE DALRYMPLE HOME FOR INEBRIATES.

THE Home at Rickmansworth seems an institution in which much good is being done, and much experience gathered that will be of use when a capable Legislature comes to deal adequately with the treatment of habitual drunkards. Of patients discharged since the opening of the Home, it is estimated that half have done well, and over 30 per cent. more have improved, so that between 75 and 80 per cent. have received decided benefit. The present Act is not only a poor instrument, requiring the consent of the patient, but it is actually deterrent by requiring that the patient shall appear before two justices. Accordingly more than half the admissions are not under the Act, but voluntary. The most flagrant cases and the great majority of habitual drunkards, of course, are never reached by the Act and are allowed by our absurd notions of freedom to ruin themselves, and too often all belonging to them. Of patients entering under the Act, 4 entered for twelve, 5 for six, and 3 for three months. Of private patients, 6 entered for twelve, 1 for nine, 6 for six, and 4 for three months. Patients show an increasing disposition to stay for

Digitized by Google

long periods. The element of heredity is made out with more clearness as the history of the disease is more closely studied. Of the 29 cases admitted, 12 had a family history of inebriety. Of the remaining 16, in which a history of inebriety could not be traced, in 2 there was a history of insanity, and in others of hysteria, neuralgia, and other neurotic affections; 3 were traceable to severe physical injury. Dr. R. Welsh Branthwaite publishes several tables of much interest. In one he gives us what he has been able to make out as to the exciting causes in 78 cases: Sociability, 28; nerve-shock, as from domestic, financial, or business trouble, 26; want of employment, 7; influence of occupation, 6; following injury, 3; not assigned, 8.

SURGICAL AFFECTIONS IN THE INSANE.

DR. GINÉ Y PARTAGAS, physician to the Barcelona Asylum, Nueva-Belén, in a clinical lecture published in *La Independencia Médica*, gives a *résumé* of the more important surgical maladies he has met with among lunatics. Erysipelas, he says, and especially erysipelas of the face, is very common, and should be watched for by the physician, as lunatics frequently do not trouble themselves about cutaneous affections. Eczema also is very common. As to furunculosis, he remarks that he has never seen it followed by cure or alleviation of the mental condition. The chief self-destructive propensity of melancholics seems to be to mutilate the genital organs. One man showed the doctor, as an evidence of his operative skill, a testicle which he had contrived to excise with the help of a piece of broken glass. Another patient managed with a similar implement to perform a true œsophagotomy. Dr. Giné remarks that it is wonderful how insensible they seem to the pain they thus inflict upon themselves. With regard to the difficulty of retaining splints on fractures, he says that for many years poroplastic appliances have been employed in Nueva-Belén with the most satisfactory results. In conclusion, he calls the attention of his hearers to the importance of careful examinations of the inguinal and crural regions of lunatics, who may have new herniæ or inflammations in old ones for some time without complaining.

THE MEDICAL COUNCIL AND THE BILL.

THE Medical Council shows signs of waking up. It is summoned to meet on Tuesday, June 1st, but it is possible that before its hibernation is quite over it may be superseded as a judge of foreign diplomas by the Privy Council, and that a Medical Bill may be passed which, under a show of leaving everything and everybody—including unqualified practitioners—very much as it finds them, may produce changes not contemplated by the authors and supporters of the Bill, and which will perpetuate the evils and inequalities justly complained of by the profession.

DIALYSING DIAPHRAGMS.

A PRACTICAL subject of much importance in the chemical laboratory is that of the relative permeability of various diaphragms; and the paper by Herr Zott in the *Annalen der Phys. und Chem.* will be therefore appreciated. Goldbeater's skin carries off the most useful, homogeneous, and water-tight material as a dialyser, and is twice as effectual under the same conditions as parchment-paper, which, on the authority of Graham, has hitherto been regarded as the best substance. When the solutions to be dialysed are of such a nature as to attack organic membranes, ordinary clay cells must be still employed, though they are sixty times less effectual than goldbeater's skin. It appears also that the rapidity of diffusion is increased by the complete exhaustion of the air contained within the pores of the dialyser; the rapidity is also dependent more on the increase of volume of the solution than on augmentation of the mass dissolved. After a preliminary exhaustion endosmosis takes place, even in the case of slowly diffusible substances such as colloids. The terms "colloid" and "crystalloid" are purely relative; two or more substances present in a solution are more rapidly and completely separated the greater the difference of their diffusion velocity. Separation by dialysis is more rapid the more often the liquid in the outer vessel is removed.

THE CHURCH OF ST. BARTHOLOMEW THE GREAT.

THOSE who have received their education at the great School of St. Bartholomew will probably be familiar with this ancient and interesting edifice, founded by Rahere (who was also founder of the hospital) in the year 1123, and which has endured nobly until now. The *Builder* of May 8th contains an excellent description of the church and of the proposed restoration of this magnificent relic of the architecture of the period; and a letter which appeared in the same journal of May 15th shows very cogently that the project has a singular claim upon the sympathy of the medical profession. The lawyers of the Temple possess their fine memorial church of the past; Lincoln's-inn is also similarly endowed. Why should not medicine be represented in its specially appropriate church of St. Bartholomew the Great? Its restoration would probably be costly, and funds would be needed, but the medical world of to-day will have reason to be proud if they render aid in this work of respect to their pious friend and benefactor of times gone by, Rahere. In this connexion we may refer to a little work by Normanus, beautifully illustrated by Mr. G. J. Evans, and which contains a minute description of the fine old Priory Church and its precincts. It is published by Mr. Barnes, Fore-street, City.

HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN SQUARE.

WE have received from the medical council of this hospital a statement made by them to the committee of management on certain differences that have lately arisen between these two bodies. In consequence of the action taken with regard to this statement by the lay committee, the medical staff, with the exception of one member, have sent in their resignations. From this *ex parte* statement it certainly appears that the lay committee have proceeded in an arbitrary manner in depriving the medical council of the voice they should have in the domestic medical affairs of the hospital. We shall probably have to recur to the matter.

COMPULSORY VACCINATION IN THE WORKHOUSE.

ON Saturday a woman made complaint to the magistrate at Hammersmith that her child had been vaccinated without her consent while an inmate of the Kensington Workhouse, and asked his opinion as to the legality of the action of the medical officer who had performed the operation. Mr. Bennett, in reply, stated that the mother's consent was unnecessary, as the vaccination had been done in compliance with an order of the Local Government Board. In an official circular of the year 1840, the Poor-law Commissioners expressed the opinion that the guardians have the right, without the permission of the parents, to vaccinate any child in their custody during any danger of contagion from small-pox; and the Poor-law Board again in 1848 pointed out that if the guardians and the workhouse medical officer think that any child in the workhouse requires vaccination, the medical officer should vaccinate such child, notwithstanding any objection on the part of the parents. The guardians are responsible for the safe custody and welfare of the child,

Digitized by Google

and are bound to take every precaution to prevent it from becoming the subject of infectious disease. This is only proper, and we should hope there are few persons who would raise any objection to the performance of an operation done so obviously in the interest of the child as well as in that of the general community.

DR. FOSTER'S AMENDMENTS TO THE BILL.

DR. FOSTER has put down on the paper several amendments intended to diminish the number of Crown representatives from six to four, and to give the difference to the profession—viz., to raise its representatives to four from two, an entirely inadequate number. We have advocated this change elsewhere, and before seeing Dr. Foster's amendments. Further, in any process of revision of the composition of the Council, Dr. Foster would provide that where any body ceases to be represented, in lieu of its representative one additional should be given to the practitioners in that division of the kingdom. The profession will be grateful to Dr. Foster for these amendments. We trust Sir Lyon Playfair will adopt them. Only in such ways can he justify to the profession a Bill leaving such numerous rival bodies, such an enlarged and costly Medical Council, and examining arrangements which will involve increased cost and complications to generations of medical men. Dr. Foster also wishes to pass an amendment to secure the registration of foreign degrees by those who, previously qualified, procured them after examination, and prior to the passing of the Bill. Subject to the approval of the Medical Council of the particular degree, we see no objection to this.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

THE festival of the Pharmaceutical Society is always one of the events of the season, and that of this week was no exception. The dinner, presided over by the President of the Society, M. Carteighe, Esq., was a great success, the company including representatives of all the scientific societies, from Professor G. G. Stokes, President of the Royal Society, downwards. Our own profession was strongly represented, and the mutually respectful feeling which has lately grown so much between medicine and pharmacy found happy expression in the speeches.

CIRCULATION OF BLOOD IN NERVOUS TISSUES.

THE large nervous ganglion cells are not extra-vascular; they do not lie in the meshes of a capillary network of bloodvessels. Each ganglion cell contains within its outer boundary a complete arterial and venous system; there is an intra-cellular vascular apparatus of most perfect description and arrangement. These are the conclusions of Adamkiewicz, already well known for his researches on the bloodvessels of the human spinal cord, and they may be studied in a thin volume under the title of "Der Blutkreislauf der Ganglionzelle" (Berlin, 1886, August Hirschwald). The nucleus we have for some time known is not a solid, but may be regarded as a cavernous organ; its caverns form a venous sinus which surrounds the nucleolus—so reports Adamkiewicz. From this central sinus a central vein leads the blood away and empties it into the vein of the neuroglia in its immediate vicinity. These assertions naturally strike one as extraordinary. The author in his preface cautions us not to be sceptical merely, but to search for ourselves or examine his own specimens. It is suggested that the nervous cells may have a direct influence on the circulation, aiding it or increasing its resistance, and that it may do this by the exercise of protoplasmic contractility or, we may presume, by more subtle processes. A description is given of the methods adopted in the ascertainment of the facts, the intra-cellular network of capillary vessels being demonstrated by injection of carmine and other fluids. Beautiful illustrations illuminate the text.

THE PASTEUR COMMISSION.

THE work of the Royal Commission appointed to inquire into Pasteur's method of inoculation for the prevention of hydrophobia consisted in the examination of groups of individuals who have been bitten by dogs, each group comprising all the cases that had been attacked by one dog. An endeavour was made to ascertain the nature and site of the wound inflicted, together with all attendant circumstances; also inquiry was directed as to the nature of the illness from which the suspected dog was suffering, or whether it were really ill at all. One day Dr. Sanderson and Mr. Horsley investigated a group of cases that occurred at St. Ouen. On another day Sir Henry Roscoe, Dr. L. Brunton, and the above named went to Brie, near Paris, and made a thorough inquiry into another series of cases. On the third day all the above-named members of the Commission, together with M. Chauveau, spent the morning with M. Pasteur, witnessing his inoculations on patients, and the afternoon was devoted to an inspection of the method of inoculation of the rabbits, which M. Pasteur demonstrated. On the fourth day Drs. Sanderson and Lauder Brunton worked out another group of cases in Paris, and Mr. V. Horsley spent the day at Pasteur's laboratory. The secretary to the Commission, Mr. Horsley, remained nearly another fortnight in Paris, and was engaged in collecting evidence concerning many cases of bites by alleged mad dogs in and around Paris, at Lyons, and St. Etienne. Altogether eighty-five cases were investigated in this indefatigable manner.

THE BIRMINGHAM SCHOOL.

AT a meeting of the Clinical Board of the General and Queen's Hospitals, Birmingham, held on the 14th inst., Sir James Sawyer resigned the presidency, after three years of office, and Mr. Oliver Pemberton, F.R.C.S., senior surgeon to the General Hospital, was elected to the presidential chair. The Birmingham School has steadily increased and prospered of late years, and the results have been highly creditable to professors and students. Sir James Sawyer's tenure of office has proved advantageous to the school in many ways. The arrangements for clinical teaching have been largely developed, and since the amalgamation of the two hospitals for clinical purposes the students have necessarily possessed facilities for study unsurpassed by those of any provincial school. The following resolution, proposed by Mr. Pemberton and seconded by Dr. A. H. Carter, was carried unanimously:—"That the cordial thanks of the members of the Birmingham Clinical Board be given to Sir James Sawyer M.D., for the unvarying courtesy, ability, and punctuality evinced by him as President during the past three years."

LARYNGEAL CORTICAL CENTRE.

CLOSELY associated with the interpretation of internal speech, the laryngeal muscles are most probably represented in close proximity to the posterior part of the third frontal convolution, especially of the left side of the brain. Krause has experimentally deprived dogs of the capacity to bark by destroying a certain point of the antero-external part of the gyrus præfrontalis of that animal. M. Garel adds his quota to existing knowledge in the *Revue Mensuelle de Laryngologie*, No. 5. He believes that the cortical laryngeal centre ought to be placed in the third frontal gyrus at the level of the foot of this convolution, and near the furrow that separates it from the ascending frontal.

THE INFLUENCE OF WATER ON NUTRITION.

THE necessity of a certain quantity of water for the assimilation of food and the chemical changes of the body which result in nutrition is admitted by everyone, but whether the ingestion of water in large quantities has an influence for increasing or decreasing metabolism has been called in question. In France the question has been studied. In that country the subject of obesity has a significance which it does not possess on this side the Channel, and it had been thought that the ingestion of large quantities of water had an important effect in reducing this abnormal bulk by rendering the oxidations more active, thus favouring the burning away of the fat which had been deposited by reason of the sluggishness of the nutritive changes. That this idea is not true has been shown by Dr. Debove. He has proved that the ingestion of large quantities of water has no influence on nutrition or body weight if care be taken that the solid diet is in no way altered at the same time. The determination of the urea showed the same fact. The observations were made on a friend who submitted to a strict diet of known weight, so that after a time his body weight remained stationary; the amount of water was then increased to more than double, and the daily amounts of urea, with the body weight, were tabulated, which showed at a glance the fact that water has no influence on nutrition, and that persons taking it in unusual quantities have no tendency to become thinner or fatter unless the solid constituents of the diet are lessened.

THE COUNTESS OF DUFFERIN'S FUND.

THE fund established by the Countess of Dufferin for the purpose of supplying female medical aid to the women of India continues to receive vigorous support from representatives of all classes and creeds in all parts of the Indian Empire. At a meeting recently held in connexion with the Burmah branch at Rangoon, amongst the speakers were the bishop of the city, two Burmans, a Chinaman, a Bengalee, and a Parsee. The social condition of a race of people can only improve when its women's domestic life and education are good; and as a movement in this direction the work of the National Association, under whose auspices the fund is administered, is one of very great value. Of all the philanthropic movements started by Europeans in India, none has so thoroughly enlisted the sympathies of the native population. The scheme deserves the support of all charitable persons, and should not be allowed to languish.

STERILITY DUE TO UTERINE DISPLACEMENTS.

IN a recent lecture M. Pajot says: "Another cause of sterility in women has often been, and still is, turned to profitable account by the quacks, and, unfortunately, also by doctors who prefer their own interests to those of science. This cause is uterine displacement..... Two years before the war I received a visit from an Austrian lady, who had an extreme retroflexion, for which she had consulted nearly all the doctors in the world, and they all, except Scanzoni, had told her that under the circumstances pregnancy was impossible. She menstruated regularly and painlessly. I told her that if the menses could pass out other things could pass in, and that her displacement was not a hopeless obstacle to conception. A week after I saw her she became pregnant, and was subsequently confined naturally, after which I kept her in bed till her menses reappeared (three months), and succeeded in producing a perfectly straight uterus, of which I was very proud. A year later the displacement was as bad as ever, but that did not prevent her from having two or three more children. This fact puts those who, with much ado, try to replace the uterus by special instruments, quite in the wrong. This is all useless; the best replacer of the uterus is pregnancy. A displacement cannot be considered as a disease; it is an infirmity, and moreover an infirmity easy to be borne. It is said that it causes grave inconveniences to women. For my part, I declare that if women had not been told by the doctor or midwife of their condition they would never suspect it, so little does it annoy them! It is only in cases of considerable descent, which weighs heavily and drags, that a displacement is a real inconvenience."

THE CHOLERA IN ITALY.

The news from Italy shows that cholera maintains itself steadily in the city of Venice and at Bari. In the seven days ending May 18th there had been 28 deaths from cholera in Venice, but the number of attacks was set down at only 37, which must necessarily be below the mark. At Bari 79 cases and 32 deaths are reported to have taken place during the same period. In the province of Brindisi the attacks, which never exceeded some 5 a day, gradually fell to a single one on the 14th inst., and since then no fresh attacks have occurred. There has thus been no increase of cholera in Venice and Bari, and elsewhere the disease has abated. This is, so far, satisfactory. But in view of the early season of the year it would be very premature to attach too much importance to any apparent diminution in the extent of the epidemic. Last year cholera prevailed off and on for several months in the Spanish province of Valencia before the sudden outburst early in June, which formed the commencement of a widespread epidemic throughout the peninsula. The failure of the disease to make rapid headway in Italy, whether it is owing to meteorological or other conditions, is, however, favourable to the carrying out of such sanitary measures as are known to hinder the spread of cholera; and in such action the best hopes for Italy now lie.

M. LOUIS MELSENS.

La Presse Médicale Belge says that Belgium has to deplore the loss of one of her most illustrious sons. M. Louis Melsens, who has just died at the age of seventy-two, was a distinguished chemist, his name being known not only in Belgium, but in all countries where there are scientific workers. He had a rare independence of character, and was a lover of science, to the advancement of which he contributed numerous researches. His paper on the Employment of Iodide of Potassium in Mercurial and Lead Poisoning has been of great service to public health, and was awarded prizes by the Institute of France and the Belgian Government.

OVERWORK AMONG FIREMEN.

IT is scandalous, because wholly irrational and the direct result of a pitiful policy of "economy"—falsely so called,—that our firemen are practically on duty without any complete remission twenty-four hours daily. To expect men, however courageous and devoted, to do their duty honourably and efficiently under such conditions of life is to expect more than human nature will continuously yield. With some personal knowledge of the working of the Brigade, we are bound to express the deep conviction that no body of public servants renders more uniformly good service; but it is surprising this should be so! The remedy is simple enough. Raise the rate for fire-protection purposes from a halfpenny to a penny in the pound *by all means*, but at the same time emancipate the Brigade from the government of the Metropolitan Board of Works. If the Metropolitan Fire Brigade were an independent organisation directly responsible to the Secretary of State, as the metropolitan police force is constituted, Captain Shaw would be able to provide London with a far more

Digitized by Google

efficient organisation. Let some member of the House of Commons ask for an exact return of the percentage which the Metropolitan Board of Works practically charges for managing the Fire Brigade business, and, unless we are greatly mistaken, there will be a revelation which must tend to place matters in an entirely new light.

MORTALITY AMONGST MEDICAL MEN DURING THE TYPHUS EPIDEMIC IN MOSCOW.

THE typhus epidemic in Moscow, which is now, it seems, on the wane, has played great havoc in the ranks of the profession, no less than five junior police surgeons having already died. Most of them were without private means, and have left their families entirely without provision. Five more surgeons have been attacked by the disease, and it is hoped that they may recover. The authorities have publicly thanked the police surgeons for their devotion to their trying and dangerous duties during the epidemic. It is to be desired, however, that the widows and orphans will be remembered in some better and more substantial manner than this.

THE MEDICAL BILL AND FOREIGN GRADUATES.

A PETITION in favour of admitting to the Register foreign degrees obtained by practitioners already registered after *bonâ fide* examinations has, we understand, been forwarded by the Foreign Graduates' Association to Dr. Balthazar Foster, M.P. for Chester, for presentation to the House of Commons. Communications have also passed between the Association and Sir Lyon Playfair upon the same subject.

HUGE DOSES OF BISMUTH IN CHOLERA.

AT the Madrid Academy of Medicine Señor Sanchez, of the Military Sanitary Service, described his method of treating cholera, which consists in the main in giving huge doses of subnitrate of bismuth—150 grains every half-hour or hour—until the diarrhœa is arrested. The oil of mustard is also employed externally, and a very rigorous diet enforced, even bouillon being excluded.

THOSE of the profession who make their autumnal holiday in Switzerland may be interested in knowing that on Aug. 11th the Société Médicale de la Suisse holds its congress at Geneva. In the same month other associations—the Société Helvétique des Sciences Naturelles, the Association Géographique, and the Société Géologique Suisse—will also meet in that city within a few days of each other.

El Siglo Medico is publishing a translation of Mr. Godlee's clinical lectures on the Surgical Treatment of Empyema; and a series of articles on the same subject, embodying the results observed in the Odessa Military Hospital, is at the present time appearing in the *Vrach* from the pen of Dr. A. T. Kazanli.

THE Aberdeen University Club met and dined in great force on Wednesday evening. About 120 members and guests were present. The guests included General Sir Donald Stewart, G.C.B., Sir Peter Lumsden, K.C.B., Colonel Duncan, M.P., and others. The chair was occupied by the Right Hon. Lord Watson.

ON the 11th inst., the death occurred, very suddenly, of Dr. M. Willett of Bristol. The deceased, who was seventy-two years of age, was well known to, and highly popular amongst, the inhabitants of the city, in which he had practised for many years.

THE death is announced of Dr. Karl Friederich Küttner, who was formerly Prosector to the Obuchow Hospital in St. Petersburg, but who for the last thirteen years had lived in Heidelberg, where he died from heart disease. He was a diligent and painstaking observer, making good use of the enormous amount of pathological material which passed through his hands at the Obuchow Hospital. His published works are mostly to be found in Virchow's *Archiv*. Amongst the more recent of these may be mentioned his papers on Epithelium of the Lungs and on the Circulation in the Lungs of Frogs and Mammalia.

AT the Royston Board of Guardians on the 12th inst., an outbreak of a severe epidemic of measles in several parishes was reported, and it was stated that four deaths had already occurred in one village.

PROFESSOR GAIRDNER has been chosen by the Glasgow Committee as President elect of the meeting of the British Medical Association to be held in Glasgow in 1888.

WE regret to hear that Professor von Arlt, the renowned Vienna ophthalmologist, has met with an accident. He fell in the street and fractured his left humerus.

Pharmacology and Therapeutics.

A SOLUTION OF COD-LIVER OIL IN MALT.

THE value as a therapeutic agent of an emulsion of cod-liver oil and extract of malt has long been recognised, but there are undoubtedly many cases in which patients are quite unable to assimilate such a preparation. Pharmacologists and practical physicians have long desired to obtain a true solution of cod-liver oil in malt, but the difficulties in the way of its accomplishment were found to be so great that all attempts to manufacture such a product were temporarily abandoned. The question has, however, at last been solved, and we have had submitted to us specimens which are undoubtedly true solutions of oil in malt. On examining an ordinary emulsion of cod-liver oil with even a low power of the microscope, it is seen to be made up of myriads of oil-globules, some small, but the majority of considerable size. On subjecting the solution of cod-liver oil in malt to examination, no globules of any kind can be detected with even the highest powers available. This new preparation, which is known as the Kepler Solution of Cod-liver Oil in Malt, differs but little in appearance from the old-fashioned emulsion of cod-liver oil in malt, but its superiority as a therapeutic agent, especially in cases of wasting disease, is obvious. Thanks to the spread of a knowledge of pharmacognosy, the time is fast coming when every medical man will systematically examine the drugs he prescribes, and will not be satisfied with mere random assertions as to their purity and value.

HYDRASTIN.

Dr. A. T. Slavatinski, who has published as a graduation dissertation an account of his researches on the pharmacological action of hydrastin, which he gave to a number of pregnant bitches and rabbits, as well as to other animals, finds that when introduced into the blood in doses of not less than a hundred-thousandth of the body weight, or one centigramme per kilogramme of the body weight, it acts as a stimulant to the spinal cord and medulla oblongata. In medium doses it paralyses the vaso-motor centres, thus decreasing the blood-pressure. It acts on the heart first as a stimulant, and afterwards as a depressant of the motor ganglia. No effect seems to be produced on the peripheral branches of the pneumogastric. The augmentation of the cardiac contractions begins from the spinal cord. At first

Digitized by Google

the secretory and convulsive centres are stimulated and afterwards paralysed. Hydrastin, in doses of from 0·01 to 0·03 grm. per kilogramme of body weight, was found to act as an ecbolic in pregnancy, and to produce contraction in the fibres of the non-pregnant uterus. At a certain period of pregnancy, which for the human subject is about seven months, the drug, in the same small doses (0·01 to 0·03 per kilogramme), if repeated a few times, appears to cause a miscarriage. The author had an opportunity of trying the ecbolic effect of hydrastin on a woman who had a contracted pelvis, and in whom it was desirable to bring on the labour somewhat before its proper time. On March 3rd, which was the commencement of the ninth month of pregnancy, a gramme dose of hydrochlorate of hydrastin was administered hypodermically morning and evening. These injections were repeated the following day. In the evening the patient noticed that the movements of the fœtus were particularly strong. On the forenoon of March 5th a gramme and a half was injected, and subsequently two strong movements were felt. The same evening two grammes were injected. On the forenoon of the 6th two grammes were given, and there followed during the day three strong movements. At night three grammes were injected. On the forenoon of the 7th three grammes were given, and one very violent and prolonged movement was experienced. Two grammes were given in the evening. No further injections were required, as signs of approaching labour manifested themselves. The child was born without complications, but it died the next day. Dr. Slavatinski suggests that if further experiments show that hydrastin may be used without danger to the mother, it may well replace the use of instruments in cases where premature induction of labour is required. He considers that hydrastin and its salts are more reliable than other preparations of the root. With regard to the dose for therapeutic purposes, he puts the maximum daily quantity at 0·3 grm. when given hypodermically, but would give doses of 0·5 grm. internally.

GRINDELIA ROBUSTA.

Grindelia robusta, which has been for some time in use in the form of the fluid extract, has recently been made the subject of a series of further elaborate investigations, both in the physiological laboratory and the hospital, by Dr. Dobroklonski, chief of Professor Botkin's clinic in St. Petersburg. (See THE LANCET of July 11th, 1885.) He made experiments on frogs, rabbits, and dogs to the number of sixty-eight, and gave the drug to patients suffering from various diseases. He found that the main effect, when moderate quantities were used, was to diminish the number of the heart beats, increasing at the same time the arterial tension. The effect on the heart appears to be due in warm-blooded animals to a stimulating action exercised on the inhibitory nervous apparatus of the heart, more particularly on that which is situated in the medulla oblongata. The increase of tension arises partly from a direct action of the drug, causing the vessels to contract, and partly from its stimulating action on the vaso-motor centres situated in the brain, the medulla, and the cord. Grindelia robusta also diminishes the irritability of the vaso-motor nerves of the heart and vessels, as well as that of the motor nerves and voluntary muscles, the nerves being more easily affected than the muscles, and the central more easily than the peripheral nerves. The therapeutic action of the drug, of which the author is in the habit of administering thirty drops three or four times daily, is, he believes, due to its power of decreasing and rendering more regular the cardiac contractions—having, he says, a greater regulating effect than digitalis, adonis vernalis, convallaria majalis, or chloral hydrate. It has, too, a diuretic action, but this is of less importance, being weaker than that of digitalis or adonis vernalis. He finds that grindelia robusta may advantageously be combined with adonis vernalis in cardiac diseases, which other more ordinarily used remedies have failed to relieve.

FLUORIDES OF AMMONIA AND IRON.

Dr. John Lucas of Bombay has employed the fluoride of ammonia in the treatment of hypertrophy of the spleen. The drug appears to have antipyretic and antiperiodic properties, as proved in cases of ague. Nausea was produced at first, but afterwards large doses could be borne. The appetite, after a time, improves under its use. By giving the drug after meals its nauseant and purgative actions are greatly lessened. "It certainly appears to possess the merit of excelling any other method of treatment of hypertrophied spleen with which we are acquainted." Dr. Lucas began with five-minim doses, but in future would be disposed to give twenty, or even thirty, minims well diluted. The fluoride of iron would, perhaps, be preferable to the ammonia salt, on account of its hæmatinic properties.

SUBCUTANEOUS INJECTIONS OF COCAINE IN ASTHMA.

Subcutaneous injections of a 5 per cent. solution of salicylate of cocaine are said by Mosler to arrest the paroxysms of asthma, and he believes that this remedy will prove useful in the general treatment of the affection. He gives 0·04 gramme (three-fifths of a grain) for a dose. In one case he remarked a certain amount of faintness, which, however, soon passed off. A Dresden physician, Dr. Beschorner, has also recorded favourable results from the use of cocaine in asthma.

LUNATIC ASYLUMS, 1885.

No. I.

EACH return of spring brings for us, with the primrose and the Lenten lily, its crop of annual blossoms in the form of reports, clad in every conceivable hue, from the various lunatic asylums of the country. These reports, not unlike the modest flower, tell us how much of homeliness and peace may be found in out-of-the-way places, and in places, too, sometimes so wild and darksome that they might seem almost to bid defiance to us in our most sanguine hopes. In themselves, however, these reports deal not with the poetry, but with the saddest and sternest realities, of our social and domestic life; they sum up, in general language and with an almost wearisome monotony of statistics, the annual events and transactions of our little worlds of unreason.

Taking the reports for the year 1885 now before us, it is our purpose, in the first place, to glance briefly at them one after the other, and to note what matters of special interest each one presents; and, in the second place, to give a general summary of the year's work in relation to the reports as a whole. With this view, we shall take it as a favour if the medical superintendents who have not sent to us a copy of their reports will kindly do so at their early convenience.

At the Cumberland and Westmoreland Asylum, the Superintendent (Dr. Campbell) says that the diminished admission-rate for the past year "fully bears out his formerly expressed views, that in this district extreme prosperity and high wages among the lower strata are a more powerful factor in causing insanity than the opposite extreme." Further, he bemoans and deprecates, on behalf of the private patients, the "mistaken kindness" of their relatives in pursuing the home treatment too long and delaying their admission into the asylum, so that "they do not at all have the same chance of recovery as their poorer fellow-sufferers." On the other hand, and on behalf of the ratepayers, Dr. Campbell calls attention to a matter of some importance—viz., the frequent readmission of persons suffering from insanity due to alcoholic excess. We take it that these persons are to be found at all stages of a scarcely varying chronological cycle, involving (1) drunken idleness ending in insanity; (2) admission to asylum; (3) speedy recovery; (4) early discharge from asylum; (5) rapid relapse. They would stand a much better chance (he says) of exemption from this self-brought-on insanity if after recovery in the asylum they were by law detained for an increasing period after each attack in some industrial institution, whose profits assisted to reduce the rates. We think the Prison Commissioners would have little difficulty in providing a few cells in their local habitations (on a modified penal scale, of course) for such "drowthy" and expensive misdemeanants.

There is a pleasing homeliness about the report of the Superintendent of the Dorset Asylum; and we regret that this experienced official should have to refer to himself as being in indifferent health. The Commissioners in Lunacy, however, in their report upon the asylum, call attention to the staff of attendants as being too weak; and this is not to be wondered at when we find 89 patients (of whom 11 are epileptics and 11 are in bed) under the care of four nurses and a supernumerary. We scarcely know whether the

Digitized by Google

nurses or the patients are most to be commiserated. Again, no wonder that Mr. Symes tells the Commissioners that he experiences great difficulty in getting nurses when the initial wages are £13, without uniform. The tone of a large asylum must always suffer when the authority and the element of self-respect which a quietly attractive uniform carries with it are lacking.

The report of the Devon Asylum, which, by the way, is to be commended for its excellent type and paper, is illustrated with most useful charts, which show at a glance the fluctuations in the annual population, death-rate, recoveries, and weekly cost *per caput*. Dr. Saunders still has his wards so overcrowded as to prevent him classifying his patients according to their mental requirements. Nevertheless, he has to report favourably as to the health of the community, and he says that the low rate of mortality (the percentage on the average number resident being 4·32; 3·21 on the males and 5·07 on the females) is remarkable, and without parallel in the history of the asylum. Dr. Saunders, also, has occasion to refer to a class of cases which merit the attention of the Prison Commissioners. "It is interesting to note how one or two patients of the 'rogue and vagabond' class were sent here and not found insane. They have sufficient craft and cunning, as they avow, to prefer the asylum to the gaol, and are usually persons who have no claims on the county, but are only casuals. From a review of past years it would appear that this class of patient is oftener met with than formerly. Malingering among our own insane poor is almost unknown." This statement is interesting not only with regard to the overcrowding of our asylums, but also with regard to the diminished numbers of our prison population.

The Superintendent of the Newcastle-upon-Tyne Asylum (Mr. Wickham) gives the following opinion on the relation between intemperance and insanity:—"It will probably be always a vexed question whether the intemperate habits are the cause of the insanity, or the insanity is the cause of the intemperate habits. As the result of many years' careful study of the causes of insanity, I can only remark that in the great majority of those particular cases which have come under my notice, the evidence is in favour of the conclusion that the insanity causes the intemperate habits. The reverse only happens when there is already some disease which is due to impaired nutrition. Perhaps it is for that reason that the descendants of a drunkard are more liable to insanity than the drunkard himself."

A good practical report of the working of a large institution is sent in by Mr. Barton, the Superintendent of the Surrey County Asylum at Brookwood. He is able to report a large percentage of recoveries on the number of admissions; and although the death-rate was somewhat higher than for the previous six years, it appears to have been due to the great number of feeble and broken-down cases admitted during the last two years. A commendable pathological zeal is observable at this asylum, for, with two exceptions, post-mortem examinations were made in all the 103 deaths that took place during the year. A criminal lunatic in an advanced stage of general paralysis was admitted. He had been sentenced to a month's hard labour for unlawful possession of a quantity of wood; and Mr. Barton says there is no doubt this man was not responsible for the act for which he was convicted, and which was simply the result of his disease. There is every reason to fear that this consignment of the insane to prison cells is of too frequent occurrence.

There is nothing special in the reports of the Superintendents of the Birmingham Borough Asylums, but the Lunacy Commissioners, in their report on the Winson-green Asylum, make the following remark:—"We saw in the hall at dinner 311 men and 221 women, who were seated, not, as is general in asylums, on different sides of the hall, but only on different sides of the tables. This arrangement seems here to be attended with very happy results, and the patients behaved with the greatest propriety."

The Superintendent of the East Riding Asylum at Beverley refers to the fact that the insanity of three only out of sixty-two admissions during the year was due to intemperance. He fears that this small proportion of cases due to intemperance is "but a sign of hard times." "One patient, an idiot, died of premature decay at the age of twenty-two. His development had been arrested in early life. He could neither see, hear, nor speak; he could not even stand; his existence was a mere fact, and not equal to that of a healthy plant."

BURGH POLICE AND HEALTH (SCOTLAND) BILL.

THE Burgh Police and Health Bill for Scotland, one of the measures introduced last year into Parliament, but abandoned at the end of the session, has passed the House of Lords and now awaits the consideration of the Commons. In addition to the regulations necessary for the constitution of police burghs and the formation and maintenance of a police force, there is much in the Bill bearing upon the sanitary condition of the towns and of the houses, and also an important section on the mitigation and prevention of disease. To some of the proposed clauses we think it necessary to draw the attention of the profession. The 66th clause enacts that the commissioners appointed for the purposes of the Act, elected by ballot by the householders of the burgh, and one-third of whom retire annually, "shall appoint annually a legally qualified medical practitioner, who shall be styled the 'medical officer of health,' and whose duty it shall be to ascertain the existence of disease within the limits appointed to him, especially of all infectious diseases, and to point out any local causes likely to occasion or continue such diseases or otherwise injure the health of the inhabitants," &c. The tenure of office of the medical officer of health for one year only, or the necessity of his reappointment annually by a fluctuating body of commissioners, appears to be very objectionable, as likely to interfere with his independent action—in such cases, for instance, as those in which some of the more influential commissioners may be the owners of property which, from its insanitary condition, should be reported as injurious to the health of the occupants. The interests alike of the public and of the profession seem to us to require that the appointment should be permanent, subject only to being cancelled for inefficiency or neglect on the part of the holder, such dismissal to require the approval of the Board of Supervision. Under Clause 325, with a view to secure the notification of cases of infectious disease, it is provided that "every medical practitioner resident or practising within the burgh shall, within twenty-four hours of the same coming to his knowledge, report to the medical officer of health every case of infectious disease and whooping-cough occurring in his practice, and stating the building or ship where the patient is being treated, under a penalty of forty shillings; and if it be found that the diagnosis of such practitioner was correct such practitioner shall be paid the sum of two shillings and sixpence for each case reported and verified as aforesaid." It is not said by whom this verification is to be made, but we presume it is by the medical officer of health. To this we see very serious objection, especially in those instances in which he is also a practitioner in the borough. It cannot fail to give rise on some occasions to very unpleasant feelings, and it seems quite unnecessary. The certificate of a duly qualified practitioner ought to be accepted as sufficient evidence of the nature of the case. When no medical practitioner has been called in, the occupier or person in charge of the building is to give notice to the medical officer of health of any case of infectious disease of the existence of which he shall become aware; but no remuneration is provided for so doing, nor is there any penalty for neglecting to report it. The commissioners are bound to intimate any outbreak of infectious disease within the burgh to the Board of Supervision, who must notify it to contiguous local authorities under the Public Health Acts. Under the term "infectious disease" are comprehended "cholera, smallpox, typhus, typhoid, scarlet, relapsing, continued, and puerperal fever, measles, scarlatina, and diphtheria, and such other disease as the commissioners, with the approval of the Board of Supervision, or Her Majesty by Order in Council, may, from time to time declare, for the purposes of this Act, to be infectious." Why scarlet fever and scarlatina should be classed separately, and why whooping-cough should be excluded from the list of infectious diseases, are mysteries known only to the Parliamentary draughtsman.

The commissioners are to provide in or near the burgh a hospital for the treatment of infectious diseases, which must be licensed by the magistrates before being occupied, on the certificate of the medical officer of health or some other duly qualified medical practitioner that it is suitable for such purpose, the licence to be renewed annually; also a reception-house for persons removed from an infected house, but who are not suffering from disease themselves,

Digitized by Google

and a disinfecting-house with necessary apparatus; and they may provide nurses for attendance upon infectious cases. The medical officer of health is to have power, in cases where from insufficient accommodation he has reason to fear the spread of infectious disease, to remove the patient to hospital, the expense incurred to be defrayed out of the burgh general assessment. The commissioners are to be empowered to remove to the reception-house for a period not exceeding fourteen days all the residents of an infected house, on the production of a certificate signed by the medical officer that such removal is necessary to avoid the spread of disease, and to prevent the return of any of the residents until the house and all the bed and body clothing have been cleansed and disinfected to the satisfaction of the medical officer. If the commissioners are of opinion "on the certificate of their medical officer of health, or of any other legally qualified practitioner," that this cleansing and disinfection would be more effectually carried out by their own staff than by the owner or occupier of the house, they may cause it to be done, but at their own cost, and making compensation for any property or articles destroyed or injured. A penalty not exceeding forty shillings is to be inflicted on any person getting rid of the excreta of patients suffering from infectious disease, or of any article likely to communicate it or to retain infection, without previously disinfecting them. Mortuaries and proper carriages for the removal of the bodies to them are to be provided, and a heavy penalty is to be inflicted on anyone retaining unburied for longer than forty-eight hours, except in a mortuary, or with the sanction in writing of the medical officer of health or of a registered medical practitioner, the body of any person who has died of infectious disease. Wakes are likewise forbidden in such cases. The Bill also provides for the prevention of children who have suffered from infectious disease, or are resident in a house where such exists, attending school until free from disease and infection and the house and its contents have been disinfected to the satisfaction of the medical officer of health. Occupiers of milk-shops and dairies are to give notice of any persons employed in them being attacked with infectious diseases. When there is reason to believe that the spread of such disease is attributable to milk, the commissioners are to have power to require the cowkeeper, purveyor, or occupier of a dairy or milk-shop to furnish lists of the customers supplied by them, which will afford most important means of tracing its influence, and verifying or removing the suspicion. On the certificate of the medical officer of health that, in his opinion, an infectious disease is being spread by the sale or delivery of milk from any dairy or farm, the Procurator Fiscal or sanitary inspector "shall apply to the magistrate for an order to prohibit the sale of the milk so brought, from and after due intimation of such order, until the person affected has been removed or has recovered from such illness, the premises been disinfected, and the bedding and clothing have been destroyed or thoroughly disinfected, and until it is certified by the medical officer of health that the said premises are free from infection and in a proper sanitary condition, and that the sale of milk from such place may be resumed."

THE LATE SURGEON-MAJOR T. R. LEWIS, M.B.,

ASSISTANT PROFESSOR OF PATHOLOGY, NETLEY.

THE premature death of Surgeon-Major Timothy R. Lewis, M.B., is a loss not circumscribed within the limits of the department to which he belonged, for it is a severe loss to the profession and the cause of science generally. There is something peculiarly pathetic in his death at a time when he had been elected for the blue ribbon of science, but did not live to have the honour of the F.R.S. actually conferred upon him. There is very little doubt, too, that his death was attributable to his scientific ardour, for his attack of fatal pneumonia seems to have developed out of some septic poisoning following a dissection wound.

The deceased possessed a rare combination of qualities: keen love of work, patient industry, penetration, a strong and impartial judgment, a well-trained eye and hand, linguistic knowledge, and a very modest and amiable character. His ability and aptitude for scientific inquiries early attracted attention at Netley, and, in connexion with Dr. D. D. Cunningham, he was selected, at the suggestion of the late Professor Parkes, to conduct a special scientific investigation into the theory of the fungoid origin of cholera advanced more particularly by Professor Hallier of Jena, and that of the connexion existing between this disease and certain conditions of soil promulgated by Professor M. von. Pettenkofer of Munich. After a special course of study in Europe, Cunningham and Lewis went to India, and published, in connexion with the sanitary department of that country, a series of very exhaustive observations on these subjects—microscopical, chemical, experimental, and otherwise. Lewis did a great deal of work with the Sanitary Commissioner of the Government of India (Surgeon-General Cuningham), largely aiding that official in the preparation of his reports, and contributing also from time to time special papers to those reports, either by himself or in connexion with his colleague, Dr. D. D. Cunningham.

To complete what we have to say of Lewis's labours in relation to cholera brings us down to the present time, and to investigations still incomplete. As is well known, a German Commission, under the distinguished *savant*, Dr. Robt. Koch, was sent to Egypt to study the subject of cholera during the late epidemic in that country; and subsequently the Commission proceeded to India to complete the series of observations necessary for establishing the identity of the disease in Egypt with Indian cholera. It is not necessary to discuss in detail the results of those investigations; the outcome of them was, in the opinion of the Commission and others, to establish that the so-called comma-shaped bacillus was invariably present in, and the cause of, cholera. Lewis, who by this time had left India, and was Assistant Professor of Pathology, Army Medical School, Netley, with the zeal that characterised him, started off to Marseilles and Toulon, to corroborate for himself this alleged discovery. In September, 1884, he published a memorandum on the subject, in which he demonstrated that a comma bacillus microscopically identical with Koch's was present in the saliva, and he criticised with great penetration the views advanced by the German micro-pathologist. The Indian Government subsequently sent out a Commission to India (that of Drs. E. Klein and Heneage Gibbes), and their report was submitted for the decision of a committee convened in 1885 by the Secretary of State for India under the presidency of Sir Wm. Jenner, of which committee Lewis was appointed honorary secretary. Lewis contributed to their report the results of some very valuable and original observations in further pursuit of a subject, the investigation of which he was probably better qualified to undertake than anyone living. The latest report—21st Annual Report of the Sanitary Commissioner of the Government of India, published in 1886—corroborates the correctness of Lewis's views; and, as matters at present stand, Koch's alleged discovery is at present not proven.

At the late Sanitary Conference at Rome Lewis was one of the delegates, and did excellent service to the cause of science and scientific sanitary legislation. But it was in his parasitological researches in endemic hæmaturia and chyluria in the discovery of the filaria sanguinis hominis that Lewis performed his more brilliant and original work. The subject is one of great importance, and in its latest advances in relation to the life history of filaria, the mosquito its intermediate host, and the periodicity of the phenomena, it forms a study of extreme interest in micro-pathology and natural history. Lewis made the discovery of the filaria in the urine of patients in the General Hospital, Calcutta, in 1869. In 1871 the same filaria was discovered by him in the blood, and several specimens were forwarded to the late Professor Parkes in this country. The blood is infested with a living worm about $\frac{1}{3}$th of an inch in length and $\frac{1}{5\,0\,0}$th of an inch in diameter. Upon the subsequent researches of Dr. Manson in China and Dr. Bancroft in Australia there is no need to dwell. The whole question is discussed in the new volume (vol. ii.) of Hirsch's Handbook of Geographical and Historical Pathology, published by the New Sydenham Society. It is not, we think, very creditable to the Government of this country or that of India that Lewis received no State recognition of his important services. Science counts for very little compared with the glamour of the profession of arms.

ON the 16th inst. the Hospital Sunday collections were made at Birkenhead.

THE UNIVERSITY OF LONDON.

Scheme embodying the Resolutions of the Special Committee for the consideration of the Scheme for the Constitution of the University.

SECTION 1. *University.*—The University to consist of: (*a*) Senate; (*b*) Convocation; (*c*) Constituent Colleges; (*d*) Council of Education [in place of Faculties and Boards of Studies].

SECTION 2. *Senate.*—The Senate to consist of: (*a*) Chancellor to be appointed by the Crown. (*b*) Vice-Chancellor to be elected by the Senate annually from amongst its members. (*c*) The following members *ex-officio:* chairman of Convocation, chairman of Council of Education,* and chairman of each of the four Boards of Studies.* (*d*) Ordinary members to be appointed as follows: Six by the Crown, eight by Convocation [instead of six], four by the Council of Education,* and one by each of the seven following institutions—University College, King's College, Royal Society [additional], Royal College of Physicians of London, Royal College of Surgeons of England, Council of Legal Education, and Council of Incorporated Law Society. The ordinary members to hold office for a period of four years, and to be re-eligible. The Senators elected by Convocation to be elected by members of Convocation voting in their respective Faculties. Two members to be elected by the members of each of the four Faculties. The Senate to have the control and management of the University.

SECTION 3. *Convocation.*—Convocation to remain constituted as at present, with such increased powers as are herein referred to.

SECTION 4. *Constituent Colleges.*—The constituent colleges to consist of educational bodies in or near London, together with other institutions or colleges not affiliated as constituent colleges to any other University, and having one or more Faculties of university rank; and to be (*a*) such bodies as may be named in a schedule to be settled by a joint committee of the Senate and Convocation; (*b*) such other bodies as may be hereafter admitted by the Senate with the concurrence of a joint committee of Convocation and the Council of Education. On the admission of each constituent college, it shall be determined to what Faculty or Faculties it shall belong, and in what mode it shall be represented on the Council of Education, and such terms may be subsequently revised by the Senate, with the concurrence of a joint committee of Convocation and the Council of Education. The Senate to have power, with the like concurrence, for good cause to remove any college from being a constituent college. The institutions from which the University receives certificates for degrees in Medicine to retain their right of giving such certificates, whether they be constituent colleges or not; the list of such institutions to be subject to the existing power of revision; but the Senate not to report thereon without the like concurrence.

SECTION 5. *Council of Education.*—The Council of Education to consist of: (*a*) representatives of Convocation; (*b*) representatives of the constituent colleges; (*c*) the examiners of the University. The representatives of Convocation to be members of Convocation, and to be elected by the members of Convocation voting in their respective Faculties. Convocation to elect one-fourth of the total number of the members of Council. The representatives of constituent colleges to be professors or persons engaged in giving instruction of university rank. The representatives of Convocation on the Council of Education to hold office for a period of four years, and to be re-eligible. The Council of Education to advise the Senate on all matters connected with the subjects of examination and the teaching thereof. The Council of Education to appoint a chairman annually. The Council of Education to appoint from among its members standing committees or Boards of Studies, one in each of the four Faculties, and also to have power to appoint special committees as it sees fit. Each board to appoint a chairman annually. Each Board of Studies to consider matters connected with its own Faculty and to report theron to the Council of Education.

SECTION 6. *Provisions for Promotion of Higher Education.*—The University to have power to hold real property and to accept gifts, devises, and legacies for the purposes of the University. The Senate to take steps to secure to the University a fixed endowment from the State in lieu of the present annual grant, with power of exclusive control over its application and expenditure. The Senate to have power to appoint professors, lecturers, and examiners in any branch of knowledge; to subsidise or endow laboratories, libraries, and museums; to make grants out of the funds of the University for the purpose of research; and to assist by any other means in promoting higher education. The Senate to have power to confer honorary degrees.

SECTION 7. *Supplementary Provisions.*—The existing members of the Senate to continue. The Crown not to appoint any new members until the number of the present Crown nominees is reduced to five, and then to nominate from time to time to vacancies occurring in any of its six places. Convocation at once to elect one moiety of its complement of members to the Senate and to the Council of Education respectively, and at the end of two years to elect the other moiety, and each Faculty to fill up from time to time vacancies occurring in the number of its representatives. The Council of Education, when constituted, to elect its complement of members to the Senate, two of whom, to be determined by ballot, shall retire at the end of two years; and the Council of Education to fill up from time to time vacancies occurring in the number of its representatives. All elections by Convocation under this scheme to be by voting papers.

* Instead of three by each of the four Faculties.

EXTRAORDINARY CÆSAREAN OPERATION.

OUR recent annotation under this heading (THE LANCET, May 8th, p. 890) was based on such an exceptional series of facts, that with the fullest confidence in the authority from which we quoted—*La Gazzetta degli Ospitali*,—we sought fuller information from the patient's medical attendants, Drs. Raniero Baliva and Adolfo Serpieri. Those gentlemen have our warm thanks for their courteously prompt and full reply, which we translate:—

"Viterbo, 15th May, 1886.

"We append a summary history of the Cæsarean section which N—— de A—— of Viterbo practised upon herself on the morning of the 28th March last.

"A peasant woman of Viterbo, aged twenty-three, of lymphatic temperature short stature (one metre and forty cent.), and of delicate constitution, was in the last month of pregnancy. As her condition was talked about amongst her neighbours, and provoked the anger of members of her family and of her masters, she came to the following unheard-of determination. At 3 A.M. on the 28th of March, as she relates, with a not very sharp kitchen knife she opened her abdomen. The wound was linear, but somewhat jagged (*efrangiata*), twelve centimetres in length, situated in the middle of the right iliac region, from a little above the level of the umbilicus downwards, and from without inwards. She penetrated with a somewhat less extensive incision into the uterus, and extracted from it a male fœtus at the ninth month, weighing 1 kilogramme and 900 grammes. This fœtus, before being extracted from the uterus, had received several important wounds in the thorax and abdomen, whereof it died before breathing, as was undoubtedly proved by the results of the necroscopic analysis. The head had been divided from the trunk by a circular incision at the base of the neck and precisely between the penultimate and the last cervical vertebra. The cord was detached from the placenta and the fœtus. The placenta was perfectly healthy. This operation completed, the patient states that she tightly bound a bandage round her body, so as to bring the edges of the wound together and prevent the protrusion of the intestinal coils; then, having dressed herself at 5 A.M., two hours after the operation, she went into Viterbo on foot, a distance of one kilometre, and visited a married sister, to whom she said nothing of what had happened, but breakfasted with her on bread and coffee and a cup of broth. She then left the house and walked about the town for some time, in order, as she states, to show herself and to put an end to the current talk about her pregnancy. At 10 o'clock, still on

Digitized by Google

foot, she returned to her home in the country; on reaching it she was seized with unbearable abdominal pains, followed by violent vomiting and fainting. She quickly rallied, and, the bandage having slipped upwards, almost the whole of the small intestines protruded. It was only then (about 11 o'clock) that the father, mother, and brother became aware of the serious occurrence, and went to Viterbo for medical assistance.

"We were the first to arrive on the spot at 4 P.M., the same day, thirteen hours after the incision, and six hours after the escape of the intestines. We found the patient in pain, but not so much so as might have been anticipated from the gravity of the case; she was conscious and tolerably calm. She was lying dressed on a small bed in a well-ventilated room. Without loss of time, with all possible precautions, and with the limited means at our disposal in the country, we proceeded to cleanse the intestines and to replace them in the abdominal cavity, after having emptied it of copious sero-sanguineous effusion. We were scrupulously careful to secure the utmost possible cleanliness; the wound was closed with twisted sutures, and a drainage-tube placed in its most dependent part. Strict injunctions for necessary care were given to the patient and her attendant. During the first five days no serious change occurred. The thermometer never rose beyond 39·5° C. There was no sign of uterine disturbance; the peritonitis was only partial; thirst slight; vomiting at night. During the first three days micturition was difficult and the bowels inactive. The catheter was only passed once, on the third day, from which period the bowels acted copiously and regularly. The patient slept for several hours on the previous night; her sufferings were not great, and on the eighth day her recovery seemed assured. At the commencement abundant bloody serum and badly-smelling clots escaped from the turgid and painful abdomen. A considerable quantity of omentum protruded. Pus followed, thin at first, but became thick on the tenth day, and then gradually decreased in quantity. The discharge all took place through the lower angle of the wound, the deep parts of which healed by first intention for about two-thirds of its extent. On the twenty-fifth day the wound was purely superficial, and limited to six centimetres in length. Cicatrisation was complete on the fortieth day. The patient is now (forty-eighth day) perfectly well and walks about. She is under the surveillance of the judicial authority and is receiving much sympathy from the public.

"The occurrence, though seemingly incredible, is perfectly true. We have related the actual facts, accepting the patient's statement that she operated upon herself. What is even more extraordinary than the operation is recovery in the proved circumstances of the actual case. We shall be happy to supply any further information desired.

"RANIERO BALIVA, M.D.
ADOLFO SERPIERI, M.D.

"P.S. Externally we made use of a solution of carbolic acid 4 per cent., and of 1 per cent. for injection through the drainage-tube, which was removed the tenth day as it appeared to irritate. The sutures were removed the fourteenth day. During the first fifteen days the dressings were changed four times daily. At first abstinence from food was strict; after a few days good wine was allowed. Throughout the treatment preparations of quinine were administered. Only two oil purgatives were given in the early days. Ice was freely used during the first five days to counteract hiccough and vomiting. Until recovery was complete the woman was covered with carbolised cotton wool."

UNIVERSITY COLLEGE HOSPITAL.—The Executive Committee have arranged for a fancy dress ball to be held at Willis's Rooms, King-street, St. James's, on Tuesday, June 1st, 1886, in aid of the funds of the above hospital. The bazaar, to be held in the grounds of University College, will be opened by the Princess Louise on July 2nd—not the 9th, as stated in our last.

THE NEW MEDICAL BILL: SUGGESTIONS.

"M.D." suggests: 1. After —— no one shall be allowed to practise medicine or surgery in the United Kingdom without first obtaining a Government permit and a title from one of the present recognised licensing bodies under a penalty of - — &c. 2. The Government permit to be granted (*a*) after a conjoint examination in medicine and surgery under conditions as approved of by the Medical Council, at a fee of ——; (*b*) on application, free of charge, to all whose names appear on the Medical Register, or who possessed registerable qualifications at the date of the Bill becoming law. The Government permit would ensure that all candidates passed the same standard of examination, and, a title being required as a licence to practise, the present licensing bodies would not be interfered with—a rock on which all proposed Medical Bills have come to grief.

With reference to health diplomas, the Association of Medical Practitioners qualified in Sanitary Science suggest the following clause: "All registered medical practitioners who have obtained from any university or medical corporation of the United Kingdom a qualification in Public Health after examination shall be permitted, and are hereby empowered, to register the same as a qualification under the Medical Act on payment of such fee as the Council may appoint." We understand that Sir H. Holland has consented to move the above clause as an amendment in committee.

With regard to foreign degrees, "A Medical Man with British Diplomas" thinks it is a great mistake, in face of the increased number of medical men who are yearly admitted on the Register, to propose that foreign diplomas shall be registered, especially considering how easily these foreign diplomas are obtained. He thinks that in the background there must be some motive for legalising these diplomas, as it cannot be for the good of the profession.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Diphtheria at the Royal Female Orphan Asylum, by Dr. GRESSWELL.—The fact of a prevalence of diphtheria in this institution having occurred in November last, with its reappearance in January, and the circumstance that the cause had "baffled all inquiries," led to the investigation which Dr. Gresswell made on behalf of the Local Government Board. The institution contains, with its resident staff and the orphan girls, 151 persons; and it is located on a piece of low-lying ground completely encircled by the river Wandle, or by a conduit, partly covered and partly open, which connected together a semicircular sweep of the river. The site itself is thus unpromising. Then, again, for many years past cesspool drainage had been resorted to, and when this was abandoned, after an epidemic of enteric fever, an ill-devised sewer, which can only now be described as constituting an elongated cesspool, took its place; some of the old house drains and soil-pipes being so left or disposed of that little else is known of them than that foul odours tend to prevail, and that in connexion with some of these nuisances one old soil-pipe was discovered and removed. Such conditions, superadded to the character of the site, become most unfavourable when associated with diphtheria. Then, again, the building forming the asylum is so constructed that the infirmary, wards, bedrooms, &c., all have one common air, and hence no proper isolation, in the sense of aerial severance of sick from healthy, can be expected. Under these circumstances, Dr. Gresswell looked into the previous sanitary history of the inmates, and he records a long list of ailments since 1867, which include sore-throats, diphtheria, diarrhœa, ophthalmia, erysipelas, gastric fever and irritations, enteric fever, &c., which go to show that for a very long period diphtheria in its more or less marked forms, and many other diseases which are known to be associated with conditions leading to the pollution of the air, have prevailed in the institution.

Digitized by Google

So also Dr. Gresswell, dealing essentially with the throat mischief, which he especially inquired into, finds in the meagre sickness returns of the establishment a large number of entries of sore-throat, putrid throat, strumous throat, and the like, together with ailments suggestive of diphtheritic sequelæ; and on examining the throats of the orphan girls, he says that "hardly more than one-third can be spoken of as possessed of healthy tonsils." The remainder "have tonsils which are enlarged, many hugely so ....., and now and again they present evidence of follicular inflammation." How, under these circumstances, the cause of diphtheria can have baffled even the most superficial inquiry is astounding. In almost all the details of its sanitary history, this institution presents some of the most essential characteristics of places to which diphtheria is known to cling with exceptional tenacity, and the disease has, more or less masked or self-evident in type, been long prevalent there. Locally, we learn, there has been a suggestion that the proximity of the Croydon sewage farm, which lies almost immediately to the north and east on the opposite side of the Wandle, has been the cause of this chronic state of illness amongst the inmates; but, as Dr. Gresswell very properly says, until the sanitary condition of the institution itself has been put upon a proper footing, any attempt at differentiation of possible causes of the chronic illnesses in persons living therein would certainly be futile. We have no wish to exonerate the sewage farm. On the contrary, the influence of sewage farms on public health is one of the subjects concerning which accurate and trustworthy information is much needed. But there are other populations near to the Croydon farm, and, so far as we know, they have not suffered in the same way as this institution has; whereas on their own premises the governing body of the asylum will find in abundance the very conditions which, if they do not continually cause initial cases of diphtheria, ensure its persistent prevalence when once the disease has been introduced.

Diphtheria in the Rural District of Walsingham, by Dr. GRESSWELL.—Walsingham registration district was one of the districts which suffered from diphtheria during the great epidemic which commenced in 1858. During that year the fatal cases were only 3 in number, but they steadily rose year by year to 27 in 1862, and then ensued a diminution, marked, however, by a temporary increase again in 1873. But it is to be noted that ever since 1858 deaths have, with the exception of one single year, been every twelve months ascribed to diphtheria, and even in that year, as in nearly all the others, fatal attacks of throat diseases, which we have now come to regard as at least allied with diphtheria, occurred. The investigation carried out did not lead to any new information as to the etiology of this obscure disease, and this was necessarily the case because so many general insanitary conditions prevail there that, until these are eliminated one by one, in so far as cause is concerned, it is impossible to ascribe the disease to any definite condition. Mr. Power inspected two of the parishes in this district in 1875, and he then found diphtheria to prevail in connexion with a want of proper sewerage and drainage, a scarcity of drinking-water in dry seasons, and insufficiently ventilated dwellings. It is difficult to see that there has been even a semblance of improvement since that date, for even at Fakenham, which is the market town and has a considerable population, the cottages were found to be damp and ill-ventilated. Foul cesspools exist which ventilate into the houses through untrapped sink-pipes and ill-ventilated soil-pipes; and privy vaults, ash-pits, and filth accumulations lie in the immediate neighbourhood of houses and wells. A district thus circumstanced can hardly be expected to get rid of a disease like diphtheria, and the various details given in Dr. Gresswell's report go far to show how seriously they must necessarily affect public health in the district. To one point especial prominence is given—namely, the damp condition of the dwellings—a condition with which diphtheria has again and again been found to be associated. Thus, at Stiffkey a large number of houses are built into the hillside without protection from the wet of the higher land above, the back walls being, in consequence, damp and covered with various moulds. The floors of the lower rooms are generally below the level of the ground outside, which is both unpaved and undrained; and this condition of dampness is aggravated by the absence of eaves-spouting, which, together with a dilapidated state of the roofs, ensure dampness of the upper as well as of the lower rooms. Under such circumstances, the Walsingham registration district again in 1884 suffered from a diphtheria epidemic, which caused 21 deaths, in addition to 8 more from other throat affections, and the disease extended well into 1885. Indeed, according to the Registrar-General's quarterly returns, no less than 12 diphtheria deaths are recorded during the four quarters of 1885 for the registration district. With the exception of the parish of Wells-next-the-Sea, the district is under the administration of the rural sanitary authority, and their attention may well be called to the state of the area under their jurisdiction with regard to the removable causes of disease which have so long prevailed in it.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5273 births and 3321 deaths were registered during the week ending May 15th. The annual death-rate in these towns, which had been equal to 19·8, 20·2, and 20·6 per 1000 in the preceding three weeks, declined last week to 19·1, and was lower than that recorded in any week since October, 1885. During the first six weeks of the current quarter the death-rate in these towns averaged 20·0 per 1000, and was 3·2 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 8·8 in Huddersfield, 10·4 in Birkenhead, 14·2 in Derby, and 16·0 in Sunderland. The rates in the other towns ranged upwards to 24·1 in Blackburn, 24·3 in Hull, 27·8 in Preston, and 28·2 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 382, 364, and 367 in the preceding three weeks, further declined last week to 324, a considerably lower number than in any recent week; they included 120 from whooping-cough, 90 from measles, 39 from diarrhœa, 30 from diphtheria, 23 from scarlet fever, 21 from "fever" (principally enteric), and 1 from small-pox. No death from any of these zymotic diseases was recorded last week in Huddersfield, whereas they caused the highest death-rates in Blackburn, Portsmouth, and Bolton. The greatest mortality from whooping-cough occurred in Salford and Bolton; from measles in Preston, Portsmouth, and Bolton. The 30 deaths from diphtheria in the twenty-eight towns included 19 in London, 3 in Liverpool, and 2 in Portsmouth. Small-pox caused 3 deaths among the residents of London and its outer ring, 1 in Blackburn, and not one in any of the twenty-six other large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had slowly increased in the previous seven weeks from 7 to 27, had further risen to 30 on Saturday last; 9 cases were admitted to these hospitals during the week, against 3 and 11 in the preceding two weeks. The Highgate Small-pox Hospital contained 4 patients on Saturday last, 2 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 296 and 309 in the previous two weeks, declined last week to 293, and were 49 below the corrected average. The causes of 83, or 2·5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Norwich, Derby, and Wolverhampton. The largest proportions of uncertified deaths were registered in Halifax, Bristol, Bolton, and Plymouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·1 and 22·3 per 1000 in the preceding two weeks, was 22·2 in the week ending May 15th, and exceeded by 3·1 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 8·2 and 12·5 in Perth and Greenock, to 23·7 and 27·6 in Leith and Glasgow. The 548 deaths in the eight towns almost corresponded with the number in the preceding week, and included 17 which were referred to measles, 14 to whooping-cough, 13 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 3 to scarlet fever, and not one to small-pox; in all, 55 deaths resulted from these principal zymotic diseases, against 51 and 62 in the preceding two weeks. These 55 deaths were equal to an annual rate of 2·2 per 1000, which exceeded the mean rate from the same diseases in the twenty-eight

Digitized by Google

English towns. The fatal cases of measles, which had been 15 and 17 in the previous two weeks, were last week again 17, of which 12 occurred in Edinburgh and 4 in Leith. The 14 deaths from whooping-cough showed a further decline from the numbers returned in the preceding two weeks and included 12 in Glasgow. The 13 fatal cases of diarrhœa showed a further increase upon recent weekly numbers; 6 occurred in Glasgow and 4 in Paisley. The deaths referred to different forms of fever, which had been 2 in each of the preceding two weeks, rose to 5, and included 2 in Edinburgh and 2 in Leith. Of the 3 fatal cases of diphtheria 2 occurred in Glasgow. The deaths from scarlet fever, which had increased from 3 to 8 in the previous three weeks, declined again to 3, all of which were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 128 and 111 in the preceding two weeks, further declined last week to 108, which, however, exceeded by 10 the number in the corresponding week of last year. The causes of 67, or 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·4 and 27·8 per 1000 in the preceding two weeks, declined again to 23·3 in the week ending May 15th. During the first six weeks of the current quarter the death-rate in the city averaged 26·8 per 1000; the mean rate during the same period did not exceed 18·8 in London and 19·0 in Edinburgh. The 158 deaths in Dublin last week showed a decline of 30 from the high number in the previous week, and included 8 which were referred to the principal zymotic diseases, against 13 and 14 in the previous two weeks; 3 resulted from "fever" (typhus, enteric, or simple), 2 from scarlet fever, 2 from whooping-cough, 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 8 deaths were equal to an annual rate of 1·2 per 1000, the rates from the same diseases being 2·2 in London and 3·1 in Edinburgh. The fatal cases of whooping-cough, which had been 5 and 7 in the previous two weeks, declined last week to 2. The 3 deaths from "fever," however, showed an increase upon the low numbers in the previous two weeks. Four inquest cases and 1 death from violence were registered; and 45, or more than a quarter, of the deaths were recorded in public institutions. The deaths of infants corresponded with the number in the previous week, while those of elderly persons showed a considerable decline. The causes of 22, or nearly 14 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

"THE PRESENT SYSTEM OF MEDICAL EDUCATION IN LONDON."

To the Editor of THE LANCET.

SIR,—Dr. Moxon attempts to solve the vexed question of the propriety of granting degrees in medicine to pass men of the Royal Colleges of Physicians and Surgeons, by suggesting that they should receive a degree bearing the stamp of an Albert University. If we read Dr. Moxon's interesting paper, we shall find that he speaks of the degree of the London University as being wholly unattainable by ordinary pass men, and as the edge of the unattainable to ordinary class men. He therefore proposes to brand these—I am afraid we must say third-class—men with the Albert degree, a degree which henceforth must bear the impress of inferiority. Whether a man's success in life as a practitioner depends upon his holding a degree in medicine or not, I cannot say. I only do know that hundreds of our best practitioners never have had a degree. I therefore question the propriety of issuing wholesale a batch of degrees, the very possession of which will at once mark the recipient as being below the average class man of our schools. Dr. Moxon enforces his argument by stating that the medical schools have so far improved in their teaching that they should now take rank as universities, and, as such, should therefore be able to guarantee to their respective students—as a reward for diligence—a degree in medicine. But I would ask, Have our universities been standing still while the medical schools have been making these grand strides? Have they not, too, improved as regards their teaching beyond all precedent?—improved also in certain definite lines—namely, that the best form of instruction is professorial, in other words should be centralised? With our medical schools it is the reverse, they are doing everything in their power to promote decentralisation. They are, in fact, vying, the one with the other, in providing scientific teaching, whereas their legitimate function is to utilise to the best of their ability the splendid mass of material they stand possessed of to promote clinical teaching in its widest sense. I believe I am right in asserting that true advanced university teaching of the day is becoming more and more opposed to "steps;" men are left more and more to themselves. The best teachers—professors—are obtained as instructors, but the men are less and less harassed by other lectures than those they prefer to attend. Is this the case with our medical schools in London? Are not our students surfeited with lectures, prescribed by the curriculum of the Royal Colleges, which, moreover, as they cannot themselves but doubtfully guarantee the quality, are careful to insist on quantity in its place?

Let the medical schools of London hand over their scientific teaching to universities and science schools. Let them confine themselves to purely professional matters, electing the various members of their staff rather with the view to professional knowledge than as teachers suitable to their science classes. Let the affiliated Colleges revise their curriculum, removing at least some of their "steps," and we shall soon find the Albert degree will be the one unasked for.

I am, Sir, yours faithfully,

DONALD W. CHARLES HOOD, M.D. Cantab.

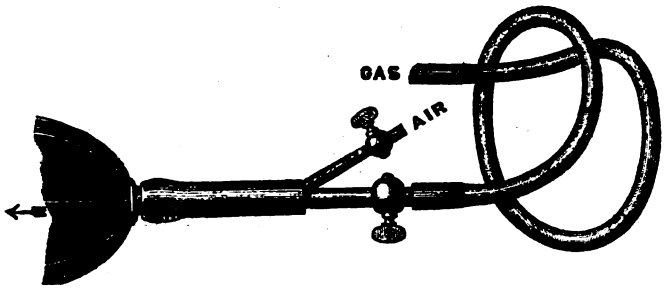
Green-street, Park-lane, May, 1886.

THE IMPORTANCE OF WORK IN THE WARDS.

To the Editor of THE LANCET.

SIR,—In THE LANCET of May 1st there was a letter quoting the opinion of Sir Benjamin Brodie on the effect of the "prize-giving" system on the education of medical students. In the succeeding number Mr. Buckston Browne sends an extract from Sir B. Brodie's autobiography, giving his opinion on the effects of the over-attendance on lectures. In the issue of May 15th a correspondent writes—Thirty years ago the system of medical instruction was as crude as the system of examinations was undeveloped." In the autobiography above mentioned Sir B. Brodie tells how he was appointed assistant-surgeon to St. George's Hospital in 1808, not being then twenty-five. Soon after his appointment Mr. Home left him the almost entire charge of his in-patients, and he shared with Mr. Robert Keate, the senior assistant-surgeon, the charge also of the patients of Mr. Gunning, who was doing duty with the army in the Peninsula. He says: "I had the opportunity at an unusually early age of acquiring a large experience in hospital practice; and to this circumstance my early professional success may very much be attributed. Six months in the year I passed several hours daily in the wards of the hospital, taking notes of the cases and communicating freely with the students. During the other six months the whole of the time I could spare from my employment as a teacher of anatomy was devoted to the hospital. The custom at St. George's, and indeed at all the other metropolitan hospitals, had hitherto been for the surgeons to go round the wards only on two days in the week, not attending otherwise except there were operations to perform or severe accidents which made their assistance necessary. Mr. Keate and myself were the first persons who adopted another mode of proceeding. We were at our posts in the hospital daily and superintended everything, and there never was an urgent case which we did not visit in the evening, and not infrequently at an early hour in the morning. This was of as much importance to the students as it was to the patients and ourselves, and the effect of it was soon perceptible in the increase of zeal and diligence on their parts and in their increasing numbers. After some time I appointed clinical clerks. I also began to deliver clinical lectures, and I believe that they were the first lectures of the kind which were ever delivered in a London hospital."

I am, Sir, yours truly,



May, 1886. F.R.C.S.

AN IMPROVEMENT IN PAQUELIN'S CAUTERY.

To the Editor of THE LANCET.

SIR,—Everyone who has used this instrument must know the extreme value it possesses when it will work properly; but I think there can be few who have not experienced an aggravation not equalled by anything that I know, by the instrument refusing to work exactly at the time when it is most wanted. I have tried many expedients to remove the difficulty, and have made many experiments to discover the causes of the failures. I have found that they lie chiefly in two directions—the most common being that by some accident the bottle of benzine has been tilted, so that a little of the fluid has run into the inside of the instrument. This renders it for a time perfectly useless, and sometimes permanently so. The second, and most frequent cause of failure is that the passage of the air over the surface of certain kinds of benzine does not enable it to become charged with a sufficient percentage of the inflammatory gas. I have therefore devised two methods of overcoming the difficulties. The first is to use ordinary domestic gas for the purpose of the cautery by the addition of a tube and double nozzle pipe, which is made perfectly clear by the accompanying woodcut. The pipe for the gas is slipped over

the burner of the gas jet, air is admitted by the second pipe, and the mixture takes place in the ball hand-pump, part of which is seen in the woodcut. The second method is, instead of having a bottle such as is usually provided with the cautery, to have one which is identical with the reservoir of Junker's apparatus for methylene, only of a considerably larger size. In this way the air is saturated with the benzine, and there is less risk from the shape of the bottle that the fluid benzine will run along the tube of the cautery. The improvements are neither complex nor expensive, and I find that they obviate many disappointments. I may say that for *heavy* work, such as the searing of pedicles of either uterine or ovarian tumours, or the searing of large surfaces of adhesion, I have devised a special form of gas cautery, which is for these purposes superior to Paquelin's. It is quite simple and never gets out of order, and can be had from Mappin and Co., 121, New-street, Birmingham.

I am, Sir, yours &c.,

Birmingham, May 17th, 1886. LAWSON TAIT.

"ROTHELN: A POINT IN DIAGNOSIS."

To the Editor of THE LANCET.

SIR,—The importance of the enlarged cervical glands, and the early stiffness of the neck resulting therefrom, as a "point in the diagnosis" of rotheln or rubeola being now raised in your columns, I may be pardoned for quoting two short sentences from an article "Rubeola, &c.," which you did me the honour of inserting in THE LANCET (vol. i., 1883, p. 995).

Describing the early symptoms of the disease, I then wrote: "Except the enlarged glands, *usually first to appear and last to go*, cough persists longest." And again, dealing with the glands: "Tender to the touch, *they give rise to the early stiffness of the neck*, and sometimes occasion actual pain." It is most satisfactory to me to find three members of the profession independently confirming these observations. My attention was first strongly directed to this "point" about 1879-80, when a patient was sent into hospital suffering from a feeling of malaise, stiffness of the neck and enlarged cervical glands, a temperature of 100° F., and naught else. As I had at the time several patients from the same house of business suffering from rubeola, I put the man aside as a possible case of that disease. Next day the supposition of the night before became established as a fact. I have since, especially in private practice, on a few occasions been able to confirm this observation. However, without the knowledge that a person so suffering had very recently resided in a house or district in which rubeola was rife, I should be disinclined to attach to this symptom any greater value than that of raising a *suspicion* of the disease. Another point to which I attached, and still do, importance—viz., symmetry in the glandular enlargement—has, I see, also been observed.

I am, Sir, yours faithfully,

Ladbroke-grove, W., May, 1886. W. TONGE-SMITH.

MANCHESTER.

(From our own Correspondent.)

THE VICTORIA UNIVERSITY.

AT the recent meeting of the Court of the Victoria University several important matters were considered. Dr. Greenwood resigned the Vice-Chancellorship, which office he has held since the establishment of the university, and regret is felt in many quarters that a change has had to be made. Professor Ward was unanimously elected to succeed him for a term of two years; no one took a more active and important part in the founding of the university, and the selection has given universal satisfaction. Dr. Greenwood and Professor Rendall, of University College, Liverpool, were elected pro-Vice-Chancellors. At the same meeting it was resolved to apply to Government for an annual grant from the national exchequer in aid of the expenses of the University, as it is without funds, except such as it derives from the two colleges at present affiliated to it. Another subject discussed was the extension of the work of the University in connexion with teaching bodies and educational institutions where instruction of various kinds is given. It was also resolved to make application to the Government for a separate representative on the Medical Council, in lieu of the proposed joint representation with Durham University, as provided in the Medical Act Amendment Bill now before Parliament. Our new Professor of Physiology has now got thoroughly to work in his new quarters, and at the inaugural address delivered by him on the 11th inst., he produced a very favourable impression upon his hearers: he concluded an interesting "introductory" by expressing a hope that the Victoria University might to some extent follow upon the lines of the Scottish universities, and make its degrees accessible to every student who worked in a fair and steady manner, and that they should not be beyond the reach of the average man to obtain.

THE ASSIZES.

The assizes now being held have had an unusual number of cases of homicide for trial, amongst them being that of a case of poisoning by a surgeon's assistant, already alluded to in these columns. Two patients, one a baby and the other a woman, both died with all the symptoms of opium poisoning after taking medicine supplied by the accused. In the first case, the magistrate acquitted the prisoner, but in the second, the case was sent to the assizes. Analysis showed morphia to be present to a very large extent, though no satisfactory explanation of how it came to be in the mixture was forthcoming at the trial. The jury returned a verdict of manslaughter, and a sentence of six months imprisonment was passed.

HEALTH AND RECREATION.

The open spaces committee of the Manchester and Salford Sanitary Association lately offered the corporation to take charge of the open space in Mount-street, Ardwick, and fit it with gymnastic appliances; and if the experiment of thus converting it into a recreation-ground should prove successful, to transfer all the appliances, &c., free of charge to the management of the Parks Committee. Steps have been taken to continue during the present summer the much-appreciated children's holiday movement, whereby children from our courts and alleys are sent out into the country for a period of three weeks. It is to be hoped that 1000

Digitized by Google

children may thus be sent within the next few months. It is stated that the cost per child is twenty shillings; all the work in connexion with the management of this beneficial scheme is voluntary and unpaid.

MEDICAL OFFICERS OF HEALTH.

The Sanitary Association has followed up its petition on the status and qualifications of medical officers of health by a deputation to the President of the Local Government Board on Friday, the 14th inst. Sir H. Roscoe introduced the deputation to Mr. Stansfeld, and Dr. Ransome explained to the President what it was the Association desired to bring before his notice, and the suggestions were favourably received by him.

The Local Board of Withington have decided to grant a fee of 2*s.* 6*d.* to every medical man supplying information of the existence of a case of infectious disease.

Manchester, May 17th.

LIVERPOOL.

(*From our own Correspondent.*)

THE ROYAL VISIT.

THE visit of Her Majesty to this city, extending from 8 A.M. on the 11th till 10 A.M. on the 13th, was a most successful one in all aspects except the weather. Instead of the proverbial Queen's weather, which might reasonably be anticipated in this "merry month of May," there were piercing winds and drenching rain combined—the weather was, indeed, as wretched as it could have been. In spite of this, however, the Queen, with a courage which was duly appreciated, went through the whole of the heavy duties which she had undertaken. On the first day of the visit, after travelling all night, she opened the International Exhibition with full State ceremonial. On the next day she was out in an open carriage for fully three hours, in addition to going for a trip on the Mersey. This, seeing that her sixty-seventh birthday rapidly approaches, is very satisfactory proof of her capacity of physical endurance, as well as her desire to comply with the wishes of her subjects, and to appear openly among them. In consequence of the precautions taken by the authorities to prevent accidents, noticed in a previous letter, not one occurred during Her Majesty's visit, though unfortunately one has occurred since. On Saturday last a triumphal arch, erected in a leading thoroughfare, fell down suddenly during a heavy north-west gale, causing severe injuries to several persons. The worst case is that of a lad aged eleven years, who sustained a concussion of the brain, but who is progressing fairly well. At the request of the Queen, conveyed through General Sir H. F. Ponsonby, the Mayor, Sir David Radcliffe, telegraphed the condition of the injured.

SIR DYCE DUCKWORTH.

The honour conferred upon this gentleman is an event of local interest, Sir Dyce being a Liverpool man. He is the youngest son of the late Robinson Duckworth, and was born in Liverpool in 1840. He was educated at the Royal Institution here, under the late Dr. Dawson Turner, after which he commenced a mercantile career in the office of Messrs. Holderness and Chilton, probably there acquiring business habits, which have been very useful to him ever since. He received his medical education at the Edinburgh University and St. Bartholomew's Hospital, graduating M.D.Edin. in 1863. Sir Dyce obtained high honours, the gold medal, and the prize for his thesis, "Observations on the Anatomy of the Suprarenal Capsules." He is a brother of Canon Duckworth.

REMOVAL OF A CITY CHURCHYARD.

For the purposes of city improvements the churchyard of St. Thomas, Park-lane, is in course of removal, the remains of those interred being removed for interment elsewhere, either by their surviving friends or by the authorities. In the latter case, the remains are conveyed to the new cemetery at Kirkdale, situated a few miles off. The church was built 136 years ago, on land outside Liverpool, in a lane leading to Toxteth Park. Now it is the centre of a thickly populated district, and hemmed in on all sides by houses and shops. The graveyard was never a public one, being laid out in vaults and graves, mostly bricked ones, for the use of private families of the better class. The soil was unsuitable, being a very stiff clay, and the tendency of vaults and bricked graves is to retain water. The contrast between this old burial-ground and our local cemeteries, where the soil is suitable, well-drained, and in accordance with the most recent sanitary requirements, is very striking. The churchyard was closed by Order in Council in 1854, but a few burials have been permitted in family tombs by the Home Secretary.

A SUICIDAL EPIDEMIC.

On the 15th inst. there were no fewer than five cases of attempted suicide brought before one of the borough justices. One was that of a married woman thirty-seven years of age, who had taken poison, and whose excuse was that she and her husband had been drinking together. The remaining cases were those in which suicide had been attempted either by the knife or poison, and in all drink had been the exciting cause of the rash act. This is confirmatory of an old tradition that May is a month for suicides.

Liverpool, May 18th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

SALT AND CHEMICALS.

A FEW years ago I gave you some particulars of the discovery by accident of a bed of salt of about 120 ft. in thickness in the valley of the Tees. Messrs. Bolckows and Vaughan, the great iron manufacturers near Middlesborough, were boring for water, when, to their great surprise, they came upon the bed of salt. This discovery has had the effect of giving considerable impetus to the chemical manufactures of the north, the decomposition of the chloride of sodium by sulphuric acid being, as it were, the first step in the manufacture of various chemicals of commercial importance. The chemical trade in the north has been for a considerable period in a languishing condition. A company who own the largest chemical works in the country were rather unfortunate last year in their explorations on the Tees for salt, but it is said that they also have now succeeded in reaching the salt bed, and are raising a considerable quantity, which is sent to their works here. The yearly consumption of salt at these great works is 27,000 tons, and the company expect to raise this quantity for their own supply. This acquisition must prove of immense importance in the economics of the chemical trade in its present state.

INTERNAL BURNS.

An inquest was lately held at Cleator Moor on the body of a labourer employed at one of the large ironworks situated near that place. The deceased, it appears, was breaking some red-hot metal, when he fell forward. He did not appear to be sufficiently injured to account for his death, but it was shown by Dr. Matthers that the deceased died from internal burns through inhaling hot air and sand from the iron bed.

DEATH UNDER CHLOROFORM AT NEWCASTLE INFIRMARY.

A death under chloroform took place last week at the Newcastle Infirmary. It was shown at the inquest by Dr. Maynard, house-surgeon, that the deceased, a quarryman, sustained an injury to his knee by falling on the pavement. Mortification set in, and symptoms of absorption of putrid matter. It was decided to amputate the thigh. Chloroform was given with due care, but just before the operation the patient died. It was further shown that on admission he was under the influence of drink, and the post-mortem disclosed old-standing disease of the heart, also fatty degeneration of the liver and kidneys; altogether he was a bad subject for the administration of chloroform, and for any operation without its aid.

TYPHOID ON BOARD THE "WELLESLEY."

One of the boys on board the *Wellesley* training ship in Shields harbour having been attacked by typhoid fever, he was, under the direction of the medical officer of the vessel, in order to prevent the possibility of the disease spreading, removed this week to the Tyne port sanitary authority's floating hospital at Jarrow. I believe there are at present between 300 and 400 boys on board the *Wellesley*. This

Digitized by Google

vessel is always considered one of the sights of the Tyne and the little sailors have so far been kept up to a high standard of health and general good behaviour.

UNIVERSITY OF DURHAM MEDICAL SOCIETY.

This young and sprightly Society gave a general entertainment last Friday in the Assembly Rooms in this city, which was highly successful in point of attendance and otherwise. Drs. Drummond, Mears, and others did the graceful honours of receiving the guests. Very few buildings in the north are so well adapted for an entertainment of this nature as the Assembly Rooms, and on this occasion they looked at their best. The attendance of practitioners and their friends from a distance was very numerous, special trains being provided for the visitors from Sunderland, South Shields, &c. Every thought was considerately shown for the comfort of the guests, and the University of Durham Medical Society deserves to be congratulated upon the success of this brilliant affair.

Newcastle-on-Tyne, May 16th.

EDINBURGH.

(From our own Correspondent.)

EDINBURGH UNIVERSITY COURT.

AT its meeting on the 17th inst. the Court formally sanctioned the arrangements by which a schoolmaster's diploma is to be conferred by the University of Edinburgh. A final assent was also given to the regulations for the new lectureship on the Philosophy of Natural History, to which Mr. Romanes has been appointed for a term of five years. This course is to consist of six lectures annually, to be delivered in the University, and to be free to all matriculated students; the necessary funds to endow the lectureship having been provided by the Earl of Rosebery, acting upon the advice of Professor Cossar Ewart.

THE ROYAL SOCIETY OF EDINBURGH.

An important paper by Dr. Griffiths has been communicated to the Society by Professor Crum-Brown, dealing with the effects of ferrous sulphate in destroying the spores of certain parasitic fungi which attack farm crops. Dr. Griffiths, amongst other species, has made a special study of the *Penospora infestans*, the cause of the potato disease. The spores of this organism may be kept as a dry dust for many months without losing their vitality. Following the lines of Duclaux's classical researches, Dr. Griffiths has tested the vital relation of these spores to a variety of chemical agents. Potash salts prove highly favourable to their development, whilst ferrous sulphate, although in general a very valuable plant food, is found to exert a selective devitalising influence upon the *Penospora*. A weak solution of the salt applied to a diseased plant was found to destroy the parasite, whilst it left the structure of the higher organism uninjured. Dr. Griffiths recommends as a practical outcome of these researches that in warm, damp seasons, when the disease is specially liable to be developed, manures should be employed, in the composition of which potash salts should have their place taken by small quantities of ferrous sulphate. A paper by Mr. Kidston was read at the same meeting, showing that what have been considered as fossil parasitic fungi in certain ferns from the carboniferous formations are in reality a form of fructification. Lord Rayleigh, M. Milne-Edwards, the Abbé Renard, and Professors Newton and Thalen have been elected honorary Fellows of the Society.

A SUBURBAN HOSPITAL FOR INFECTIOUS DISEASES.

In consequence of the change of arrangements which has placed the City Fever Hospital under the direct control of the Corporation of Edinburgh, it has become necessary to meet the requirements of the outlying districts, which can be no longer provided for at the expense of the City ratepayers. The Board of Supervision for Scotland has accordingly issued notices to the various rural authorities calling upon them to provide hospital accommodation for such cases of infectious disease as occur within their jurisdiction. A plan has been submitted by which these authorities can join in supporting a single institution which will supply the needs of all, upon a system of proportional maintenance based on the census reports from each district. It is expected that this will be generally acquiesced in, and already plans for the proposed hospital are in course of preparation.

ROYAL PHYSICAL SOCIETY.

The annual dinner of this Society was held on the 14th inst., the chair being occupied by Professor Sir W. Turner, F.R.S., the President of the Society. In proposing the toast of the Royal Physical Society, the chairman gave an interesting *résumé* of its history, which has extended over more than a century, and referred to the existence of such bodies as an index of, as well as a stimulus to, the intellectual and scientific life of a community. In replying to the toast of the Universities of Scotland, Professor Chiene reviewed the present flourishing condition of the Universities of Edinburgh, Glasgow, and Aberdeen, and said it was the duty of all loyal Scotsmen to do everything in their power to support the smallest and the oldest of the Scottish Universities, St. Andrews. He advocated the affiliation of the rapidly prospering University College of Dundee to the old University, as a measure calculated to prove of the very highest value to both institutions.

Mr. F. Grant Ogilvie, M.A., B.Sc., F.R.G.S., of Gordon's College, Aberdeen, has been appointed Principal of the Heriot-Watt College, a most important institution in Edinburgh for providing secondary education in technical subjects and in natural science for the classes whose primary education is provided for by the School Board.

Dr. D. Noël Paton, of Edinburgh, has been appointed Examiner in the Institutes of Medicine and in Zoology in the University of Aberdeen.

Edinburgh, May 18th.

PARIS.

(From our own Correspondent.)

PRESENTATION TO M. CHEVREUL.

AFTER an illness of two or three months, M. Chevreul, the illustrious centenarian, paid his first visit yesterday to the Academy of Sciences. On his entry the whole assembly rose to welcome his return amongst them, and the president, Jurien de la Gravière, took the opportunity of tendering him the congratulations of the Academy on his recovery. It had been decided that some token should be presented to M. Chevreul to commemorate his 100th birthday, which, although it does not take place until Aug. 31st next his colleagues, most of whom would be away for their holiday, were anxious to anticipate by offering him their congratulations, accompanied by a magnificent statue in bronze representing History, which was designed by M. Paul Dubois, the well-known sculptor. The president then, in very neat and touching terms, traced the life and works of this hero of the day, in doing which he said that the members of the Academy congratulated their venerable colleague, not only for the green old age that he had attained, but for the good use he had made of his life. M. Chevreul then rose, and, although under the influence of great emotion, thanked the Assembly, in a distinct and audible voice, for this mark of their affection and esteem, and added that it was mainly to temperate living that he attributed his longevity.

DISTURBANCE AT THE SCHOOL OF PHARMACY.

A disturbance took place at the Paris School of Pharmacy — a rather unusual circumstance — on the occasion of the opening lecture of the summer session by M. Chatin, Professor of Botany. When the professor began to speak he was interrupted by groans and shouting, whilst raw eggs, potatoes, and pebbles were hurled, but fortunately fell short of the rostrum. The students, on an inquiry being made, could formulate no grievance against their professor, but it oozed out that he was too much of a botanist for them, as he preferred the study of plants to that of chemistry. The fact is, M. Chatin is rather severe at the examinations, and it is only those students who are backward in botany who complain of the inordinate zeal of the professor in that particular branch, especially as he required them to accompany him every Sunday to the country for the purpose of

Digitized by Google

herborisation, which was distasteful to the students, as it spoiled their Sunday holiday. Notwithstanding the interruptions, M. Chatin continued his lecture to the given time (one hour), and on his retiring a most disgraceful scene took place, projectiles being thrown in all directions. In the mêlée Dr. Flahaut, Professor of the Faculty of Montpellier, a former pupil of M. Chatin, and who came to attend the lecture, attempted to remonstrate with the students, when he was struck on the head with his own umbrella, causing a wound, which, however, is not of a serious nature. In his report to the Minister of Public Instruction of the disturbance M. Chatin sent in his resignation as director of the school, but not as professor of botany, as he considered the study of that branch, as well as chemistry, indispensable to pharmacology. As there seemed to be no signs of reconciliation on the part of the students, the Minister of Public Instruction has thought proper to close the school for the present.

DEATH OF DR. HENRI FAUVEL.

Dr. Henri Fauvel, a distinguished chemist, son of the late physician of the Hôtel Dieu, and the well-known hygienist, was accidentally drowned a few days ago while making some experiments with the Seine water near the bridge of Epinay, just outside Paris. He was a young man of great promise, and was a former pupil of the late Professor Wurtz. He was attached to the Municipal Laboratory of Paris, where he greatly distinguished himself as an analyst and hygienist.

Paris, May 15th.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the Fellows of the Royal College of Physicians was held on the 20th inst., Sir W. Jenner, Bart., President, in the chair. The intimation by the President that Her Majesty had been pleased to confer the honour of knighthood upon Dr. Dyce Duckworth, treasurer of the College, in recognition of his services in connexion with the Examination Hall, was received with applause.

A Report from the Medical Bill Committee was read. It advised the introduction into Clause 3 (*a*), enumerating the bodies competent to hold qualifying examinations, of the words "or medical corporation" after the word "university"; in Clause 4 the omission of the words "assigning power to the Privy Council, to reinstate medical authorities which have been previously deprived of their rights to hold qualifying examinations"; and the total omission of Clause 5, which provides for qualifying examinations by single corporations, with the assistance of examiners appointed by the Medical Council. The Committee also expressed their high opinion of the existing examinations for certificates in Sanitary Science, and deemed the suggestion that such certificates should be capable of registration worthy of being entertained. It was pointed out by Sir H. Pitman that both Sir Lyon Playfair and Sir H. Holland had given notice of amendments in the Bill to introduce the official recognition of such certificates. The report was adopted, an amendment declining to press the subject of registration of Sanitary Science qualifications being rejected.

A Report from the Building Committee was read. After alluding to the ceremonial of March 24th, it stated that the Examination Hall will probably be completed and ready for occupation next year, on the anniversary of the day on which foundation stone was laid. The Committee also drew attention to the unoccupied plot of ground adjoining the Hall, which was also in the possession of the two Colleges. In adopting the Report the College referred the question as to how that site may best be utilised to a special committee, to confer with a committee of the College of Surgeons upon the subject.

The Report of the Croonian Trust Committee was again brought under notice, and several alternative schemes and proposals were discussed. No decision was arrived at, the consideration of the matter being again adjourned.

MEDICAL NOTES IN PARLIAMENT.

The Medical Acts Amendment Bill.

IN the House of Commons on the 17th inst., in reply to Dr. Farquharson, Sir L. Playfair said he did not propose to do more that night than to get the Bill into committee and immediately report progress.—Mr. F. Powell suggested that as the right hon. gentleman had several important amendments to propose, it might be well to commit the Bill *pro formâ*, in order that it might be reprinted with the amendments. Sir L. Playfair said he did not think the character of the amendments rendered that course necessary; they referred mostly to matters of detail. The House afterwards went into committee on the Bill, and, in accordance with the above statement of Sir Lyon Playfair, progress was immediately reported.

Small-pox at Wooburn

On the 18th inst., Mr. Borlase, in reply to Mr. Lawson, said he very much regretted the outbreak of small-pox at Wooburn Mills. The Local Government Board had no authority under which they could secure the disinfection of rags used in paper-making so as to prevent contagion. The Board had enforced the vaccination and revaccination of those engaged in paper-making as the most valuable means of protecting them from small-pox.

THE SERVICES.

INDIA OFFICE.—The Queen has approved of the following amongst other promotions among the officers of the Staff Corps and Indian Military Forces made by the Governments in India:—Surgeon Percy Hugh Benson, Surgeon John Lancaster, and Surgeon Walter Gawen King, all of the Madras Medical Establishment, to be Surgeons-Major.

ADMIRALTY.—The following appointment has been made:—Surgeon Eli T. Eds, to the *Triton*.

Obituary.

DR. ROBERT SCOTT ORR.

WE regret to announce the death of Dr. Robert Scott Orr of Glasgow, which took place very suddenly on May 15th. Dr. Orr was a native of Edinburgh, his father being a member of a well-known firm of chemists. He was apprenticed to Sir George Newbegging, a surgeon in that city, and studied at the University, graduating in medicine there in 1840. Subsequently he went to Glasgow as assistant to Dr. Hutcheson of the Royal Asylum for Lunatics, Gartnavel, and, after some valuable experience there, he was appointed in 1843 Superintendent of the Glasgow Royal Infirmary. He signalised his period of office by publishing annually a very valuable series of statistical tables of the cases in the hospital. On leaving the infirmary he practised for several years in Dunoon, one of the Clyde watering-places, and formed a connexion with visitors from Glasgow, which stood him in good stead in after-life. For more than thirty years he has been a well-known Glasgow physician and consultant, and has occupied a prominent place in the Faculty of Physicians and Surgeons. He was president of that corporation from 1880 to 1883; and for the last eight years he has been the member of the General Medical Council elected by the Faculty, and has gained the esteem of his fellow-councillors by his sound judgment, courtesy of manner, and unswerving rectitude and devotion to his trust. For several years he acted as Extra-professorial Examiner in the University of Glasgow, and also an examiner in medicine to the Faculty of Physicians and Surgeons. He was long a physician to the Royal Infirmary, and as such he was an accurate and painstaking observer of disease, and was loved as few men are loved by the patients under his care. The *Glasgow Medical Journal* was frequently enriched by the records of the results of his hospital experience.

Glasgow can ill spare a man like Dr. Scott Orr, for he was the friend of aspiring talent, and helped by kind word and

Digitized by Google

generous deed many a young practitioner during their early struggles. In all the years of his professional life we firmly believe he made no enemies. His remains were followed to the grave by a large number of his professional brethren. Dr. Orr was sixty-seven years of age, and leaves three sons and four daughters. One of his sons is a medical practitioner in Kensington.

MALACHY J. KILGARRIFF, F.R.C.S.I.

THIS gentleman died at his residence, in Harcourt-street, Dublin, on the 18th inst., after a tedious illness, aged forty-six years. The deceased was formerly a demonstrator and lecturer on anatomy in the Ledwich School of Medicine, and afterwards became one of the visiting surgeons to Jervis-street Hospital; he was finally elected a member of the surgical staff of the Mater Misericordiæ Hospital, which appointment he held at the time of his death. He had been in very bad health for a considerable time past, and those who knew him intimately were aware of the inevitably fatal nature of his malady. His contributions to surgery included a case of Genu Valgum, operated on by Ogston's method successfully. Mr. Kilgarriff leaves a widow and family to mourn his untimely decease.

PROF. HANS GIERKE.

THE University of Breslau has lost one of the most popular of its medical staff in Dr. Gierke, who died on the 8th inst. in the Maison de Santé at Schöneberg, near Berlin. Hans Paul Bernhard Gierke, brother of the well-known Professor of Law in the University of Heidelberg, was born on the 19th of August, 1847, at Stettin. After completing his academic studies he came before the public with his first scientific work, "Ueber das Athmungscentrum" ("On the Respiratory Centre"). At the instance of Dr. Kölliker, he went in 1876 to Tokio to fill the Chair of Anatomy in the Imperial University of the Japanese capital. By that time, however, the seeds of a lingering malady had declared themselves, and in 1881 he returned home to assist Professor Heidenhain in the Physiological Institute at Breslau, where he was appointed in the following year Extraordinary Professor. Advancing illness compelled him to seek a more southern climate, but the change brought him no benefit. Before his death his valuable collection of Japanese objects was exhibited in the Industrial Art Museum of Berlin, while his rich assortment of Japanese pictures was purchased by the State for the Ethnographic Museum of the same city.

BRIGADE SURGEON TYLER OUGHTON.

MR. TYLER OUGHTON, whose death occurred from heart disease on the 13th inst., was born in Jamaica in 1836, and received his professional education at St. Thomas's Hospital. Having become a Member of the Royal College of Surgeons of England in 1858 and a Licentiate of the Society of Apothecaries in 1859, he entered the army in 1861, and served for several years in Western Africa and in India. He was engaged in the last Ashantee and Afghanistan wars, and marched with General Roberts from Cabul to Candahar, taking part in the subsequent victory. In 1881 he retired from the service and devoted his remaining years to scientific study, the result of which is contained in a series of articles on Vision contributed to the columns of this journal.

ACCIDENT TO MR. WILLIAM ADAMS.—We regret to learn that Mr. William Adams met with a rather serious accident at the Colonial and Indian Exhibition on Thursday last. In walking through one of the courts he stumbled over a chair, and fell against a glass case, wounding his hand and wrist somewhat severely.

PRESENTATION.—The patients and other friends of Dr. Douglas Reid, of Helensburgh, recently presented that gentleman with a very handsome horse and brougham, as an indication of the high esteem in which he is held throughout the district in which he practises.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following gentlemen have passed the examination for the degree of B.S.:—

G. Bulstrode, Emmanuel; R. Coombe, Caius; B. Evans, King's; G. C. Fitzgerald, Caius; A. S. Percival, Trinity; T. Rushbrooke, Christ's; S. S. Sprigge, Caius; H. M. Sympson, Caius; H. J. Tatham, Clare; G. Winfield-Roll, Christ's.

At a congregation held on the 13th inst., the Vice-Chancellor, Sir George Paget, Professor Humphry, Professor Latham, Professor Macalister, Dr. Donald Macalister, Professor Liveing, Professor Foster, and Mr. Trotter, Trinity, were appointed a syndicate to take into consideration the Medical Acts Amendment Bill, and to take such steps with reference thereto as they may think fit. Dr. F. B. de Chaumont (Edinburgh), Dr. Alfred Carpenter (London), Dr. Hubert Airy (Trinity), and Sir Charles A. Cameron, President of the Royal College of Surgeons in Ireland, were appointed examiners in State Medicine.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 13th inst.:—

Alexandrian, Nazareth, Scutari, Constantinople.
Atkinson, John Lancelot, St. George's-square.
Barnes, Robert Newton, Ash House, Bishop's Waltham, Hants.
Bell, John Charles, Merlin, Ontario, Canada.
Englebach, Frederick George, Richmond, Surrey.
Jones, Josiah Herbert, Hoe-street, Walthamstow.

THE thirty-fourth annual meeting of the governors of the Hospital for Sick Children was held on the 19th inst.

AT a public dinner held on the 19th inst., on behalf of the funds of the Public Dispensary, Stanhope-street, Clare-market, subscriptions to the amount of £320 were announced.

ON the 19th inst., the fortieth annual meeting of the supporters of the House of Charity, the oldest convalescent home, was held, when a satisfactory report was presented and adopted. The income last year amounted to £1853.

A BAZAAR in aid of the People's Palace for East London (the Beaumont Trust) will be held in the Duke of Wellington's Riding School at Knightsbridge on Wednesday, June 2nd, and two following days.

A SUB-COMMITTEE of the Rivers Committee of the Manchester City Council has been appointed to take into consideration a scheme for dealing with the whole of the sewage of the city.

COTTAGE HOSPITAL FOR FAVERSHAM.—Mrs. W. T. Townend Hall, lately of Syndale Park, Faversham, has generously offered to provide funds for the building of a cottage hospital for the town, in memory of her late husband, who died some twelve months since.

ON the 19th inst., at the twentieth annual meeting of the Governors of the Victoria Hospital for Children, Queen's-road, Chelsea, it was reported that the number of in-patients admitted last year was 550, and total attendances of out-patients 30,898, and at the convalescent branch at Margate 146.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Library of the College will be closed on Thursday, the 27th inst., for the Clinical Examination; and on Friday, the 28th inst., at 4 o'clock, for the *viva-voce* part of the examination for the Final Fellowship, for which twenty-eight candidates have entered their names.

METROPOLITAN FREE HOSPITAL. — The fiftieth anniversary of this institution was commemorated by a banquet on the 12th inst., when the chairman, Mr. Cyril Flower, M.P., stated that the new building in Kingsland-road was constructed to contain 160 beds, one-fourth of which would specially be set apart for the accommodation of patients of the Jewish persuasion. The out-patient department is already in full operation. The amount required for carrying on the work of the hospital is from £8000 to £9000 per annum. During the evening subscriptions amounting to nearly £2200 were announced.

Digitized by Google

MORLEY HOSPITAL.—On the 17th inst., a bazaar was opened in aid of the funds of this seaside convalescent home for the working men of London, which was established in 1883, at St. Margaret's Bay, near Dover. The object of the bazaar is to remove a debt of £2000 incurred in the purchase and furnishing of premises suitable for the purpose of the home, and this incubus being removed, it is estimated that the institution will be self-supporting.

ST. JOHN AMBULANCE ASSOCIATION.—An ambulance class composed of officers and non-commissioned officers of the 45th Regimental District Headquarters was examined at Derby on the 6th inst. by Dr. J. W. Martin, who reports very favourably of the manner in which all the pupils passed the examination. The examiner lays great stress on the importance of this subject to all branches of this service, and strongly urges the formation of similar classes elsewhere.

THE HOSPITALS ASSOCIATION.—On the 19th inst. the sixth general meeting of the members of this association was held, when a paper on the Ambulance Arrangements of an English Army was read by Surgeon-Major Evatt. The formation of a Volunteer Medical Staff Corps to supplement the existing regimental surgeons and ambulance men and to provide bearer companies and field hospitals for the Volunteer forces was strongly advocated. A discussion followed.

NORTH-EASTERN HOSPITAL FOR CHILDREN, HACKNEY-ROAD, E.—At the eighteenth annual meeting of the supporters of this hospital on the 17th inst., it was reported that the institution was in a much better position than last year, the income showing a slight increase over the amount received in the preceding year. The number of in-patients relieved was 653, as against 620 in 1884, and the out-patients numbered nearly 1000 per week. Funds are still required to pay off a debt of £1600 to the bankers, and for this the committee earnestly appeal.

M. PASTEUR.—It is reported that M. Pasteur has been so favourably impressed by the scientific intelligence of an American physician, Dr. Valentine Mott, of New York, that he has, for the first time, broken through his rule not to allow his virus go out of his own hands. The Czar has just conferred on M. Pasteur the Order of St. Anne of the First Class, with diamond insignia; and other decorations on the physicians and surgeons who co-operated with the eminent *savant* in the treatment of the wolf and dog-bitten Russians.

PROVIDENT SURGICAL APPLIANCE SOCIETY.—The annual dinner in aid of the funds of this institution was held on the 19th inst., when it was stated by the Duke of Portland, who occupied the chair, that not less than 4300 instruments, some of them of a most expensive character, were given to poor people last year, and the total number of instruments which had been distributed since the formation of the Society was more than 40,000. A list of subscriptions amounting to £1072, as against £950 at the last dinner, was announced by the secretary.

COLONIAL AND INDIAN EXHIBITION.—The Reception Committee, recently formed by direction of H.R.H. the Prince of Wales, Executive President of the Royal Commission, is desirous of offering a fitting and cordial reception to Colonial and Indian visitors of distinction during their visit to England, by facilitating, so far as may be possible, their arrangements for visiting places of special interest in the United Kingdom. To enable the Committee to do this funds are required; and those who may be desirous of co-operating are invited to subscribe to the object in view. Subscriptions can be sent to the London and Westminster Bank, West-end Branch, St. James's-square, S.W., or to Mr. Arthur Hodgson, C.M.G., General Secretary, at the office of the Reception Committee, "Old London," Exhibition Buildings, South Kensington, or to Mr. H. Trueman Wood, the Treasurer, Society of Arts, John-street, Adelphi. Cheques should be crossed London and Westminster Bank, West-end Branch.

THE POLLUTION OF THE LEA.—At the meeting of the Select Committee appointed to report on the purification of the River Lea on the 14th inst., Mr. Grantham, engineer to the Enfield Board of Health, described the drainage works and sewage farm at Enfield. He stated that the farm consisted of ninety-five acres, and the tanks were capable of containing 480,000 gallons of sewage, which was carried to all parts of the farm by means of pumps. In dry weather the sewage matter pumped upon the farm was 480,000 gallons, but in wet weather the quantity increased to as much as 2,200,000 gallons. As far as Enfield was concerned, if the existing intervening cut was widened and deepened it would be satisfactory; but it would be a more desirable scheme, if the cost was not wholly disproportioned to the advantage, to have the sewage kept out of the river. Mr. Bailey Denton having given evidence as to a scheme which he prepared some years ago for the drainage of the valley of the Lea, the committee adjourned.

BANQUET AT THE ACADEMY OF MEDICINE, IRELAND.—Dr. Robert McDonnell, President of the Academy of Medicine, Dublin, had the honour of entertaining on Wednesday, the 12th inst., at dinner, at his residence, Merrion-square, his Excellency the Lord-Lieutenant and his Serene Highness Prince Edward of Saxe-Weimar, Commander of the Forces in Ireland. The following representatives of the different sections of the Academy of Medicine and other gentlemen were invited to meet his Excellency:—Dr. Cruise, Medical Section; Sir Charles Cameron, Surgical Section; Dr. More Madden, Obstetrical Section; Dr. Little, Pathological Section; Dr. Duffy, Treasurer; Dr. Thompson, Secretary; Col. Turner, Private Secretary to the Lord-Lieutenant; the Provost of Trinity College; Sir Robert Hamilton, Assistant Secretary; Sir Patrick Keenan, Commissioner of National Education; Mr. Robinson, Vice-President of the Local Government Board; Mr. McCausland; and the Aides-de-Camp of the Lord-Lieutenant and the Commander of the Forces. Twenty in all sat down to dinner.

BRITISH ASSOCIATION.—The programme of arrangements for the Birmingham meeting of this Association has just been issued. It will meet on Wednesday, Sept. 1st, when Sir Lyon Playfair resigns the presidency, which will be assumed by Sir William Dawson, C.M.G., F.R.S., the eminent Canadian geologist, Principal of M'Gill College, Montreal. The local secretaries are Mr. J. Barham Carslake, the Rev. D. H. W. Crosskey, and Mr. C. J. Hart; and the local treasurer is Mr. J. D. Goodman. The following are the presidents of the various sections:—*(a)* Mathematical and Physical Science, Professor G. H. Darwin, F.R.S.; *(b)* Chemical Science, William Crookes, F.R.S.; *(c)* Geology, Professor S. G. Bonney, F.R.S.; *(d)* Biology, William Carruthers, F.R.S.; *(e)* Geography, General Sir F. J. Goldsmid, K.C.S.I., C.B.; *(f)* Economic Science and Statistics, John Biddulph Martin, F.S.S.; *(g)* Mechanical Science, Sir James N. Douglass, M.I.C.E.; *(h)* Anthropology, Sir George Campbell, K.C.S.I., M.P. On Thursday evening, Sept. 2nd, there will be a *soirée*; on Friday, the 3rd, at 8.30 P.M., a discourse on the "Sense of Hearing," by Professor W. Rutherford, M.D., F.R.S.; on Monday evening, the 6th, at 8.30, a discourse on "Soap Bubbles," by A. W. Rücker, M.A., F.R.S.; and on Tuesday evening, the 7th, at 8 P.M., a *soirée*.

UNIVERSITY COLLEGE.—On the 19th inst., the prizes in connexion with the Faculty of Medicine were distributed by the Earl of Kimberley. In the class of Surgery the gold medal was won by Mr. H. H. Brown, and the silver medals were presented to Mr. E. R. St. C. Corbin and Mr. S. C. Holder. In the senior class of Physiology, gold medals were awarded to Mr. H. M. Fernando and Mr. J. L. Firth; in the junior class, a silver medal was awarded to Mr. C. A. Kent. In the senior class of Anatomy, the gold medal was gained by Mr. J. B. M. White, the first silver medal by Mr. H. M. Evans, and the second silver medal by Mr. W. H. Tate; in the junior class, the silver medal was awarded to Mr. L. E. Hill. In Medicine, the gold medal was awarded to Mr. J. E. Rennie, and silver medals to Mr. K. N. Bahadhurji and Mr. W. P. May. In Practical Chemistry, the gold medal was awarded to Mr. H. A. Eccles, the first silver medal to Mr. H. Tilley, and the second to Mr. A. Vaughan. In Pathological Anatomy, the Tuke medal was gained by Mr. S. E. Holder. In the senior class of Clinical Medicine the following Fellowes medals were awarded:—Gold to Mr. Sydney E. Holder, silver to Mr. J. J. Lister and Mr. F. S. Toogood; in the junior class, the silver Fellowes medal was awarded to Mr. C. W. Jecks. In Clinical Dental Surgery, the prize was gained by Mr. E. R. St. C. Corbin. A large number of certificates were also awarded.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BAILEY, J. RIDLEY, M.B.Edin., has been reappointed Medical Officer of Health for Bilston.

BLACKWOOD, ARTHUR, M.D., M.Ch., has been appointed Assistant Medical Officer to the Liverpool Parish Hospital, vice W. Piercy Fox, resigned.

CHEESMAN, G. E. A., L.R.C.P.Ed., L.S.A.Lond., has been appointed Medical Officer for the First District of the Lymington Union.

DAVIES, D. S., M.B.Lond., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer of Health to the City and Port Sanitary Authority of Bristol, vice Davies, resigned.

DAVIES, ELEAZER, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Pontlottyn District of the Merthyr Tydfil Union.

FRASER, ALEXANDER G., M.A.Aber., M.B., C.M.Edin., has been appointed Honorary Physician to the Hulme Dispensary, vice G. J. Haslam, M.D., M.R.C.S., resigned.

HINDS, FRANK, M.B., B.S.Lond., M.R.C.S., has been appointed Junior Resident Medical Officer to the Hospital for Sick Children, Great Ormond-street, W.C.

MAUNSELL, FRANCIS J., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Tir Phil District of the Merthyr Tydfil Union.

MOIR, JOHN, L.R.C.P.Ed., Medical Officer to the West Ham Union Infectious Diseases Hospital, has been reappointed Medical Officer to the West Ham Local Board Cottage Hospital, Plaistow, E.

MORSE, SYDNEY, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Cannock District of the Cannock Union.

PARRY-JONES, M., M.D., B.S.Lond., M.R.C.S., L.S.A.Lond., has been appointed Resident Surgeon to the Pinxton Collieries, Alfreton.

PARTINGTON, WILLIAM, M.B., C.M.Glas., has been appointed Medical Officer for the Workhouse and the Tunstall District of the Wolstanton and Burslem Union.

RAKE, HERBERT VAUGHAN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer of Health for the Fordingbridge Union.

THOMAS, J. L., M.D.Aber., has been appointed Physician to the Royal South Hants Infirmary, vice Dr. Broster, deceased.

Births, Marriages, and Deaths.

BIRTHS.

BLACKBURN.—On the 12th inst., at Margravine-gardens, West Kensington, the wife of H. B. Blackburn, M.R.C.S., of a daughter.

GRAHAM.—On the 6th ult., at Bindjey, Sumatra, the wife of J. Campbell Graham, M.D., of a daughter.

MORRISSON.—On the 17th inst., at Strathallan, St. Saviour's-road, Brixton-hill, the wife of Stammers Morrisson, L.R.C.P.Lond., M.R.C.S., of a daughter.

MARRIAGES.

BARTON—GASSIOT.—On the 15th inst., at St. Mary Abbott's Church, Kensington, A. B. Barton, M.D., of Lexham-gardens, Kensington, to Harriet, second daughter of the late J. P. Gassiot, J.P., F.R.S.

HICKS—POTTER.—On the 13th inst., at Madeira, at the British Consulate, and afterwards at the English Church, Frederick John Hicks, M.A., M.B.Oxon., to Sarah Emma (Dollie), eldest daughter of the late Philip Potter, of Larklands, Ilkeston.

OLIVER—BURFORD.—On the 13th inst., at the Wesleyan Church, Hampstead, Francis George Oliver, L.R.C.P.Lond., M.R.C.S., eldest son of Frank Oliver, Esq., of Negapatam, India, to Kate, youngest daughter of Mr. James Burford, of Norway House, Hampstead, N.W.

REED—HIGHAM.—On the 13th inst., at Charles Church, Plymouth, William Cash Reed, M.D., to Eleanor Winifred Maude, youngest daughter of the late James Higham.

RUTHERFORD—TWEDDELL.—On the 18th inst., at the Parish Church, Gosforth, Newcastle-on-Tyne, Robert Leonard Rutherford, M.D., of Jesmond, Newcastle-on-Tyne, to Mary Alice, third daughter of the late George Tweddell, of West Hartlepool.

SHEPERD—BEALE.—On the 13th inst., at Christ Church, Hoxton, by the Rev. Robert J. Sheperd, L.R.C.S.I., L.K.Q.C.P.I., of Pemberton House, Hay, Breconshire, to Mary Kathleen, daughter of the late George Beale, Esq., of Dublin.

DEATHS.

HANDS.—On the 17th inst., at Shepherd's-bush-road, Joseph Hands, M.R.C.S., late of The Grove, Hammersmith.

LIVESEY.—On Feb. 1st (of exhaustion, following rheumatic fever), Ernest Livesey, M.R.C.S., L.S.A.Lond.

MEDLEY.—On March 27th, on board s.s. *Glengarry*, off Hongkong, Harold Thomas Dupuis Medley, M.R.C.S., L.R.C.P., in his 26th year.

ORR.—On the 15th inst. (very suddenly), at Albany-place, Glasgow, Robert Scott Orr, M.D., aged 67.

OUGHTON.—On the 13th inst., at 20, Buckingham-road, Brighton (after a short illness), Brigade-Surgeon Tyler Oughton, aged 49 years.

STUDDERT.—On the 14th inst., at Liverpool, Reginald Waller Studdert, M.B., B.C.L., aged 24.

TREACHER.—On the 14th inst., at New, John Gawaron Treacher, M.R.C.S., late of Laban, aged 72.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, May 24.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

SOCIETY OF ARTS.—8 P.M. Dr. B. W. Richardson: Animal Mechanics (Cantor Lecture).

Tuesday, May 25.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.

SOCIETY OF ARTS.—8 P.M. Mr. G. Gordon Hake: Cyprus since the British Occupation.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Mr. Reginald Stuart Poole: The Ancient Egyptian Classification of the Races of Man.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Lockwood: The Morbid Anatomy and Pathology of Encysted and Infantile Hernia.—Dr. Fletcher Beach: A case of Imbecility with Choroid Movements.—Dr. Steavenson and Mr. Bruce Clarke: The Treatment of Stricture of the Urethra by Electrolysis.

Wednesday, May 26.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Mr. Lawson Tait and others.—Dr. Fancourt Barnes: On a case of Pyometra.—Dr. Grigg on Pyosalpinx in the Puerpera. Council Meeting at 8 P.M.

Thursday, May 27.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Professor Alexander Macalister: Habit as a Factor in Human Morphology.

Friday, May 28.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Report of Urinary Tests Committee. Dr. Caton (Liverpool): Aneurysm of Hepatic Artery.—Mr. R. W. Parker: On the Treatment of Nævus by Excision, to which is appended a Clinical Analysis of 564 cases of Nævus, together with the Microscopic Nature of this Condition.—Mr. Victor Horsley: A case of Suppuration of the Mastoid Cells complicated by Thrombosis of the Right Lateral Sinus and Septic Embolism of the Heart and Left Lung, in which Recovery followed Trephining of the Mastoid Process, with remarks on the Prevention of Septic Embolism in such cases.—Dr. Hale White: On Simultaneous Inflammation of several Serous Membranes.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. Oliver Lodge: Electrical Deposition of Dust and Smoke.

Saturday, May 29.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. G. G. Stokes: Light, with special reference to Effects resulting from its Action on Various Substances.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

ALCOHOL IN WORKHOUSES.

THE return required by the Local Government Board, showing the quantities of wines, spirits, and malt liquors consumed in the workhouses for the year 1885, was laid before the guardians of the St. Saviour's (Southwark) Union on the 13th inst. The particulars were as follows:—Christchurch workhouse—spirits, 456 pints; wines, 55 pints; malt liquors, 2218 gallons. The average number of inmates was 506. St. George's Workhouse—spirits, 58 pints; wines, *nil*; malt liquors, 2553 gallons. The average number of inmates was 424. Newington Infirmary—spirits, 506 pints; wines, 222 pints; malt liquors, 5356 gallons. The average number of inmates was 1020.

H. S. (Birmingham).—"Crematorium," meaning the place in which cremation is practised, is a correct, though quite unnecessary coinage. It occurs in no Latin author, and ought to be replaced by the shorter, equally expressive, and quite classical word, "ustrinum."

Mr. Armstrong (Newcastle-on-Tyne) will find his letter inserted in our issue of April 10th, p. 715.

Mr. Lawson Tait's paper will appear very shortly.

A CASE OF AMNESIC APHASIA.

To the Editor of THE LANCET.

SIR,—The following case of amnesic aphasia (uncomplicated) may be of interest.

B. D——, aged fifty-nine, in February last suddenly lost the power of expressing his thoughts in words. On seeing him the following morning, he referred an acute pain to the left temporal region; there was no paralysis of any muscles, and the eyes were both normal in all respects. On examination, a mitral systolic murmur was detected; he also suffered from chronic dyspepsia; the other organs were all healthy. His vocabulary consisted of a few monosyllabic words; he was also unable to read, write, or use figures. He could, however, make himself understood by signs, though the few words he used had no reference to those signs. He was kept quiet and treated with bromide of potassium. Since that time he has greatly improved; he can now talk fairly well when not excited or exhausted; he reads the newspaper, but cannot articulate long or use common words; he can write and add up figures in the course of his business, but is utterly powerless to remember the names of people or places, and still complains of headache. The pain in the left temporal region is doubtless referable to lesion of the convolution of Broca; while from the researches of Dr. Hughlings Jackson it seems highly probable that the injury was caused by plugging of the middle cerebral artery of the left side by an embolus derived from valvular disease of the heart.—I am, Sir, yours truly,

Kendal, May 4th, 1886. R. W. LEEMING, B.A., M.B. Cantab., &c.

PERIODICAL VARIATIONS IN ATMOSPHERIC BACTERIA.

M. MIQUEL stated at the last session of the Paris Society of Public Medicine that in a series of observations he had made on the periodical variations of atmospheric bacteria he found the maximum number occurred between six and nine o'clock in the morning, and the minimum about two o'clock in the afternoon. A second maximum occurred about seven o'clock in the evening, and a second minimum at two o'clock in the morning. The maximum was greater in the town than in the country. The practical advice to which his experiments point is to ventilate one's rooms, more particularly early in the afternoon and in the middle of the night.

Poison.—Vide THE LANCET, vol. ii., 1885, pp. 863, 996, 1070, 1119, and 1167. See also Martindale's little book on Coca and Cocaine.

TEREBENE RASH.

To the Editor of THE LANCET.

SIR,—The following case, which recently came under my observation, ought, I think, to be placed on record.

John K——, aged sixty, was ordered to take five-minim doses of terebene four times a day for chronic bronchitis, from which he has suffered for many years. After taking six doses of the medicine (thirty drops in all), he had to desist, on account of a profuse bright-red, papular rash, intensely itchy, making its appearance, first on the left hand, and then on both ankles, extending up the legs to the knees. The hand was likewise very much swollen. That this condition was due to the terebene was proved by the retrogression of the eruption coinciding with the discontinuance of the medicine. This idiosyncrasy, the patient informed me, was observed about thirty years ago, when, having sprained his wrist, he was recommended to apply turpentine as a liniment. The result of this was the appearance of an eruption of similar character to the foregoing, his arm becoming at the same time so swollen as to incapacitate him for work for a whole fortnight. With the exception of the skin trouble, no other inconvenience has ever arisen from the use of the drug.

I am, Sir, yours truly,

ORMOND H. GARLAND, M.B., M.R.C.P. Ed.,
May 15th, 1886. Hon. Physician to Leith Hospital, &c.

Dr. Unna (Hamburg).—A short article on the subject would be accepted.

Mr. Maddock should apply to the Secretary to the Board.

Mr. Clemow (Lynton).—Yes.

"THE USE OF COCAINE IN OPERATIONS FOR PILES."

To the Editor of THE LANCET.

SIR,—With reference to Dr. Pritchard's claim for priority in the use of cocaine for operations on piles (THE LANCET, March 13th, p. 527), allow me to state that on Dec. 26th, 1885, I used a 4 per cent. solution in the removal of an external pile from a negro, with good result. Earlier in the same day I had occasion to have an abscess in the back of my own neck opened, so asked a medical friend to paint the skin with some of the same solution before making the incision. Beyond a slight scratching, I experienced no sensation as the knife divided the skin.

I am, Sir, yours truly,

BEAVEN RAKE, M.D. Lond.,
April 27th, 1886. Government Medical Officer, Trinidad.

Dr. B. W. Jones (Vulcan, Mich.).—The name and address of the patentees are given in the notice of the apparatus.

Subscriber.—Will our correspondent kindly repeat his questions.

"HOSPITAL ETIQUETTE."

To the Editor of THE LANCET.

SIR,—In fairness to the matron, your correspondent, "M.B. Edin.," ought to quote the rules for house-surgeon and matron of his infirmary. Trained or not, the committee appointed this lady upon certain conditions, and before accepting office the house-surgeon ought to have thoroughly understood these rules. Instead of sheltering himself under your pages, and thus holding the matron up to public ridicule, he should have laid the matter before his committee. The rules of metropolitan hospitals and provincial infirmaries are two very different matters.

I am, Sir, yours truly,

May 15th, 1886. INTERESTED.

A Young Practitioner has not enclosed his card.

Mr. F. Treves.—In an early number.

RINGWORM IN A NEW-BORN INFANT.

To the Editor of THE LANCET.

SIR,—In reference to the two instances cited in THE LANCET of ringworm in new-born infants, I may also add my quota to the cases of your correspondents. On April 13th I attended a young woman in her confinement, and a few days afterwards the nurse drew my attention to a small ringworm, about the size of a sixpenny-piece, on the scalp. One application of tincture of muriate of iron cured it. I may say that tincture of muriate of iron is almost a specific in ringworm.

I am, Sir, yours faithfully,

York, May 19th, 1886. T. CAMPBELL MACCORMAC (Student).

NEWSPAPERS AND PERIODICALS OF JAPAN.

FROM some recently-published statistics of the Japanese press it appears that thirty-seven publications are devoted to matters connected with education, and that these have a total circulation of 42,649 per month. There are seven medical papers, with a monthly circulation of 13,514; nine relating to sanitary matters, with a circulation of 8195, and two on pharmacy. There are seven devoted to various branches of science, with a circulation of 2428; but to these must be added twenty-two engaged in popularising science, with a total circulation of 70,660.

Dr. Murphy (Sunderland).—Yes, soon.

"INFANT FEEDING: COD-LIVER OIL."

To the Editor of THE LANCET.

SIR,—In reference to Mr. S. Yeldham's letter in your issue of May 1st, recommending the administration of cod-liver oil in small quantities to infants to whom no kind of artificial food is of benefit, I wish to say that I have for some time been in the habit of ordering cod-liver oil in such cases by merely floating it on the milk. But since having seen Mr. Yeldham's letter, I have adopted his method, which is certainly most useful and entirely successful.—I am, Sir, yours truly,

St. Mary Cray, May 15th, 1886. EDGAR D. CANE.

THE MALLING UNION.

OUR attention has been called to the way in which the vacancy in the No. 1 district of the Malling Union, caused by the resignation of the medical officer who formerly held the post, has recently been filled up. If the facts are as stated by our correspondent, we have no hesitation in saying that he has just cause of complaint, and we are not surprised that the Central Board has thus far declined to confirm the appointment.

Mr. W. O. Allison (New York).—We cannot exchange.

"SANITARY WOOLLEN CLOTHING AND BEDDING."

To the Editor of THE LANCET.

SIR,—In your issue of May 1st you inserted a letter from me under the above heading, since which I have had almost daily inquiries asking me where the book, "Health Culture," and the articles referred to are to be obtained. Possibly you may allow me to say that the book (price 1s.) and all pertaining thereto may be had of the Dr. Jaeger Sanitary Woollen Clothing Co., Fore-street, London, E.C.

I am, Sir, yours faithfully,

St. Leonards-on-Sea, May 13th, 1886. JOHN PENHALL.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Gowers, London; Dr. A. K. Chalmers, Mossend; Mr. H. D. Cane, St. Mary Cray; Dr. Chepmell, London; Dr. Caddy, London; Mr. W. H. Clinical Lectures
ON
CASES OF DIFFICULT DIAGNOSIS.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE VI.

ON FÆCAL ABSCESSES CONNECTED WITH THE SMALL INTESTINES.

GENTLEMEN,—In a former lecture we discussed the subject of fæcal abscesses arising from ulceration of the colon, and we found it was necessary to consider them separately from those connected with the small intestines, on account of the great difference in the structure, functions, and anatomical relations of these sections of the digestive tube. I now wish to direct your attention to abscesses connected with the other portions of the intestinal canal, but it will be necessary to examine those of the duodenum separately, as this part differs in many important particulars from the rest of the small intestines.

When it is considered how often we meet with perforation of the ileum in post-mortem examinations, we should expect frequently to find an abscess connected with this part; but such is by no means the case. It not unfrequently happens, indeed, that in tubercular peritonitis two or more loops of intestine are united by adhesions, which wall in a collection of pus communicating with the interior of the gut; but as in such instances there is rarely any external tumour, and there are no symptoms differing from those of an ordinary case of tubercular peritonitis, we shall at present reject these and direct our attention only to those cases in which there are symptoms or physical signs that would enable us to suspect the existence of an abscess. On examining the post-mortem records of this hospital, I have met with five such cases of fæcal abscess connected with the small intestines, and I have been able to collect from various authors twenty-five others in which the presence of an abdominal tumour produced by this affection had been remarked during life, and in which a detailed account is given of the appearances discovered after death. It is not, however, difficult to explain the rarity of fæcal abscess connected with the small intestines, for their mobility, the rapidity with which ulceration proceeds in them, and the liquid nature of their contents are sufficient to point out why a general rather than a local inflammation should usually follow perforation of their coats.

When we analyse the cases I have collected, we find that the numbers resulting from the various conditions capable of producing fæcal abscesses are very different from those we before met with when we examined the same affection as connected with the large intestine. Thus three commenced in inflammation around the pelvic organs, which had ended in suppuration, bursting into the lower part of the small intestines, and in all of them there was general peritonitis, in addition to the adhesions surrounding the abscess. In one, which occurred in this hospital, the small intestines had been perforated by an abscess which seemed to have originated in an ulceration of the colon produced by dysentery. In another in our records there was a tumour the size of a child's head connected with the lower part of the ileum; the walls were one inch thick and composed of a cancerous growth, the coats of the intestine being completely destroyed and the two ends of the healthy portions of the gut being continuous with the fæcal cavity thus formed. In a third in our records a very rare condition was discovered: the coils of the jejunum were united by adhesions; their contents had escaped from an opening between them; but the cause of the perforation was found to be the distension produced by a narrowing of the ileum resulting from a small tumour that projected into the cavity of the intestine.

In eight out of twenty-five cases the fæcal abscess had followed an injury to the abdomen. There can be little doubt that this proportion is in excess of what it would be if every case of fæcal abscess had been recorded, but cases produced by accident are especially apt to be noted, as the symptoms are from the first usually well marked, and immediately follow the injury. As this part of our subject is of great practical importance, and has scarcely received the amount of attention it deserves, it will be advisable for us to consider for a few minutes the various ways in which an injury is capable of producing ulceration of the small intestine.

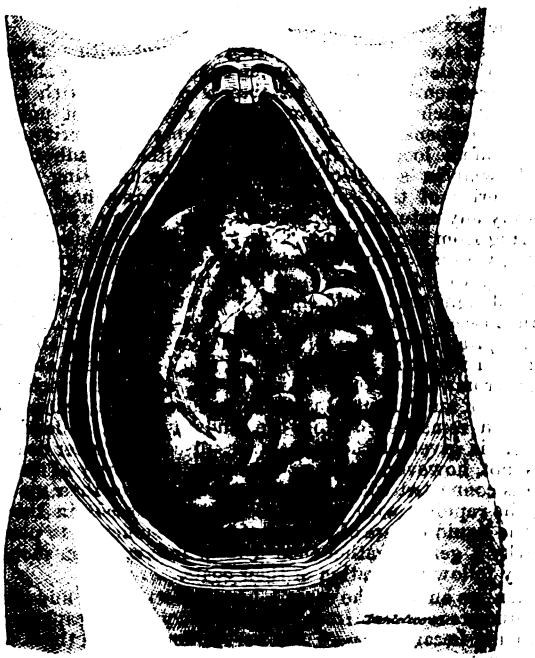
In the first place, then, a blow on the abdomen often sets up either general or local peritonitis, which may terminate by adhesions of some of the loops of the intestine to each other and to the abdominal parietes, these loops being apt to be bent at angles more or less acute. It is at these sharp bends that ulceration often commences, and if it should proceed slowly a fæcal abscess may result. General adhesions were mentioned in six out of eight cases in which the abscess had resulted from injuries; and in five out of the twenty-five cases of fæcal abscess it is recorded that the perforation took place at an angle of a portion of gut fixed by adhesion; this occurred not only when inflammation had followed the receipt of injuries, but also in tubercular peritonitis, and in two instances where there had been only a local non-tubercular inflammation of the peritoneum. It is not difficult to explain why a portion of gut sharply bent by adhesions should be more liable to ulceration than when it is in its normal condition, for the flexure must tend to congest its bloodvessels as well as impede the transmission of its contents.

Secondly, a slight blow may set up suppuration in the abdominal walls or in the connective tissue behind the peritoneum, which may open into any part of the canal. A case is mentioned in our records in 1839 where a boy in delicate health received a blow on the abdomen from a schoolfellow, which occasioned inflammation that terminated his life in five days. On post-mortem examination, three abscesses were found behind the peritoneum, which had been the cause of his death. No opening, however, had taken place into the intestine, although we can imagine how easily such an occurrence might have taken place if the patient's life had been prolonged.

Thirdly, in three of the cases a very small opening in the intestine was discovered after death, and it was believed by those who recorded them that the perforations were the result of previous injury. It seems difficult to understand how an opening the size of a shilling, as is mentioned in one instance, could fail to allow of an immediate escape of the intestinal contents, and thus give rise to rapidly fatal peritonitis, unless we assume that the canal was quite empty at the time of the accident. As this would be rarely the case, I think it is more probable that only one of the coats was in the first instance ruptured, and that the perforation of the canal took place at a subsequent period by an extension of the ulcerative process.

Of the twenty-five collected cases, only seven are noted as resulting from a tubercular affection of the peritoneum. Such a proportion is, however, much below what it would have been if all that came under observation had been recorded, for the occurrence of an abscess of this kind in phthisical cases may take place without producing any very marked variation in the symptoms or deterioration in the condition of the patient, and is consequently apt to be looked upon only as an accident of the general disease. Fæcal abscess connected with this portion of the intestinal canal is, however, so generally the result of this cause, that whenever we are able to exclude the effects of accidents and previous peritonitis, we shall be justified in assuming any case that may present itself as probably due to tuberculosis. Tubercular peritonitis, as you are often told, and as you see so frequently exemplified in the wards, presents itself clinically under three forms: in one the onset of the complaint is sudden, its course rapid, and often closely simulates typhoid fever; in the second there are at first the same acute symptoms, but these soon subside, and an affection of the lungs or some other organ becomes the more prominent manifestation of the disease; whilst in the third the symptoms are from the first subacute, and the malady runs a more chronic course. Now it is in this latter form that, according to my experience, fæcal abscess is most apt to take place, for the intestines become generally adherent, and any escape from the canal is liable to be walled in by the neighbouring viscera; and in support of this opinion it may be remarked that in six out of seven of the cases it is stated that there were general adhesions of all parts of the peritoneal cavity. The ulceration may commence either

Digitized by Google



on the mucous membrane or externally. In two of the seven cases ulcerations of the mucous membrane are noted as having been unusually extensive, and in three there were also ulcerations of the colon. Perforation, as has been before mentioned, was found to be most apt to occur at any sharp bend of an adherent loop of the intestine; on the other hand, three are described as having commenced as "encysted peritonitis," the pus having subsequently made its way into the canal. In all cases the walls of the abscess were formed by the adherent viscera or by thickened membranes. In one instance discharge of feculent matter took place at the umbilicus, in another through the obturator foramen; but generally the abscess was only discovered after death.

The earliest symptoms of the cases of fæcal abscess that I have collected varied according to the disease that gave rise to the ulceration of the intestine. For example, a boy was treated in this hospital for typhoid fever, which ran its usual course, and on his recovery he was sent into the country for change of air. Five weeks afterwards he was suddenly attacked with pain in the abdomen, loss of appetite, and constant vomiting, and was readmitted into the hospital, where he died. On post-mortem examination, numerous ulcerations were found in both the small and large intestines, there were also extensive adhesions between the coils, and an abscess containing fæcal matter communicated with one of the adherent loops of the gut. When the abscess resulted from an accident, the first symptoms were pain of the abdomen and vomiting, and in some instances collapse. In tubercular cases pain of the abdomen and vomiting were also the earliest indications of the disease; in one these were attended with rigors.

As in every instance there was general or local peritonitis, the symptoms during the progress of the malady were only indicative of that condition; indeed, a fæcal abscess was rarely suspected during the life of the patient. Vomiting, pain of the abdomen, and tenderness on pressure constituted the most prominent subjects of complaint. In two instances blood was remarked in the stools, and diarrhœa is recorded as having been present in one quarter of the cases. In seven a more or less defined swelling was observed during life; in one a circumscribed tumour is mentioned as being present near the umbilicus, and in another a tumour was noted at the hypogastrium; all of these being cases of tubercular peritonitis. In a case where the ulceration arose from a sharp bend in a loop of intestines produced by adhesions, an abscess presented itself in the thigh and was opened; in another, arising from a similar cause, the pus was discharged at the groin.

I now propose, gentlemen, that we should direct our attention to abscesses connected with the duodenum, and I must first remind you of the differences in the position and relations of this part, as compared with those of the other sections of the small intestine. Instead of having a complete investment of peritoneum, its second and third divisions are only covered by this membrane in front, and are therefore in immediate relation with the connective tissue behind; and, as a result of this arrangement, perforating ulcers may produce abscesses that may burrow in different directions, and may present themselves at a considerable distance from their point of origin. Then again, the duodenum is fixed and surrounded by numerous important organs, such as the liver, gall-bladder, kidney and colon, all of which are liable to acute inflammations, the product of which may discharge itself into this portion of the intestinal canal. I cannot better show the difference between an abscess of this part and those we have been lately considering than by reading to you the notes of a case for which I am indebted to the kindness of my friend and colleague, Mr. Rivington.

CASE I.—William C——, aged nineteen, plasterer, was admitted under the care of Mr. Rivington on Nov. 1st, 1881. In the afternoon he had fallen upon his abdomen from a height of 12 ft.; he was picked up by his fellow-workmen and carried home. He vomited everything he took, and was brought to the hospital the same evening. Very little history of his previous state of health could be obtained, but it was stated by his friends that he had been drinking heavily for some time, and that the vomiting had commenced two days before the accident. He had, on admission, a pinched and anxious face, pulse very feeble, skin hot and bathed with perspiration, and he complained of slight pain in the hypogastric region; temperature 100·4°. He made no complaint of any severe pain. On Nov. 3rd the pain was localised to the right inguinal region; bowels confined. On the 7th he was very restless, and had fixed pain in the right inguinal region; diarrhœa for two days. On the 15th he seemed to be in a typhoid condition; fulness was noticed in the right inguinal region, and there was some dulness there on percussion. On the 18th there was a distinct fulness close to the pubes in the right inguinal region, which was hot and tender; the stools were formed, but offensive. He gradually improved after this date, and left the hospital on Dec. 24th. His temperature varied between 100° and 103° until Nov. 21st, after which it rose every evening to 102°, falling in the morning to the normal point. He was readmitted on Feb. 1st, 1882. He was then somewhat emaciated, his cheeks thin and flushed, and his expression anxious. There was a hard swelling in the right groin above and to the right of Poupart's ligament, which fluctuated with an emphysematous crackling, as if air and fluid were intermixed; bowels opened daily. He had little pain or tenderness over the abdomen. On the 10th an incision was made into the tumour, and a large quantity of yellowish feculent pus was evacuated. On the 27th the discharge was feculent and profuse, and pressure on any part of the abdomen caused a large quantity to be evacuated. On June 14th the sinus was more freely opened, and a large amount of fæcal matter removed. On the 28th diarrhœa came on, and he became much weaker. He lingered until July 31st, when he sank from exhaustion, nine months after the receipt

Sketch of Mr. Rivington's case of Peri-duodenal Abscess.

of the accident. The temperature always rose in the evening to 101° or 102°, and generally fell to the normal point in the morning.

Post-mortem Examination.—The body was so much wasted that it looked as if the patient had died of starvation. On opening the abdomen, a channel was discovered extending from the under surface of the liver to Poupart's ligament on the right side; it was situated behind the ascending colon, and was about two and a half inches wide. The roof and inner wall were formed of thickened peritoneum and the adhering gut, the floor by the thickened fascia covering the quadratus lumborum and the ileo-psoas, the outer wall by the thickened transversalis fascia, and there was a free opening at Poupart's ligament where was a fæcal-stained cavity, supposed, at first sight, to be formed of the gut adhering to the abdominal wall. The lower horizontal limb of the channel ran behind the pubes and formed a slightly sacculated end in the left groin. The channel contained no solid fæces, but its walls were coated with a brownish-yellow fæcal deposit. As it was supposed there might be some connexion with the intestines, water was injected into the colon and into the small intestines, but none escaped until it reached the duodenum, from which part it flowed out in a large stream into the upper extremity of the channel and swept downwards to Poupart's ligament. At the point of

Digitized by Google

escape the duodenum presented an ulceration the size of a sixpence, with thickened edges, about five inches and a half from the pylorus, which had perforated all the coats and communicated with the channel. All the other organs of the body were healthy. (See Figure.)

In this very interesting case it is impossible to determine, from the want of a proper history of the condition of the patient before the injury, if there had been previously an ulcer of the duodenum; but whether such was the case or not, it is evident that the intestine was ruptured by the fall. The accident occurred at three in the afternoon, two or three hours after the usual dinner-hour of the labouring class, when the duodenum would be probably distended by the products of the gastric digestion, and therefore most liable to suffer from a severe blow. The vomiting and partial collapse in which he was found on his admission into the hospital pointed to some grave injury of the abdominal organs, whilst the complaint of pain in the right groin at that time seems to prove that the intestinal contents had already found their way into and down the connective tissue behind the peritoneum. This conclusion is supported by a very similar case described by Mr. George Pollock.

CASE 2.—"A young man was admitted into St. George's Hospital with symptoms of ruptured intestine, but somewhat less prominently marked than is usually observed when such an injury has occurred, so much so that we hesitated to give a positive opinion as to the exact amount or situation of the mischief. Under treatment for a few days he seemed to improve. Then worse symptoms set in, and he died twelve days after the accident. The duodenum was found lacerated behind the peritoneum. Its contents had escaped and had set up suppuration, which had travelled down in front of the right kidney behind the peritoneum, as low as the right iliac fossa."[1]

These cases are most valuable, not only in proving that injuries of the small intestines may, under certain circumstances, perhaps end in recovery, but also in showing that the part to which the pain is referred may be at a great distance from the actual site of the lesion. In both suppuration was established in the connective tissue behind the peritoneum; and in Mr. Rivington's case an abscess presented itself in the neighbourhood of the bladder, and was opened in the groin.

I have, gentlemen, in previous lectures, prefaced the consideration of each subject with one or two cases which might serve as illustrations of the usual course of the disease we were discussing, but on the present occasion I have departed from this plan. The two examples I have just quoted are intended to show the differences that may exist between abscess connected with the duodenum and those of other parts of the small intestine, but cases of this sort are so extremely rare that you are not likely yourselves to encounter them. In the course of my reading I have not met with any others precisely similar as regards the length of time the patient lived after the accident, or where the symptoms of suppuration of the connective tissue so rapidly followed the injury.

When examining the abscesses that are connected with the other portions of the small intestines, we found they were most frequently due to tubercular disease, but this does not seem to be the case with respect to those of the duodenum. In our post-mortem records I have only been able to discover five instances of peri-duodenal abscess; in three the mischief had been caused by the perforation of duodenal ulcers, in one by suppuration set up by an impacted gall-stone, and in one by tubercular disease of the kidney, which had produced a perinephritic abscess that burst into the duodenum. I have collected twenty-nine cases (including the above) from various authors, and of these eighteen originated in ulcers of the duodenum, three in chronic ulcers of the stomach, five in suppuration in the neighbourhood of the gall-bladder, and one in what was believed to have been an old hydatid cyst of the liver.

Let us, in the first place, examine the cases that have arisen from ulceration in the duodenum itself. You are aware that the stomach differs from the other parts of the digestive tube in its greater liability to the "round," or, as it is often termed, the "perforating" ulcer; and the mucous membrane of the duodenum also presents instances of the same kind of lesion. It is, however, much more rare, for only five post-mortem examinations of duodenal ulcer are recorded in our books during a period in which there are noted sixty-nine fatal cases of gastric ulcer. The usual site in the cases I have collected of the ulcers producing abscess was in the superior portion of the duodenum, where it is covered, like the stomach, by peritoneum; for of ten, eight are stated to have been situated in this locality, one was in the descending and one in the transverse portion; in the remainder the site is not stated. This greater liability of the superior portion you must not refer to a greater tendency there to the production of abscess, for it is the part that is most subject to ulcerations; thus, Kraus states that of sixteen cases of perforating duodenal ulcer he had collected, twelve were situated in this part of the gut. It would appear that acute ulcers are but little apt to set up abscess, as they generally destroy life either by hæmorrhage or by perforation into the cavity of the peritoneum, for in only one instance of those I have collected are the edges stated to have been sharp; in all the others they are described as "round" or "thickened." The materials forming the walls of the abscess varied greatly; thus, in ten out of eighteen they were formed by the adhesion of some of the neighbouring viscera, in two the pus was contained in a cavity in the substance of the pancreas, and in five suppuration had taken place in the connective tissue behind the intestine, and had spread from that part in different directions. In most instances it is worthy of notice that the abscess might have been safely reached by a surgical operation.

It is a common remark that no important part of the animal frame can become the seat of disease without other organs being also affected, and abscesses arising from ulcerations of the duodenum present no exception to this rule. In one out of eighteen the duodenum is said to have been dilated, in two its calibre was contracted, in five the stomach was found to be greatly dilated, and in two the spleen was much enlarged. The dilatation of the stomach is, I suspect, a much more frequent accompaniment of chronic duodenal ulcer than might be supposed from these figures, and may be a useful sign in the diagnosis of such cases. In only two a tubercular condition of the lungs is mentioned. In five instances the abscess originated in the neighbourhood of the gall-bladder, and afterwards burst into the duodenum. In each case it seems to have been the result of irritation set up by gall-stones, but in one concretions could not be discovered, although the ducts were greatly dilated, pointing to the previous existence of some obstruction to the free exit of the bile. The exact place at which the pus had been discharged into the intestine is only mentioned in two cases; in one it was into the superior and in the other into the descending portion. In all the sac was formed by adhesions, and no case is recorded in which suppuration was set up in the connective tissue. This is of course what might have been expected, as the abscess in most cases originates in suppuration of the gall-bladder itself. In two instances the abscess was situated at a little distance from the duodenum, and opened into it by means of a sinus. In one the abscess was produced by the irritation of a malignant tumour that involved the gall-bladder and ducts, but no mention is made of the presence of a calculus.

The cases I have collected throw but little light upon the causation of duodenal abscess. Of course when they originated from gall-stones, hydatid cysts, or perinephritic abscesses, it is easy to account for them, but what we are chiefly concerned with is to ascertain what circumstances tend to produce the chronic ulcers of the gut that by perforation of the intestinal walls usually give rise to them. Statistical inquiries have proved that duodenal ulcers are most common in the male sex, and chiefly occur between thirty and fifty years of age. Now, of eleven cases of duodenal abscess, nine were males and only two females; and only one occurred below twenty years of age, four between thirty and fifty, and three above fifty years of age. In all probability, ulcers in this, as in other parts of the gastro-intestinal tract, are most apt to perforate rapidly in the young, and it is only as age advances that there is a tendency to a slow process of ulceration, and consequently to the formation of adhesions and abscess around the gut. As duodenal abscesses may arise from so many different causes, it is evident that the symptoms and course of the disease must vary accordingly. Let us, then, first consider the cases that have been recorded as having resulted from simple ulcers in this portion of the intestinal canal. I have been able to collect only fourteen of this class in which a

[1] Holmes's System of Surgery, vol. i., p. 878.

Digitized by Google

history of the symptoms is given, and in some of them the details are unfortunately very scanty. They were all of long duration; thus, in one the symptoms of ulcer had existed for eight, in another for seven, in a third for three years, and in one for twelve months, whilst in three they are mentioned as having been present for "a long time." You will remember that we before found the ulcerations after death were always stated to have had thick or round edges, so that there is no doubt the quickly spreading ulcers destroy death rapidly, and it is only in such that have been long in a quiescent state that external adhesions occur and the formation of an abscess becomes possible. In all of the cases the patients had previously enjoyed good health, with the exception of one who had suffered from cough and slight hæmoptysis, and in whom, after death, emphysema of the lungs was found. Pain was the prominent symptom in the majority of the cases; in some it came on one hour or at a later period after food, in others it occurred occasionally, the patient being free from suffering in the intervals. In one instance it was looked upon as neuralgia of the cœliac plexus; in another the pain is described as radiating from the epigastrium to the right hip. In two cases there was no complaint of pain, but only a sensation of fulness after eating, until at last more severe symptoms suddenly made their appearance. Vomiting was present in most of the cases, but was by no means so general a symptom as pain. Usually the food last taken was alone rejected, with immediate relief of the pain, but in one case the fluid was intensely sour and the stomach was found after death to be much dilated. In the majority there was either hæmatemesis or blood was passed from the bowels. In some this occurred frequently, in others only once, but it was usually profuse, and in one the blood is mentioned as having been passed in dark clots. Loss of flesh was a prominent symptom in all the cases, and ulceration in this locality seems to produce a more marked effect on the general health than when the stomach only is affected. Want of appetite is not especially noted, but in one patient it is stated that the appetite continued good until near the termination of the illness, when it quite disappeared. Paleness of the skin is generally recorded as having been present; some are described as "anæmic," others as "earthy-coloured," and some were "like persons suffering from cancer." No doubt this anæmia arose partially from the hæmorrhages to which the patients were liable, but it must also be attributed to the disturbance of nutrition resulting from the ulceration. The cases as a rule, after continuing for a length of time, terminated suddenly. In only one the duration of the final attack was three weeks, when the patient died of pleurisy. Most of them were carried off by hæmatemesis or by perforation of the peritoneum, three sank from exhaustion, and one died of suppuration of the lungs and of the parotid gland. You would of course expect to find considerable differences in the symptoms and course of a duodenal abscess when this originated from irritation of the biliary passages, and when it was the result of a duodenal ulcer. I cannot show the distinction more clearly than by quoting the following case from our post-mortem records.

CASE 3.—A man, thirty-five years of age, had been affected with jaundice four years before his admission into the hospital. He stated that it had come on very gradually, and had lasted without intermission for nearly three years. At the end of this time he was attacked with a severe pain of the left side and across the abdomen, and on the subsidence of this the jaundice gradually disappeared. Five weeks before his admission he had a severe rigor, followed by delirium. When admitted he was suffering from jaundice, and a mass could be felt occupying the right side of the epigastrium, which seemed more clearly defined than would have been the case if it had consisted of an enlargement of the liver. The left lobe could be felt projecting below the ribs; the mass moved with the respiration, but the gall-bladder could not be distinguished. Four days after his admission he is stated to have had no pain, the stools were natural in colour, but he had been sick and had vomited. On the sixth day he had severe rigors followed by sweatings, the temperature reaching 103·4°; and severe rigors occurred again on the eighth day. On the tenth day jaundice was remarked as still remaining, and there were repeated rigors on the twelfth day. On the fifteenth day he complained of a peculiar sensation at the epigastrium, and brought up a quantity of dark-coloured blood. On the following day he suffered severe pain in the epigastrium, and rapidly sank. At the post-mortem examination, a gall-stone, the size of a filbert, was found to be impacted in the common duct; the gall-bladder was destroyed by suppuration, and a large sinus extended between the gall-bladder and the duodenum, which were united together along with the liver, in the substance of which were numerous abscesses; there was also an abscess deeply placed in front of the left kidney.

Now the first point that will strike you is that up to five weeks before the patient's illness he was in good health, for this is a marked difference from the long-standing pain, vomiting, and emaciation we before found in persons who were affected with an abscess produced by ulceration of the mucous membrane of the duodenum. There was also a history of chronic jaundice, from which he had recovered; and attacks of colic or of jaundice are also recorded as having been present in other cases of a similar nature I have been able to collect. A sudden onset had also been observed in them as in the foregoing case, and was no doubt dependent on the mischief set up by the irritation of biliary calculi. Repeated rigors did not constitute a prominent symptom in the former class of cases, but in that just related it was probably dependent on the formation of the hepatic abscesses discovered on post-mortem examination. In duodenal abscess arising from internal ulceration, hæmatemesis or the passage of blood by stool was one of the symptoms most commonly remarked, and I have also found one or other of these in almost all the cases I have been able to collect where the abscess had resulted from irritation of the biliary passages.

As regards physical signs, I have only been able to collect nine cases in which these are given with sufficient detail to allow of definite conclusions being drawn from them, and it should be borne in mind that a swelling is not likely to be detected when the abscess is situated very deeply, and that a tumour may, as we have before seen, present itself at a considerable distance from the duodenum when suppuration has extended into the connective tissue. A tumour was discovered in the epigastrium, or region of the liver, in seven out of the nine cases; in one it was situated in the right iliac region, and in one at the back of the right shoulder. It was mentioned as being visible in only three cases, but in all probability this point may have been omitted in the records of many others. It was "hard" in three, and "soft" or "elastic" in two. The note on percussion was "tympanitic" in four cases, and in one a metallic sound was produced by the shaking of the patient. In one the liver and heart are stated to have been displaced upwards by the large size of the tumour. Alterations in the percussion note are noticed in only one case, and in this it is said that the tumour remained fixed on full inspiration, but that the line of dulness varied according to the position of the patient. In one only is it mentioned that the contents of the tumour were influenced by the action of the intestines, the note on percussion being much clearer when diarrhœa was present. In some of the abscesses in which there is a communication with the duodenum, physical signs present themselves closely simulating those of pneumothorax, but we must defer their consideration until we examine the subject of abscesses connected with the stomach.

I need scarcely say that the diagnosis of an abscess connected with the duodenum must be a matter of great difficulty on account of the various conditions which may give rise to it, the different directions the pus may follow, and the great depth at which this portion of the intestinal canal is situated. But, in addition to this, it is very difficult to make out the exact limits or even the existence of a painful tumour situated in this locality, for the patient usually contracts his muscles directly pressure is made over it, so that they become as hard and unyielding as a board. When, however, you have been able to satisfy yourself of the presence of a tumour, you have to consider whether it is an abscess, carcinoma of the liver, stomach, or peritoneum, or perhaps only a fæcal accumulation.

In the first place, then, you must bear in mind that an abscess connected with the duodenum is, as we have before found, almost always the result of a very chronic ulceration of the gut, or of the irritation set up by gall-stones. In the former case, the patient will have suffered for many months or years from pain after food or from severe attacks of pain attended by vomiting, or from profuse hæmatemesis or the passage of blood by stool. In cancer the progress of the case is much more rapid, the patient seldom living more than nine or twelve months after its commencement; the pain is more constant; the anæmia and emaciation more

Digitized by Google

marked; the hæmatemesis, if present, more frequent and smaller in amount. In abscess near the gall-bladder the onset of the symptoms is sudden, the progress rapid, and there is usually a history of colic or of jaundice. In abscess from either cause the temperature is high, whilst in cancer it is often below the normal point. The tumour in duodenal abscess is less defined and more tender than in cancer, and percussion often affords a tympanitic note or a splash, as if the contents were composed of liquid and of gas, or, in other cases, the line of dulness varies with the position of the patient. In the case of fæcal accumulation the temperature is not elevated; there is a history of constipation; the tumour is dull on percussion, and when firmly pressed upon it seems to give way before the fingers, as though an indentation were thereby produced in its substance. When an abscess has commenced in the peritoneum, and afterwards burst into the gut, you will find, in addition to the signs of a tumour filled with gas or fluid, a history of diarrhœa and localised pain accompanied by fever, the temperature remains high, and the auscultation and percussion usually afford evidences of a tubercular condition of the lungs. We will defer our consideration of the treatment of these cases until we discuss the subject of abscesses connected with the stomach.

ON THE

REMOVAL OF DEEP-SEATED TUMOURS OF THE NECK.

By ARTHUR E. BARKER, F.R.C.S.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL, AND TEACHER OF PRACTICAL SURGERY AT UNIVERSITY COLLEGE.

IN THE LANCET for Jan. 30th of this year I ventured, under the above heading, to put forward some conclusions which appeared to me justified by a considerable recent experience, and which seemed to me not unworthy of note as bearing upon a question constantly cropping up in the experience of every practitioner—namely, what can be done for deep-seated tumours of the neck? Since the cases then recorded were operated on, others have come under my care which have strengthened the opinion there expressed, but none so much as the last. This involved the deepest and widest dissection I have ever made in the neck, and was, nevertheless, as complete an enucleation of a distinctly encapsuled growth as one could wish. It was accompanied by very little bleeding, and no important structures were divided. Again, the very extensive wound healed from bottom to surface everywhere by first intention, except in the track of the drainage-tube, and here only a drachm or two of thick serum was found every three or four days until it had closed, the patient suffering nothing from the wound, either locally or constitutionally, all the time. The following brief record of the case speaks for itself, and emphasises the conclusions in my first paper perhaps more strongly than the cases there narrated.

T. H——, aged sixty-four, a labourer from Cornwall, was admitted into University College Hospital on Feb. 22nd, 1886. His personal and family history were excellent, showing nothing but some rheumatism. He has had a family of six children, all of whom are healthy. Five years ago he felt a little pain in the nape of the neck, and a little later noticed a small lump between the left mastoid process and middle line of the neck behind. This lump appeared to be deep-seated and fixed, and grew very slowly until six months ago, when it began to increase rapidly, attaining double its former size since then. There has been from the first occasional pain in the tumour of a gnawing character and radiating to the back of the head. There is no history of a blow in the region of the swelling, and but an indistinct one of strain. The tumour is described in the hospital notes as reaching from the anterior border of the left sterno-mastoid muscle to the posterior middle line, and from the inferior occipital curved line above for about 4 in. downwards. It is thus 5 in. across and 4 in. vertically. Its upper limit corresponds to the insertion of the splenius capitis and trapezius muscles into the superior curved line. The anterior border of the latter muscle is very prominent below the growth, and can be traced over it for a little distance above. The tumour is very elastic, but does not fluctuate. There is very slight lateral mobility, but none from above downwards. The heart and breath sounds are normal.

Taking the above facts into consideration, together with the sensation of the tumour to the finger and its appearance, I had little doubt that we were dealing with a sarcoma. But the point of its origin, the degree of its limitation, and its exact depth in the neck were matters about which it was impossible to come to any definite conclusion. That it lay very deeply was quite clear, but whether it sprang from the base of the occipital bone, from the spinal column, or lay between the muscles, it was quite impossible to form an opinion. I thought it quite possible, however, that it might be found, on examination of its surface, to be quite separable from surrounding parts in spite of its depth, having been agreeably surprised in this respect in analogous cases more than once. I therefore explained the gravity of the matter to the patient, and that it was quite possible that it would be found to be beyond the reach of excision, but that this could only be determined by making an exploratory incision through the coverings of the tumour. It was pointed out to him that if this exploratory incision revealed the fact that the tumour could not be removed, it could be closed and would heal without any mischief being done. To this alternative the patient readily agreed, and the operation was performed a couple of days later. The preliminary treatment consisted in shaving and washing the whole of the occiput several times with warm water and soap, then with a solution of perchloride of mercury (1 in 500), and finally soaking it with carbolic acid solution (1 in 20).

Operation.—On Feb. 24th, with every antiseptic precaution except the spray, an incision was made, commencing about an inch above the superior curved line of the occipital bone and an inch from the middle line, and running downwards and outwards for about two inches, and then directly downwards for three inches. This was designed to expose the origin of the trapezius and its anterior border. When this muscle and the splenius capitis had been exposed, it was found that the latter was more directly in the way than the trapezius. It was therefore slit upwards in the direction of its fibres nearly to its insertion, and the inner portion thus separated was divided transversely above. On everting this portion, the tumour was well seen, still covered by a very thin layer of muscle fibres derived from the complexus. These were now torn across at their superior attachment to the bone, and the finger was insinuated between the latter and the growth. As the bone appeared quite unimplicated, the finger was carried deeper and deeper until the insertions of the rectus capitis posticus, major and minor, and obliquus superior were reached. Just here I was for a little time uncertain whether the dissection should be proceeded with, but, finding the other aspects of the tumour were quite well defined in a capsule, I continued its separation from the small rotators until the spinous processes and ligamentum nuchæ were reached. The tumour lay directly upon these, and here the attachment was firmest. Some steady clearing with the finger, however, loosened it cleanly, and then it was separated from the transverse process of the "axis," which was commencing to be absorbed by pressure. Lower down it was not at all difficult to isolate it from the complexus and inferior oblique muscles, and it was soon cleared and lifted out. Just at the last, in lifting out the tumour, two small fragments were broken off, each about the size of a flattened pea; these corresponded to a spinous and transverse process. Except at the points where they came away, the capsule was unbroken and well defined, so that every particle of the growth shelled out. It may be said to have lain upon the occipital bone between the superior and inferior curved lines, lower down, directly upon the four short rotators of the skull on the left side from their origins to their insertions; the ligamentum nuchæ and interspinous ligaments were pushed over to the right by it, and the splenius capitis and trachelo-mastoid to the left, while the body of the growth corresponded to the bulky part of the complexus at its upper end. Part of this muscle was expanded over the growth posteriorly, and over this again was stretched the trapezius. Apparently, then, the mass grew from or beneath the under surface of the complexus. The only vessels distinctly troublesome were found in the upper angle of the scalp wound, where the branches of the occipital were divided and required ligature. Besides these, some few muscular twigs were closed by forcipressure, and one or two venous twigs in the deeper part of the wound. The total loss of blood probably did not exceed four ounces, most of it being

Digitized by Google

derived from muscular oozing. The field of operation, having been dried out, was dusted lightly within and without with iodoform, and was closed with five silk sutures, a drainage-tube being left in the lower angle, reaching about four inches down to the small rotators. Strips of salicylic wool were then laid on either side of the incision, and others across these, until a thick even covering enveloped the whole occiput. Then a large quantity of ordinary wool was carried over this and under the chin, and was firmly bandaged so as to support the head on all sides and prevent movement, as well as to exercise elastic pressure on the large wound and bring all its surfaces into contact. Over this a kind of cuirass reaching from the waist to the occiput, consisting of poroplastin moulded beforehand to the body, was applied, and the shoulders and head were further immobilised by bandaging to it.

The patient bore the operation well, and after a rather restless night became quiet. He was inclined to become restless again, but this was probably due to his disposition, otherwise his state was very satisfactory, and he slept well, as a rule, after a little morphia. The temperature rose on the third night to 101·4°, the night following to 101·6°, but on the next night only rose to 100°, and remained below this figure for the rest of convalescence. The wound was dressed for the first time on the fifth day, and was found quite quiet, without a trace of discharge. The drainage-tube was withdrawn, cleared of blood-clot, shortened to about two inches, and replaced. The same form of dressing as before was applied. Two days later it was examined for the second time, and the tube was removed for good, as only a little thick serum was found. It was dressed as before. Four days later the wound was dressed for the third time. It was found united everywhere by first intention, except where the drainage-tube had been inserted. Here about a drachm and a half of thick odourless serum had exuded. The stitches were all removed and the same dressing was reapplied. After the next dressing, which was two days later, there is nothing to note, only one small spot remaining unhealed at the time. The patient was out of bed on the twelfth day, and each day until he left hospital on the seventeenth day. For about a week before leaving he had complained of severe rheumatic pain in the right arm, probably due to the cold March weather, when he began to sit up after lying wrapped in wool. This was improving when he left for Cornwall. At this time he seemed almost to have forgotten his old trouble in the neck, but made a good deal of his rheumatism. The microscopical examination of the tumour showed it to be a myxo-sarcoma. From a letter received lately from the patient's medical man in Cornwall, I learn that the result of the operation is most satisfactory.

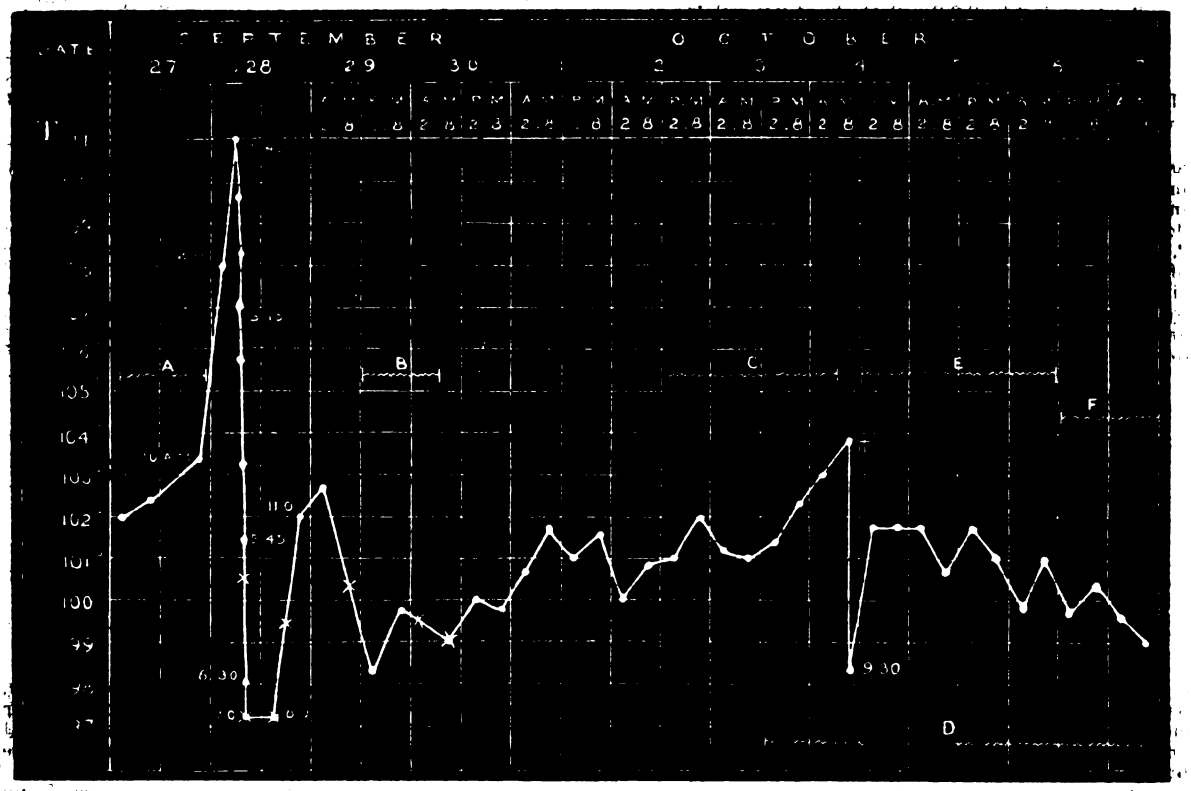
A CASE OF

RHEUMATIC HYPERPYREXIA, WITH NERVOUS SEQUELÆ, SIMULATING MULTIPLE SCLEROSIS.

BY ARTHUR FOXWELL, B.A., M.B. CANTAB.,
ASSISTANT-PHYSICIAN (LATE RESIDENT MEDICAL OFFICER) TO THE GENERAL HOSPITAL, BIRMINGHAM.

ON the evening of Sept. 27th, 1884, I admitted W. J. S——, aged thirty-three, married, sadler, into the General Hospital, under the care of Dr. Russell. He was one of a family of fourteen, twelve of whom were alive and well. His father was sixty-four years of age, and healthy; his mother died of "consumption of the bowels" at the age of fifty-six. He had lived in Birmingham sixteen years, and had been more subject to colds during this period than formerly, though he was always considered a delicate child. Twice he was attacked with inflammation of the lungs, fifteen and twelve years since respectively. Seven years ago he was unable to do any work for a fortnight on account of "dizziness and dyspepsia." Otherwise his previous history was good. His present illness commenced fourteen days before as a chill with severe pains in all his joints which had obliged him to keep to his bed. On the 25th his wife noticed pimples (sudamina) all over his body. At 6 P.M. on this day he became very hot and half unconscious; he was deaf, but could see; his breathing was noisy and rapid. He remained thus till 3 A.M. on the 26th. At 6 P.M. on this day a similar attack occurred, but only lasted an hour and a half.

My note on admission was as follows: "Well-formed man; body covered with sudamina, and there is a free acid sweat; complains of pain in his joints; the ankles, knees, and wrists have effusion; slight dyspnœa. Heart: area normal; apex a confused repetition of impulses; to the stethoscope sounds are cantering and feeble, with probably a systolic mitral. Lungs, liver, and spleen apparently normal."



Sept. 28th.—10 A.M.: In much less pain, but complains bitterly of thirst. Sordes about the mouth. Temperature higher, 103·2°; pulse 96; respiration 26. I saw him at this time in the course of my morning round, and must confess to having noted nothing beyond a more than usually severe attack of fever, though the lessening of pain should have aroused my suspicions.—Noon: Salicylate of soda (which he had been taking since admission) stopped, because he was slightly deaf and appeared rather light-headed. He had had 140 grains in all. From 2 to 4 P.M. his friends were with him, as it was visiting day. His wife says he answered her questions, but he states that he remembers nothing after the giving out of the dinners at 1 P.M. — 4.15 P.M.: I was sent for, and found him quite unconscious. Pupils contracted and insensitive; skin burning; respiration 90, and noisily stertorous; pulse 200, full and bounding, but beats quite distinct, though tumultuous; temperature in axilla 108°; a loose stool in the bed. — 4.45 P.M.: Immersed in bath at 90°, which was cooled to 70° in fifteen minutes, and then maintained at 70° to 75°; lumps of ice kept floating around his head, which was also completely immersed except nose and mouth.—5.45 P.M.: Removed from bath. During his stay in it the pulse kept good and distinct, though its tension and size much diminished, especially towards the latter part. Towards the end, too, his vocal cords began to act, and he moved as if conscious of pain, although his pupils still remained insensitive; stertor also vanished, and he breathed quietly.

All the temperatures above 105° were taken with two thermometers, whilst the highest (111°) was taken with three. Those from 4.45 P.M. on the 28th to 2 P.M. on the 29th, inclusive, were rectal, the rest axillary. (See accompanying chart.)

Oct. 3rd: Has been in a mental state of very little change—one of dull puzzledom. Sordes and sudamina are gone. Joint effusion has almost entirely vanished, though he still complains of pain. Heart has feeble first sound at apex.—9th: Still in a fog as to time past, though quite clear-headed about the present. Great difficulty in enunciating consonants; intonation is nasal, though the soft palate moves well; speaks slowly and very laboriously. No paresis of any kind noted in limbs. Knees stiff and painful.—13th: Speech better, but still nasal; each word is hung upon; reflex movement of soft palate very deficient, but voluntary movement and localisation good. Pupils large, but react well to light. Knee-jerks normal.—20th: Talks sensibly, but with convalescent childishness. Grasp of hands equal, but feeble; well-marked rhythmic tremors on attempting to bring an index finger to the tip of the nose, these increasing as the hand nears the face. Knee-jerks exaggerated, especially on the right side; ankle-clonus is well marked on the right, slightly so on the left; plantar reflexes normal. Walks too feebly to make out any tremors; there are probably none; he brings his feet down with a helpless flop. Sensation to touch is quite good everywhere. No nystagmus; no contraction of field of vision; no ocular paralysis. Smell and taste good. A primary interrupted current strong enough to produce a moderate contraction on a healthy neighbour acts rather less well on the patient, but all his muscles react equally well.—21st: He measures his words, though not rhythmically. Says "stretsh" for stretch, "clooh" (German *ch*) for clock. Has much difficulty in pronouncing *l*, and the *m* in "many." His lips do not respond actively to the will, the upper being comparatively immobile.—22nd: Less tremor in arms. Articulation is perceptibly scanning to-day.—26th: No rheumatic pains left, but general stiffness in all his joints. Can walk alone, but feebly and with a somewhat ataxic gait. Right leg is the more affected. He has no woolly sensation beneath his feet. Pupils are large and indolent, with some deficiency of accommodation. There is slight nystagmus on extreme rotation out or in. Articulation is tardy and indistinct still;

Digitized by Google

the tongue seems most at fault. - Nov. 5th: Right arm much better; can pick up a pin, but doing so produces tremor. Left arm much the same. Walks very feebly, but lifts his feet well, though he puts them down too abruptly. Walking at once causes giddiness. Speech of same character, but much clearer and less laboured; he stutters occasionally before an *s*. — 25th: Speech still nasal and palate reflex deficient. All his joints are stiff, and he cannot fully extend his knees. His right foot is especially painful. Complains of the tremors in his arms; they prevent him writing his name even when he attempts to do so unobserved. Can walk with his eyes shut.—Dec. 30th: Words are still slurred, and the difficulty with the gutturals and labials continues. Palate reflex is now not deficient; uvula is drawn to right in saying "Ah"; tongue is protruded to left, but withdrawn in either direction; left side of the mouth is rather indolent.

The patient was in a bath one hour: from 4.45 till 5.45. On removal, he was wrapped in a cold pack and an ice-cap applied. At 6.30 the pack was removed, and twenty grains of sulphate of quinine were given. At 7.0 the ice-cap was removed. At 9.0 the ice-cap was reapplied. At 11.0 twenty grains of sulphate of quinine were given. At the times indicated by the crosses (x) he vomited. From admission till noon on the 29th he had seven loose stools; thereafter his bowels were confined, and his average daily excretion of urine from September 29th to October 3rd, inclusive, was thirty-six ounces. At † a cold pack was applied, and continued for an hour and a half.

Line A represents the period during which twenty grains of salicylate of soda were given twice.
Line B " " ten grains of sulphate of quinine were given four times.
Line C " " one grain of sulphate of quinine and ten grains of bromide of potassium were given four times.
Line D " " three ounces of brandy were given daily.
Line E " " six grains of kairin were given every hour.
Line F " " ten grains of salicylate of soda, four grains of carbonate of ammonia, and four minims of tincture of digitalis were given twice.

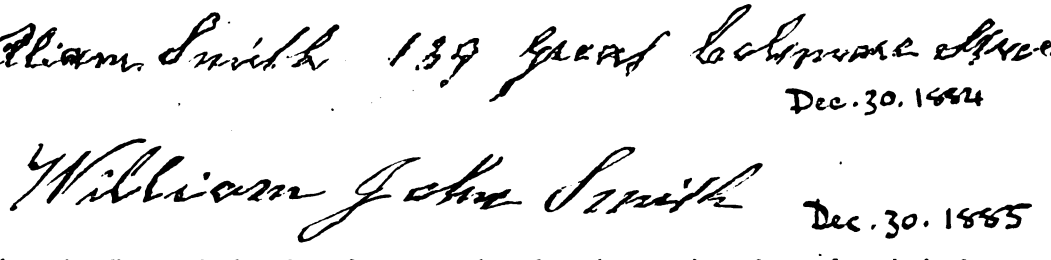
Can walk fairly well, but is still very weak, and trembles all over on exertion; knee-jerk remains much exaggerated; the plantar reflexes are also increased. On attempting to produce ankle-clonus, a regular rhythmical tremor is set up. There is deficient sensation at a spot in front of the right ankle. His grasp is tremulous and feeble.

On Jan. 1st, 1885, he was sent to a convalescent home. As to treatment, he had phosphate of iron, cod-liver oil, and strychnia. His urine on Sept. 28th was as follows: sp. gr. 1020; acid; much urates and uric acid; cloud of albumen; no sugar; granular casts, a few epithelial casts, and some loose epithelium. On the 30th it was: sp. gr. 1030; very acid; urates; very faint cloud of albumen; no sugar or casts. The cloud of albumen remained till the end of October, and then the urine became normal. His heart was unaffected throughout, the murmurous first sound heard during the first week being due no doubt to the pyrexial state.

Dec. 30th.—Has been able to do his work ever since he left the convalescent home in February, though not so well as before his illness. His temperature sense is peculiarly modified. The body generally is less sensitive to changes in the surrounding atmosphere than it used to be; he has no need to be so careful about wrapping himself up, and is less liable to catch cold; has no transitory shiver—e.g., on coming out of his hot shop; is better able, though to a correspondingly less degree, to bear the heat of summer, and he flushes more readily, though the tendency to perspire is unaltered. On the other hand, his perception of hot and cold substances locally is keener; a hot plate feels considerably hotter than before, this being especially the case with the left hand. This left hand is also more sensitive to cold (e.g., snow) than it used to be, whereas in the right he detects no change in this sensation. [Thus the right hand and left leg are, in all the variations noted, less affected than the left hand and right leg.] He does not seem to perceive the sensation more *speedily* than usual, but when it is perceived the sensation is stronger. Pen-points less than one-eighth of an inch apart on the finger-pulps are felt as one, the pulps being no more sensitive than the rest of the fingers [the skin of the finger-pulps is very horny]; on the dorsum of the feet points less than one inch apart are felt as one. The front of the right ankle still feels numb. Localisation of one point is quite correct. Can walk very nearly as well and as fast as ever he could, but can no more run than a baby, his feet refusing to "go into the right shape." His legs do not give, but he occasionally staggers, though the merest touch of any support at once

Digitized by Google

steadies him; the staggering is no worse in the dark; the knee-jerks are now only slightly exaggerated; the left leg is under better control than the right; there is little fault, however, to find with either. Any delicate work makes his hands shake—e.g., picking up tacks or cutting leather; to write is hardest of all. This tremor is worse when he is watched, and sometimes is entirely absent. He has less control of the left hand than of the right. His speech is hesitating occasionally; no stuttering nor scanning. His voice is a little thick, and the words slightly slurred; these come to his mind readily enough, "but something in my mouth seems to stop me from speaking." There is distinct paresis of the left side of the mouth. Has noticed no difference in his sexual powers, and has lately become a father. Has had no difficulty with the bowels or bladder. Electrical reactions fairly normal. The following were the results with the constant current of a Stöhrer's battery:—



R. extensor indicis—C.C.C. with 10 cells; A.C.C. with 12 cells.
L. extensor indicis—C.C.C. with 18 cells; A.C.C. with 22 cells.
R. tibialis anticus—C.C.C. with 22 cells. A.C.C. with 26 cells.
L. tibialis anticus—C.C.C. with 18 cells; A.C.C. with 24 cells.

He has not been subjected to treatment of any kind since he left the hospital.

Remarks.—Recovery after a rectal temperature of 111° is, as far as I can learn, of extremely rare occurrence in rheumatic fever. The noteworthy points about the pyrexia in this case are, I think: 1. Its steady rise under fairly full doses of salicylate of sodium (140 grains in fourteen hours). 2. Its apparently much more rapid rise on the administration of this drug being stopped. 3. Kairin (144 grains in forty-eight hours), given during a subsequent rise, is noted both by Dr. Russell and myself as having had no appreciable antipyretic action. 4. Large doses of the sulphate of quinine (100 grains in thirty-six hours) acted splendidly as a stimulant, the effect of the first dose of twenty grains being especially marked, whilst none of the ill effects of cinchonism were noted. I believe it was also a very active antipyretic. 5. The employment of cold water, as instanced by the pack on Oct. 4th as well as by the bath, was by far the most potent agent in reducing the temperature. 6. Was the running up of the temperature on Oct. 4th in any way due to the brandy? Did it affect injuriously the thermic centre by dilating its arterioles? It was the first alcohol he had taken since admission. 7. The pyrexia had great persistency. The two attacks of semi-consciousness previous to admission were no doubt attended with high temperature, and it was not until after ten days of antipyretic treatment that the normal was reattained. 8. The pyrexia did not return during his stay in hospital—three months. Morning and evening temperatures were taken.

If I may venture to suggest anything as to the method of employing cold water as an antipyretic, I would say its action is often not sustained for a long enough period. In the present case I was strongly advised to remove the patient from the bath twenty minutes before I did so; I believe I should have acted more wisely if I had detained him in it thirty minutes longer, raising the temperature of the water gradually to blood heat. But the nervous affections form by far the most interesting feature of the case. They were too permanent to be explained as mere functional derangements due to the action of the hyperpyrexia. They must have been the result of some organic lesion, probably an inflammation set up by the rheumatic poison. We know this can widely distribute its influence and attack various regions of the body—e.g., lungs, heart, muscles, joints, skin, &c. It seems remarkable, then, not that the nervous tissue should sometimes be affected, but that this affection should occur so rarely. Briefly these nervous affections may be summarised as follows:—1. Paresis of some of the muscles supplied by the twelfth, ninth, and seventh cranial nerves on both sides of the body. 2. Some loss of the motor and coördinating power in all the limbs, but chiefly in the left arm and right leg (cross paralysis). 3. An alteration of the temperature sense. 4. A lessening of the liability to catch cold. A diffused inflammation of moderate intensity occupying the substance of the medulla and lower half of the pons would account for these conditions, and seems to me to offer the most probable explanation of their cause. The changes in the temperature sense, while both that of locality and common sensation remain practically unchanged, are of extreme interest. I cannot help accepting the patient's statements with regard to them as facts, for he is a man of great intelligence and volunteered them to me unasked. I can offer no simple explanation of their somewhat contradictory nature, and have no space in which to discuss vague probabilities. My own inclination is to suppose a thermic centre (as advocated by Maclagan) with special centripetal nerves, that this centre is functionally and anatomically closely related to the vaso-motor centre, and that it has been morbidly altered by the same inflammation which I believed produced the other nervous affections. Disturbance of a thermic centre will also account for the hyperpyrexia. In favour of this view that hyperpyrexia is due to an organic lesion, it must be remembered that this symptom, when it occurs, is by no means a transitory one. In the present case the tendency existed for ten days, notwithstanding energetic antipyretic measures, and in the case reported by Mr. Teale[1] a temperature never below 108° lasted for seven weeks. In fact, in cases which recover it has nearly always been a symptom of considerable duration. It is true that in the majority of the reported cases it has only existed for one or two days, but this is because the death of the patient gave it no chance of continuing longer. Again, in all the cases of which I can find complete records, other definite signs of bulbar mischief exist. This lends additional likelihood to the suggestion that hyperpyrexia itself may be due to lesion of the medulla.

Specimens of the Patient's Handwriting at dates stated.

Not much weight can be attached to the absence of any observable nervous lesion post mortem in Dr. Ringer's cases;[2] in fact, such could hardly be expected, since in the longest instance hyperpyrexia only lasted some forty-eight hours. Besides, no one at present could receive the most carefully proved post-mortem negation as an absolute one. The post-mortem examination on Dr. Bristowe's piquante and redoubtable "Marion"[3] (who had ophthalmoplegia externa, right hemiplegia and anæsthesia, epileptiform attacks, &c.) made all those who had watched the aberrant manifestations of her life ask with increasing scepticism the question of jesting Pilate, for the most painstaking investigations of Dr. Hadden enabled him to discover nothing worthy of the very least of them all.

My lovingly esteemed master, Dr. Russell, was about to publish this case himself when death took him from us; many of the most valuable notes are in his handwriting, and for these I am indebted to his son, my friend, Mr. James Russell.

THE ACCIDENT TO MR. WILLIAM ADAMS.—We are glad to learn that the accident which happened to Mr. William Adams at the Colonial and Indian Exhibition last week is of a less serious nature than was thought probable. The wound in the hand is healing rapidly, and is not likely to result in any permanent injury.

ON A CASE OF LITTRE'S HERNIA.

BY JOHN H. MORGAN, F.R.C.S.ENG.,
ASSISTANT-SURGEON TO CHARING-CROSS HOSPITAL.

IN a paper on a New Form of Hernia published in the "Mémoires de l'Académie Royale des Sciences" in 1700, M. Littre described a condition of incarceration of intestine which had not been previously recorded, except by Hildanus in 1598. Littre's attention was first attracted by the case of a stout man, aged forty-eight, who died suddenly with a hernia in the left groin. He found a part towards the end of the ileum arrested in the sac of a hernia, which could not be easily withdrawn, although not adherent. The whole circumference of the intestine did not form this hernia, but only the portion opposite to that which is immediately attached to the mesentery. Thus the continuity of the canal was not interrupted. There arose also a lengthening of that part of the intestine engaged in the ring, so as to cause the formation of a sort of appendix of conical shape with a large base below, and communicating at its upper part with the cavity of the ileum. Its thin walls and fine vessels showed it to differ in structure from a naturally formed appendix. In a second observation, he found in a man who died of fever, aged thirty-four, a hernia, not strangulated, formed by an appendix of the ileum, which alone was engaged in the ring, whilst the rest of the circumference of the body of the intestine remained free. A third instance is related of a man with a tumour in the left groin, of which he died in five days. This it was difficult to recognise as a hernia, since the man had no distension and was hardly inclined to vomit. Owing to decomposition, the parts did not reveal the exact state, but probably the same condition existed as in the other two cases. Among other causes for strangulation of these herniated appendices are the thickness and weight of the material which accumulates in them, which are unable to regain the continuity of the gut through the narrow opening, and are unaided by the intrinsic muscles of the appendix, which have lost power from distension, or by the extrinsic forces of the abdominal walls, which can no longer act upon them. The condition, then, which Littre described, but which has since acquired a rather loose signification, is one in which a section of the gut is forced into a hernial opening and, becoming distended and enlarged, forms a distinct appendage. The condition has been frequently described, and is not one of very uncommon occurrence. The strangulation of this part is very frequently followed by gangrene, owing perhaps to the delay which may ensue from the difficulty of recognising the condition and the anomalous nature of some of the symptoms. That gangrene is not necessarily the cause of a fatal issue, and that this may ensue from other causes, are shown by the following case, which is one of considerable interest and instruction.

I was asked by Mr. Humphry, of St. George's Dispensary, to see with him an elderly woman, who stated that her age was sixty-four, although she looked even more advanced in years. She stated that she had been a domestic servant, and had generally enjoyed good health. For some two or three years she had been losing flesh, during which time she had been of constipated habit, for which she had resorted to aperient medicines. At various times she had passed blood per rectum when at stool, but never to any great amount. There was no family history of phthisis or of malignant disease. Seven days prior to my seeing her, finding herself constipated, she took her usual remedy, which was followed by an action of the bowels, and this was again succeeded by a more obstinate constipation. She was treated at first with purgatives, and subsequently by enemata. Nothing, however, had passed with the exception of some blood in streaks and mucus, which was accompanied with tenesmus. She had vomited a little dark material, which was not stercoraceous. There was some pain, constant but by no means urgent, referred to the umbilicus. There was no hiccough. We found the patient lying on a rough bed in an underground ill-lighted room, and in a very feeble condition. Her emaciation was extreme, so that, in the words of the registrar's report, the body appeared free of all fat. She was sent by my advice to Charing-cross Hospital, where she was seen by myself and colleagues the same day. Her condition was one of extreme feebleness and exhaustion, but the more thorough examination which was available under these circumstances revealed the fact that there was no local tenderness at any part. The abdomen was moderately distended and tympanitic; no peristaltic action of the intestines could be observed. Nothing could be detected at any of the usual sites of hernia, but a large flaccid protrusion of the vagina evidently containing intestine, and at the apex of which could be seen the minute os of a very atrophied uterus, passed from out beyond the labia. This was reducible with the simplest pressure, and it seemed evident that nothing in the condition of its contents was giving rise to the symptoms. The walls of this protrusion as well as the labia were covered with dry crusts of secretion, which had in some places come away, exposing small weeping excoriations. No tumour could be detected in the abdomen, and palpation gave rise to no pain, nor was there any indication as to the seat of mischief. Her eyes glistened brightly, but there was a marked facies Hippocratica. Such was the state of collapse that no operative measures could be undertaken. She was ordered a pill containing opium and belladonna, and if she improved an injection was ordered to be administered. Her temperature was 97° and pulse 92. No flatus was passed per rectum. On the following morning the temperature was 98° and the pulse 100. She was somewhat less feeble and complained of no pain. She had twice vomited, and though the material thrown up was only suspiciously stercoraceous on the first occasion, it was undoubtedly so on the second. I again carefully examined the abdomen, but with a negative result. I observed, however, a very slightly enlarged gland about the middle of Poupart's ligament, which had not been noticed the previous day. This might be due to an excoriation of the corresponding labium, but in view of the symptoms I carefully examined the femoral region for any sign of hernia, which, owing to her great emaciation, might be expected to be manifest, however small the protrusion. No sign either of tenderness or of difference from the corresponding region could be detected. Nevertheless, I felt strongly tempted to cut down and explore the femoral region; but after consultation with my colleagues, and after giving due weight to all the previous history and the present symptoms, I determined to cut down upon the colon in the right lumbar region, and, should this be found empty, to perform laparotomy and seek the cause of obstruction. This was accordingly done; the colon was immediately found, but its collapsed condition showed plainly that the obstruction was situated above the commencement of the larger bowel. No time was lost in closing the wound after the bowel had been examined, and no blood was lost; but it was evident that the patient would not bear any further operation, and I was obliged to relinquish the hope of relieving her. She was sent back to bed, and died the following morning.

Necropsy.—Lungs œdematous at bases and emphysematous throughout. The left ventricle of the heart was hypertrophied, the muscular tissue soft and flabby. Abdomen: The upper part of the small intestine down to within ten inches of the cæcum was distended with flatus. At this portion a very small portion of the circumference of the gut had passed into the femoral canal on the left side, where it was impacted and fixed. There were no adhesions; the herniated portion was very slightly discoloured, and showed no sign of becoming gangrenous. The lumen of the gut was continuous, but the part beyond was collapsed and smaller than that above. There was also a number of coils of small intestine in a pouch behind the uterus, which was prolapsed beyond the labia. There was no peritonitis. The uterus was exceedingly atrophied, and the os would hardly admit the point of a hairpin. There was advanced rheumatoid arthritis in both hip-joints.

The diagnostic symptoms which Littre gives as distinguishing this form of hernia are—(1) that the patient regularly discharges his motions, since there is no interruption to the continuity of the canal; (2) that there is seldom hiccough, and vomiting is less frequent than in ordinary herniæ, and never stercoraceous; (3) that the abdomen is neither large nor distended; (4) that the tumour increases more slowly and never attains a large size; and (5) that the inflammation, pain, fever, &c., take longer to show themselves, and are less violent. With regard to the first of these symptoms, it could be gathered from the woman's account that, as far as previous history went, there was good reason to suspect malignant disease. To this explanation her age,

Digitized by Google

the extreme emaciation, the habitual constipation becoming more and more pronounced, and the passage of blood and mucus all seemed to point. Hiccough was never present, and the vomiting did not occur till late in the period of illness, and was only stercoraceous on the day preceding death. At no time was the abdomen distended or painful, and, though not stated by the patient or those around her, it is to be presumed that flatus made its escape through the continuity of the gut. There was no tumour to be found at any period; and the only indication of anything like inflammation was the slight enlargement of an inguinal gland on the second day of her being in the hospital, which might readily be attributed to the excoriation of the labium. Strong as were the probabilities of hernia, this was the single indication as to its possible situation.

The intense collapse of the patient was a restricting influence as regarded operations, but under the circumstances there were three proceedings which might be undertaken: (1) herniotomy in the left femoral region; (2) laparotomy and exploration of the abdomen and its contents; and (3) colotomy, on the presumption that a malignant stricture existed in some portion of the large intestine. The first of these measures I rejected, though with some reluctance, since the indications, not so much of hernia as of its site, if existent, rested upon very slight foundation. Had it been adopted, the condition of the parts makes it probable that the herniated segment of gut, even if detected, could hardly have been satisfactorily dealt with. The second proceeding would, I think, have been the proper course to adopt in a patient less exhausted, or in a younger person suffering from similar symptoms. By following up the collapsed intestine, and thus ascertaining the cause of obstruction, a very slight force would have sufficed to draw the small herniated portion of gut out of the femoral canal. There must, however, even with the greatest care, be a certain amount of shock attending any such operation; and there is little reason to suppose that the patient could have borne such a proceeding, as shown by the result of the milder measures which were adopted. I was driven, therefore, to resort to the proceeding which had at least the merit that it offered less shock to the patient, and if successful would afford a chance of present relief and possibly of prolonged comfort.

NOTES OF CASES OF

PUERPERAL CONVULSIONS TREATED WITH PILOCARPINE.

BY JAMES MURPHY, B.A., M.D., &c.,
LECTURER AT THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, AND SURGEON TO THE SUNDERLAND INFIRMARY.

IN connexion with the case of successful treatment of puerperal eclampsia by pilocarpine recorded in THE LANCET of April 3rd by Dr. Horrocks, the notes of the following cases may prove of interest.

CASE 1.—On Nov. 27th, 1885, Dr. Prowde asked me to see Mrs. C——, aged thirty, at the Sunderland Workhouse. She was admitted on Aug. 20th, and was eight months pregnant with her first child. A month before I saw her she showed signs of œdema, and this continued till Nov. 27th, when she was seized with violent convulsions, which recurred every twenty minutes, and then she at once lost all consciousness and could not be roused in the intervals between the fits. Her breathing was markedly stertorous; her pulse 120, hard and wiry; her face, trunk, and extremities very much swollen; and the small quantity of urine removed from the bladder became almost solid on the addition of heat and nitric acid. The cervix was hard and had not been taken up; the os would admit a No. 12 catheter; the vagina was dry; and, in fact, there was no sign of labour. A third of a grain of pilocarpine was at once injected beneath the skin of her arm; within two minutes saliva commenced to pour out of her mouth, necessitating the use of a tin vessel to catch it in; and within five minutes she was in a profuse perspiration all over her body, the drops standing out on her forehead and chest like large beads. She had a slight convulsion shortly afterwards, which was the last she had, and obviously the question at once presented itself, Should labour be induced or an expectant treatment followed? After anxious consideration, Dr. Prowde and I decided that it would be hopeless to permit pregnancy to continue in a completely water-logged woman, quite comatose, who had already had some twenty convulsions, and with her breathing and pulse as mentioned. The cervix was accordingly gently dilated with the finger, a Barnes's bag introduced, then another, and so on till the os was fully dilated, which occupied a little over two hours, when Tarnier's new forceps was applied, and a living male child delivered, chloroform having been freely administered the whole time to prevent muscular movements and to assist the pilocarpine to lessen arterial tension. She continued insensible and almost maniacal for two days, on each of which she had a third of a grain of pilocarpine, which roused her and made her more sensible for some hours, and she then rapidly improved, the urine gradually becoming freer from albumen, till at the end of a fortnight it was normal, and at the end of a month, thanks to Dr. Prowde's skill and attention, she and her child left the workhouse, both quite well. She had suffered for many years from right facial paralysis and slight deafness on the same side, which were in no way affected by the attack or the treatment.

CASE 2.—On March 6th, 1886, Dr. Coatsworth Watson sent me an urgent message to come to assist him with a lady, aged twenty-eight, who had gone a fortnight beyond her calculated time with her first child. She had spent an excellent pregnancy, and on this day had been out for a walk, but complained very much of headache, and latterly had some swelling of the legs. An hour before I saw her she was suddenly seized with a convulsion, and lost all consciousness. On Dr. Watson's arrival he at once administered chloroform, without producing any effect on the convulsions, as (though I was summoned by telephone and arrived very shortly after him) she had had four fits during its administration, and as I entered the room was in one of the most violent convulsions I have ever witnessed, and appeared to be on the point of death. A third of a grain of pilocarpine was quickly injected, which acted rapidly, and she had no more convulsions during her labour, but it was deemed safer to continue the chloroform; her pulse was almost imperceptible, ranging from 140 to 150, and her breathing stertorous. On examination, the head was found well down in the pelvis, and the os thin and of the size of a shilling; an ounce of urine was drawn off highly charged with albumen. Having rapidly but carefully discussed all the circumstances of the case, Dr. Watson and I decided to at once rupture the membranes, and to introduce the largest sized Barnes's bag, which, as the pains were very strong, was expelled in about twenty minutes, when Tarnier's new forceps were applied and a dead male child delivered. Two hours later a second third of a grain of pilocarpine was administered as a prophylactic, and all went on well for twenty hours, when she had a slight convulsion, necessitating the administration of a third dose of pilocarpine, after which Dr. Watson placed her on a mixture of jaborandi, which in a few days was changed for tincture of the perchloride of iron and spirit of nitrous ether, and under his skilful and judicious care she made a speedy and excellent recovery, the albumen disappearing on the fifth day.

CASE 3.—On April 14th, 1886, Dr. H. Shapter Robinson kindly asked me to see a primipara, aged twenty-one, whom he had attended ten hours previously in her first confinement, all going on well. Shortly after he left the house convulsions set in, and occurred every half-hour up to the time of our visit, when we found the patient in a dazed condition, with widely dilated pupils; but she could be roused to answer questions fairly well. A third of a grain of pilocarpine was at once injected into her arm, and in a few minutes the characteristic salivation and diaphoresis occurred; and with the exception of one slight convulsion afterwards all went on well under the able and efficient treatment of Dr. Robinson, who, on the occurrence of the last-mentioned convulsion, injected a second dose of pilocarpine. Mother and child continue in excellent health.

This case makes the sixth that I have treated with pilocarpine, the first five being very severe cases; and I am thankful to say all the mothers made excellent recoveries, and four of the children were saved and are now alive.

My first case occurred in my own practice on March 30th, 1883: a multipara aged thirty-nine, in her tenth pregnancy. She had nine convulsions before being seen, and was comatose and œdematous. The urine contained a large quantity of albumen. One-third of a grain of

Digitized by Google

pilocarpine was administered every six hours. Labour came on twenty-four hours after the first visit; child dead. The mother became conscious next day, and rapidly recovered. My next case occurred on June 6th, 1883, in a patient of Mr. Morgan's, a multipara, aged twenty-eight, seven months pregnant. She had thirty-three convulsions. The urine contained a large quantity of albumen. Chloroform and other remedies failed. One convulsion only occurred after the administration of pilocarpine. Pregnancy went on to normal length; living child. These two cases are recorded fully in the *American Journal of Obstetrics* of December, 1883, and an analysis of the urine in the second case is given, showing how the urea was diminished.

The third case occurred on March 27th, 1884, and is recorded by Dr. Ridley Dale in the *Medical Press and Circular* of April, 1884. The urine was very much reduced in quantity, but at the onset there was no albumen, which, however, appeared in a few hours. Pilocarpine having been administered, the convulsions ceased; but they returned next day, when the drug was again administered, with cessation of the convulsions. Both the mother and child did well.

These six are the only cases of eclampsia I have seen during the past three years, and in their treatment pilocarpine has acted so satisfactorily as to leave little to be desired.

THE CASE OF EDWIN BARTLETT.

MERCURIALISM; DEATH FROM LIQUID CHLOROFORM; NECROPSY.

By ALFRED LEACH.

(*Concluded from p. 970.*)

THE remaining peculiarities of the patient are grouped in the following account of my twenty-two days' observation. The general condition on Dec. 10th is given at the beginning of this article. In my notes of Dec. 12th to the 16th the following passage occurs: His physical symptoms rapidly improved; but his spirits did not. He said his gums pained him, and that he could not obtain any sleep whatever. Bromide, opium, and injections of morphia (seven minims thrice a day) were almost without effect; bromide of ammonium in one-scruple doses or more he repeatedly declared irritated him and made him restless. The bowels were acting regularly, and he was taking food. The dulness to percussion over the region of the abdomen suddenly shifted from the left iliac to the right lumbar region, and a swelling as large as a hand accompanied it, but disappeared in a day or two (phantom tumour?). On the 17th *et seq.* he suffered from "wind," and a mixture of carb. veg. c. confec. rosae found favour with him. When advised to go for a drive he declared it would kill him; he liked "to lie still and feel happy." His spirits were better, and he engaged in conversation. He began to talk about his return to business, his movements and plans for the future, but always a remote future; for the present he could not be persuaded to leave his bed. He had his stumps drawn with a view to having a set of false teeth made later on. He thought about his health unduly, exaggerated his alleged weakness, but did not expatiate on any special trouble or fix his mind on any individual organ or symptom. He could not be said to be anxious about his condition; he was contented to think it bad. He blandly inquired: "Can one be as bad as I and yet survive"? He adopted the inference with prophetic apathy. He emerged occasionally from his usual reserve, but still shyly, to bestow praise on absent persons, or, more timidly, on persons present. He expressed to his wife unbounded confidence in his doctor, and occasionally said he "knew the doctor would cure him." He was depressed by trifles, but never angered by anything. He was passive under treatment, and did what he was told, provided it involved no great effort. He would smile, but seldom laugh. When alone with his wife he was said to weep bitterly for more than an hour at a time, and said he did so "because he felt so happy." He said the world was very good to him. He gave one the impression of suffering from partial paralysis of the will and emotional ataxy. His wife remarked in his presence, "You would not think, seeing him now, that he rules a staff of *employés* kindly and considerately, but with unequalled firmness." By all accounts this was perfectly true. He was a sound man of business, "talented" one might say, very straightforward, and strictly honourable. Drawn into conversation on his hobby, he would brighten up amazingly, and afford interesting information on the laws of demand and supply, of imports and exports, down to the minutiæ of the grocery business. With him trade was a profession. On Dec. 18th he acknowledged that he was getting better, but he and his wife requested me to bring in a physician to witness the fact, giving as reasons that family disturbances and dislikes existed. The only reproachful word I ever heard him utter was on this occasion, when describing the part played by certain of his relatives. Asking for the consultation, he rose in his bed excitedly, saying, "I do this for the protection of my wife." On the 19th Dr. John Gardner Dudley visited him with me, and has kindly permitted me to transcribe and abridge portions of the notes he made on the occasion. "*Condition:* I found the patient lying in bed in an easy position and apparently free from discomfort. He had a depressed mental appearance, and looked at me through his eyelashes, his eyelids being half closed. He said he was quite free from pain, excepting that his gums were very uncomfortable from having had teeth extracted. He said he kept his bed because he preferred it to sitting up, and that he had been much overworked, mentally and bodily, and required rest and sleep. He also said he had not slept well for a considerable time, and scarcely at all the last few nights. I found his gums much inflamed and spongy; the edges were ragged. His tongue was large and flabby, and indented by the few teeth he had left, and was very slightly coated. His bowels were acting regularly; his urine was normal; his temperature normal; his pulse 80, and of moderate volume; chest and abdomen normal. I told him he was a sound man, and that he ought to sit up and go out daily for a walk or drive. We prescribed fifteen grains of hydrate of chloral, fifteen grains of bromide of ammonium, and twenty minims of solution of hydrochlorate of morphia, to be taken at bedtime, and repeated in four hours if necessary. Also a tonic mixture containing acid, nux vomica, and taraxacum, to be taken at 11 A.M. and 4 P.M. daily."

Dr. Dudley's notes also mention, among facts that struck him, the wife's solicitude and attention—a remark that has my fullest concurrence; a kinder, more tender, more patient, or more self-sacrificing nurse could not have been wished for. Beyond making a mental note of this fact when I began my attendance, I very naturally took little further notice of the Bartletts' bearing towards each other; but I distinctly remember at first receiving an impression that there was something unusual, something unfamiliar to one's everyday experience, in their behaviour one to the other—a freshness in their affections, if I may so express it, together with a reserve in their approaches. I jumped at the very inappropriate conclusion that they were newly-married people, and thought no more about it until I was informed of the non-existence of sexual relations between the parties. I was unprepared when in the witness-box to detail the several cogent reasons I have for accepting in the main this statement, and I am not at liberty to give them here; their suppression was and is of no moment, and many medical men have already, by drawing independent conclusions, accepted the statement as possibly true. I have grounds, too, for believing that the patient was not devoid of moderate sexual appetite, though its gratification was not permitted to conflict with his marriage compact. Specially examined after death, his genital organs were found normal. I protest strongly against the supposition, unwarranted by any evidence whatsoever, that the deceased was a victim to a degrading secret vice.

On Dec. 21st, when his teeth were extracted, a peculiar and suggestive circumstance occurred, which tends to throw some light on the man's character. He had a firm belief that he could not be brought under the influence of "laughing gas," because in former years medical men and dentists had failed to produce anæsthesia in him by its aid, and had told him he "could never be brought under." I resolved to avail myself of the peculiarly impressionable nature of the patient and his unreasoning belief in my powers; so, after preparing his mind by a discourse upon the voluntary abolition of painful sensations and a mystical manipulation of a camel's hair brush saturated with cocaine, I informed him that he could no longer experience any sense of pain in his lower jaw. I placed him in position, signalled to the dental

Digitized by Google

surgeon to commence operations, and treated the patient to a clinic somewhat in this style: "Now, what you feel is merely a sense of chill from contact with a metal and absolutely painless. Lie still and keep the mouth open. Now you feel the teeth painlessly dropping out from the insensible sockets, and it does not hurt you in the least. The sensation is almost pleasurable." The four lower incisors had flown out, and the patient had kept his eyes inquiringly fixed and never winced. He was puzzled to say whether he had suffered or not. Ordinarily he could not bear to have his gums or teeth touched by his own or other person's finger. I have never practised this pious fraud before, and am doubtful whether I shall ever meet with another case in which it will bear repetition. Ten days later, when his left lower canine required removal, I was lacking in faith enough to resort to it. I could not cajole him into a resolution to go out of doors, but he managed to get out of bed and totter about the room. His wife on several occasions told me before him, "He still talks about dying and not recovering." He would not explain his reasons. She also said that he slept a good deal better than he thought he did. He consented to go to Torquay, but postponed his departure *sine die*. He and his wife both protested against a diminution of professional visits, declaring that he "derived strength" from them and felt weak in the intervals. I was desirous of removing him from both his wife and myself, but he persisted that strangers would not understand his complaint. He would not have a nurse. His wife still sat up all night, or took short sleeps on the sofa or in the arm-chair by his bed, and, when remonstrated with, she declared in his presence that he would not compose himself or rest unless she sat by holding his foot, and when she was absent from her post he would leave his bed and wander. By day he showed no such inclination. He was now obtaining some sleep, had lost no flesh, his muscles were firm, and his countenance more cheerful. One morning he told me that, being unable to sleep and feeling exhausted, he had risen from his bed and stood for two hours with his arms outstretched over his sleeping wife, and "felt her vital energy entering his finger tips," after which he slept. His urine at this time was slightly acid, sp. gr. 1010, otherwise normal. On the 23rd he was much perturbed from having passed the lumbricoid worm. On the 26th he confided to us his belief that he was mesmerised, and that he and his wife were alike victims to the mesmeric influence of a friend whose acquaintance they made some months previously. The only explanation he would afford as to the symptoms was that he was doing such strange things—things contrary to wont, usage, and common sense—things he would not do unless he were under mesmeric influence. I have not the slightest doubt he meant the peculiarly Platonic arrangements he had made as to his wife's future. Was this about mesmerism a delusion? I think not; I regard it as a hysterical attempt to render some extenuating account to himself for the absurd folly of his own proceedings. I was able a day or two later to successfully argue him out of his mesmeric theory. I believe no argument reaches an insane delusion. On the 28th I took him by surprise and insisted upon his going a drive with me while I went my rounds. It was genuine alarm and misgiving he showed as, muffled up from head to foot, he was assisted downstairs by two people. On his return he ran upstairs quite lightly, and the next day went a drive with his wife. On the 30th I did not visit him. On the 31st he had a tooth out under gas. On his return home he ate a good supper, ordered an extra allowance of breakfast for the next morning, and soon after midnight died from swallowing chloroform. His wife fell asleep about midnight in her usual place, holding his foot, and on awaking was struck, but not alarmed, by the peculiarity of his breathing. She awoke again about 3 A.M. or later with a cramp in the arm holding his foot; and, seeing his face buried in the pillow, she proceeded to place him more comfortably, but found him apparently dead. She tried to revive him, applying brandy, &c. On arrival at 4.30 A.M., Jan. 1st, 1886, I found the corpse lying on its back, forearms and hands on the abdomen, legs semi-flexed and everted, the parts of the thorax lying uppermost quite cold, the hottest parts of the back being below 95° F; eyelids partly closed, pupils half dilated; tongue very white; no smell whatever in the mouth, and no froth; rigor mortis absent. Dead about three hours (?). There was no trace of any struggle, and no poison in the vicinity of the corpse (a very careful search for [illegible] was made). Cause of death unknown. I have subsequently discovered by experiments that liquid chloroform whitens the epithelium of a furred tongue, especially a "smoker's tongue," while its rubifacient effects are alone discernible in a glazed or clean tongue. In the corpse and in the living body the white appearance is lost in five or six hours.

The necropsy was performed on Jan. 2nd at 2.30 P.M., about thirty-eight hours after death, by Dr. T. H. Green (from whose notes I am kindly permitted to quote), assisted by Dr. H. M. Murray. Present: Dr. J. G. Dudley, Mr. W. W. Cheyne, F.R.C.S., and myself. Body well nourished; on the abdomen much cutaneous fat of deep-yellow colour. Rigor mortis present. Heart: On opening the pericardium nothing abnormal; heart, on removal, normal in size; muscular tissue a little flabby, probably from post-mortem causes; valves healthy; tiny patch of atheroma at root of aorta; the post-mortem staining of the lining membranes of the cavities and large vessels abnormally deep; blood in cavities dark and quite fluid. Lungs and pleuræ normal. Liver, spleen, kidneys, mouth, pharynx, trachea, and upper part of œsophagus normal. Œsophagus at its lower part abnormally vascular and irregularly denuded of its epithelium. Stomach: Nearly an ounce of contents, consisting of a brownish grumous liquid, varying in consistence; the more solid portions are paler in colour, and look something like thick mucus; smell strong, pungent, ethereal odour, resembling a combination of chloroform and garlic. At the cardiac end of the stomach the mucous membrane is of a dusky pink colour, which, to the naked eye, looks uniform, but under a lens there is a distinct punctiform and capillary hyperæmia; the surface is covered with an abnormal amount of thick tenacious mucus or lymph; at what appears the most dependent part there is a patch about the size of a five-shilling piece, where the mucous membrane presents a rough irregular appearance, as though it were partly destroyed; here the membrane is more easily removed by the finger-nail than elsewhere. In other parts of the cardiac end the mucous membrane is not easily removable. The pyloric end of the stomach is of a pale-greenish colour, covered with a tenacious mucus, but otherwise normal. Intestines: The contents present the same peculiar odour in a less marked degree and less pungent. Some small pieces of what appears to be mango chutney were found in the whole length of the intestines, and one or two pieces were observed in the stomach. The mucous membrane is normal. The large intestine contains much fæcal matter. Head: On removing the calvaria, the dura mater was found abnormally adherent. With exception of rather more post-mortem staining than usual, the surface of the brain presents nothing abnormal. A careful examination of the brain throughout failed to reveal anything abnormal.

On Jan. 6th I excised the lower jaw, the tongue, and surrounding parts (subcutaneously), and made a section of the incisor region. The edges of the vacant sockets were blackened to the depth of one-sixth of an inch; the rest was healthy. The alveoli contained decomposing matter. Dr. T. Stevenson, the Government analyst, found 11½ grs. of pure chloroform and a trace of alcohol in the contents of the stomach. A considerable evaporation had taken place before these reached him. He found unimportant minute traces of lead and copper in the substance of the lower jaw. The stomach, jaw, and tongue were the only parts sent for analysis.

The general opinion seemed to be that the patient had met with his death by about an ounce, or probably less, of chloroform finding its way into the stomach. The unsolved problem is, Did he take it as a soporific, an anodyne, or as an instrument of suicide? Did he, acting upon impulse, take it with no well-defined purpose whatever, or did he (and I have a leaning to this view) take it in sheer mischief with the intention of alarming by his symptoms the wife who an hour or two previously had talked about using it in an emergency? The problem in diagnosis is: What was he suffering from: melancholia, hypochrondriasis, or hysteria—one or more of them? The loss of flesh, the aversion to food, the urine loaded with urates, the inactive skin and liver, the obstinately inactive bowels, the overwhelming and persistent gloom of melancholia, were absent in this patient, who "liked to lie still and feel happy." On the other hand, we miss the eagerness of the patient to describe his ills, the anxiety to interpret special symptoms, the desire for recovery, the greed for medical literature, and the inevitable bundle of former prescriptions that stamp the hypochondriac. But what symptom of hysteria is absent?

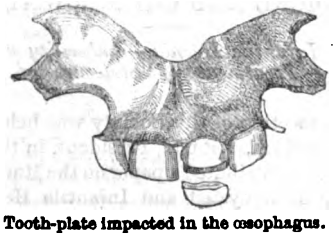
Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.



ST. THOMAS'S HOSPITAL.

TOOTH-PLATE IMPACTED IN THE ŒSOPHAGUS; SUCCESSFUL REMOVAL BY ŒSOPHAGOTOMY; REMARKS.

(Under the care of Sir WILLIAM MAC CORMAC.)

IT is now generally conceded that the treatment of foreign bodies impacted in the œsophagus, where unsuccessful attempts have been made by the use of forceps &c. to extract them, should be by an operation—œsophagotomy,—as in the following case. Here, as will be seen from the diagram illustrating the case, the plate with very irregular and pointed projections had become fixed, and resisted all attempts to remove it. The operation has been a very successful one when undertaken before the advent of inflammation or suppuration about the œsophagus; the chief danger appears to be in delay. The point in the treatment to which Sir William draws attention in his remarks (the closure of the œsophageal wound by suture) is one which will probably be generally adopted in similar cases, as it presents considerable advantages. The notes of the case have been taken by Mr. Cameron Kidd, house-surgeon.

The subject of this accident was a woman, aged thirty-one, of healthy appearance, but subject to epileptic fits since childhood. During one of these fits, which took place on Sunday morning, March 14th, the patient swallowed a set of artificial teeth, consisting of a silver plate to which five teeth (four incisors and one premolar) had originally been attached, but one of these (the premolar) had been

Tooth-plate impacted in the œsophagus.

broken off some time before the accident occurred. (See engraving.) When the patient regained consciousness she had some difficulty in breathing and swallowing, and then discovered what had happened. She immediately consulted a doctor, who gave her an emetic, which caused her to vomit without moving the plate, and an attempt to extract them with forceps was made without success. She was then advised to apply at St. Thomas's.

On her arrival at the hospital two hours after the fit, there was no difficulty in breathing, but there was considerable pain on drinking. An œsophageal bougie, carefully passed to ascertain the position of the foreign body, became arrested at a point six inches and a half from the edge of the teeth. The patient said she could feel the tooth-plate from the pain it caused, which she referred to a spot an inch below the cricoid cartilage. Mr. Battle made repeated and prolonged efforts to extract the foreign body by means of œsophageal forceps of various kinds. The plate was repeatedly grasped by the forceps, and as much force used as was thought justifiable, but all attempts to disengage it failed. Some slight hæmorrhage followed. During one attempt half a tooth was broken off and was extracted. The plate was evidently flattened against the posterior wall, as the forceps went past it, and it could only be grasped when they were withdrawn a short distance and passed again with the blades open. The patient, who was admitted on March 14th, was seen by Sir William Mac Cormac at 7 P.M., but as there was no dyspnœa or other urgent symptom, it was decided to postpone any further action until the following day.

March 15th.—The respiration is quite easy, but the patient cannot swallow anything, even a small quantity of liquid, and she expectorates the saliva. She complains of severe pain just below the cricoid cartilage, and at the back of her neck. There is some cough.

Operation.—As every possible effort had been made to extract the body by the mouth without success, further attempts in this direction seemed unadvisable. The plate was of very irregular form, with sharp angular projections at each side. It was evidently very firmly lodged in the tube, and was not likely to be extracted without danger of tearing the œsophagus, entailing very serious risk. Sir William therefore decided to perform œsophagotomy, the position of the foreign body being distinctly made out by the bougie and forceps, although nothing could be felt in the neck externally. At 2 P.M., the patient being under the influence of chloroform, the œsophageal forceps was passed and the foreign body again plainly felt at the same point as before. An incision about four inches long was therefore made along the anterior border of the left sterno-mastoid muscle, extending downwards to within half an inch of the sternal notch. The superficial tissues were divided until the edge of the sterno-mastoid muscle was reached, and the edges of the wound retracted. The anterior jugular vein, which was somewhat larger than usual, gave some trouble at this point, but was finally drawn inwards with the thyroid body. Several veins required division after the application of a double ligature. The carotid sheath was exposed, the omo-hyoid muscle cut through, and the artery and vein drawn outwards by the finger of an assistant. After dividing about half of the sterno-hyoid muscle and drawing the thyroid body well over towards the middle line, the œsophagus was exposed, but even then the foreign body could not be felt through its walls. It was feared it might have passed into the stomach. The forceps were again passed through the mouth, but even with them the foreign body was not distinctly felt. As, however, the probabilities were strongly in favour of it not having shifted from the position it occupied before the operation, a longitudinal incision about three-quarters of an inch long was made upon the end of the forceps, and when the lips of the incision were held apart the plate was at once seen closely impacted against the posterior wall of the œsophagus. It was readily seized with a pair of forceps and extracted without difficulty. It was now decided to close the œsophageal wound. An ivory-balled probang was passed to cause the tube to project somewhat, and the edges of the incision were united with three catgut sutures. The external wound was disinfected with a 1 in 1000 perchloride of mercury solution. Two drainage-tubes were inserted, and the margins of the skin united with silk sutures. There was very little bleeding throughout the operation. The wound was dressed with iodoform, salicylic wool, and gauze bandages. The patient was ordered to be fed by the rectum, and not to have anything by the mouth.

March 16th.—On the wound being dressed this morning, it looked well and there was no puffiness. Patient had a nutrient enema at 12 A.M., and a similar one has been ordered every four hours. She has taken nothing by the mouth, and expectorates her saliva. Slept well; no pain. The temperature rose after the operation to 101°, and is now (9 A.M.) 100·4°; at 9 P.M. it was 98·4°.

18th.—The stitches were taken out and the drainage-tube removed. The wound was looking very well. The patient could now swallow her saliva and she was allowed a little milk, which she swallowed easily and without any pain. Nutrient enemata discontinued. Temperature A.M. 99·4°; P.M. 100°. There has been no regurgitation through the wound.

20th.—Last evening some milk came through the wound after drinking. The patient did not mention the fact till this morning, as she was afraid her supply of milk would be stopped. She is a restless, irritable woman, and dislikes the feeling of thirst. On taking off the dressings and giving the patient milk to drink, some came out of the lower end of the wound, which was perfectly free from inflammation and had healed, except at the spot above and below where the drainage-tubes had been placed. The nutrient enemata were ordered as before and the supply by the mouth stopped. Antiseptic dressings left off. Temperature normal.

22nd.—Wound again dressed; it was looking quite well. On drinking hastily, a little milk came out from the lower

Digitized by Google

end of the wound; a small drainage-tube was inserted there. The patient was still allowed to drink milk. The nutrient enemata were discontinued. Temperature, morning, 99°; evening, 99°. General condition excellent.

25th.—The wound is now soundly healed, with the exception of a small place at the lower extremity. No milk has passed through it for the past twelve hours, not even when the patient swallows quickly. Drainage-tube removed.

27th.—Wound completely healed. The patient had an epileptic fit at 4 o'clock this morning.

30th.—The patient was up on the 28th, and went home to-day. There is a linear cicatrix in the neck, scarcely noticeable. She can swallow as well as before, and without pain or inconvenience, even when taking solid food.

The patient was seen about a month later, and was in excellent health. She had been supplied with a new and securely fitting plate.

Remarks by Sir WILLIAM MAC CORMAC.—This patient was only sixteen days in hospital, having made a rapid recovery. The point of chief interest is the closure of the œsophageal incision directly after the removal of the plate. The introduction of the sutures was a little troublesome owing to the depth of the wound, and I consider the partial failure was due to imperfect closure of the incision, from an insufficient number having been passed. Had four or five sutures been introduced in place of three, this accident might probably have been avoided. The milk, however, only found its way into the wound on the sixth day, when the chance of extravasation into the cellular tissues of the neck would be past, and it soon ceased to escape. This practice appears preferable to introducing a tube into the stomach from the neck or mouth and allowing the wound to heal by granulation—at all events in cases such as this one, where there were no inflammatory changes in the parts, and the margins of the œsophageal wound were clean cut, and not bruised.

EUROPEAN GENERAL HOSPITAL, ADEN.

A CASE OF MULTIPLE ABSCESS OF THE LIVER; DEATH; NECROPSY; REMARKS.

(Under the care of Surgeon-Major COLSON.)

THE notes of the following case are by Assistant Apothecary Gardiner.

The patient, J. B——, a seaman, was admitted on March 2nd, complaining of severe pains in the right side. He stated that he was quite well before leaving Bombay (about Feb. 22nd), and was taken ill two days after sailing. He was quite emaciated and exhausted, skin and conjunctivæ yellow, tongue rough and dry. The temperature on admission was 102·8°. There was a good deal of bulging over the hepatic region, with pain and tenderness on pressure. On careful examination the liver was found very much enlarged, with a sense of fluctuation below the ribs. An abscess was diagnosed pointing anteriorly about half an inch below the ribs.

March 3rd.—The patient was placed under chloroform, and an exploring-needle introduced, pus being found. A puncture was made with a trocar, and about eight ounces of pus removed through the cannula. The cannula was retained in the abscess as a means of drainage. Antiseptic dressing was then applied. He was ordered milk, mutton broth, and stimulants.—Evening: Temperature 102·8°. Felt much easier. One drachm of solution of hydrochlorate of morphia to be given at bedtime.

4th.—Temperature 99·4°. Bowels moved twice yesterday. Says he feel comfortable and slept fairly last night. Three grains of quinine given twice. To continue stimulants, &c. Evening: Temperature 101°. Cannula removed and drainage-tube substituted. Morphia draught to be repeated.

5th.—Temperature 99·6°. He slept well last night and feels less pain in the side. Bowels moved three times; light-coloured and semi-solid. Respiration before and since operation has been very slow, numbering between 8 and 12 per minute. Five grains of quinine were given twice during the day.—Evening: Temperature 101·4°. The morphia draught repeated.

6th.—Temperature 97·8°. The bowels were not moved during the night. Slept [illegible] the whole night, and is in[illegible] 68; respiration 14. [illegible] 102; respiration 30. Appears [illegible] during the day, and is [illegible] grains of quinine to be given at [illegible] bedtime. Had passed urine [illegible]

7th.—Bowels moved twice last night, the second motion containing blood and pus. Temperature 99·6°; pulse 104; respiration 22. Five grains of quinine given twice.—Evening: Had three motions during the day, each one containing pus. Temperature 103°; pulse 110; respiration 26. Is very low. To continue support by stimulants, &c.

8th.—Temperature 100·4°; pulse 124; respiration 38. Had two motions last night of the same character as the previous ones. Complains of great weakness.—Evening: Had about ten motions during the day, containing large quantities of pus; some passed involuntarily in bed. Temperature 102°; pulse intermittent and thready; respiration short and hurried. Is in a very low state. He gradually got worse, and died from exhaustion at 1 A.M. on the 9th.

Necropsy.—Liver enormously enlarged, extending upwards on the right side to the level of the fourth rib downwards three inches below the ribs. The left lobe occupied the whole of the left side, extending upwards to the fifth rib and downwards to about two inches below the level of the ribs. Heart and lungs displaced upwards. The cavity of the abscess which had been punctured by the trocar was found well contracted, but posteriorly in the right lobe there were two large abscesses not communicating with one another or the first, and filled with pus; one of these opened into the ascending colon. The liver was not adherent to the abdominal parietes, but no pus had escaped between. The liver weighed 6 lb. 12 oz.

Remarks by Surgeon-Major COLSON.—The non-subsidence of the symptoms after the abscess had been freely opened pointed to another collection of pus. I had fully determined, after an interval of a day or two, to explore for this. The appearance of pus in the stools showed it had opened into the bowel, and I had hopes that the unfavourable symptoms would subside. The result of the post-mortem examination showed that any treatment in this case was hopeless. The previous history of the case is very unsatisfactory. The patient was a German, and talked and understood English imperfectly.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Encysted and Infantile Hernia.—Imbecility with Choreoid Movements.—Treatment of Stricture of Urethra by Electrolysis.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. LOCKWOOD contributed a paper on the Morbid Anatomy and Pathology of Encysted and Infantile Hernia. After commenting upon the practical importance of the subject and briefly referring to its history, the writings of Hey and Cooper and other authorities were quoted. It was shown that the origin of encysted hernia was usually attributed to the stretching of a cicatricial membrane which was supposed to obstruct the upper end of the patent processus vaginalis. This view was rejected because—1. Such a septum had never been seen and its existence was doubtful. 2. The specimens in the museums afforded no indication that cicatricial tissue had entered into their composition. 3. Because the sac of these hernia was always composed of two layers of peritoneum. 4. Because an examination of the tunica vaginalis showed that it either communicated, in cases of encysted hernia, with the peritoneal cavity, or was simply closed by apposition and adhesion of the walls. Upon these and other grounds it was concluded that the various hernia called encysted belong, [illegible] to the infantile variety. Infantile hernia were observed to be originated by some event connected with the [illegible] tion of the testicle, which was described. It was suggested that the processus vaginalis preceded the [illegible] and that it was drawn along by fibres of the [illegible] which were inserted into it. The usual [illegible] that muscle was mentioned, but additional bands [illegible] described attached to the external [illegible] and tubes [illegible], and others were mentioned [illegible] of the processus vaginalis, with the [illegible] the peritoneum. These bands were described [illegible] cord as the "internal cremaster," and [illegible] the

Digitized by Google

looseness of the peritoneum of the back of the abdomen, the way in which it accompanied the transition of the testicle was explained. A band of muscular fibres which passed from the epididymis to the inner sac wall of the infantile herniæ was next described and identified as the upward prolongation of the gubernaculum. These fibres were considered to have much to do with the origin of the hernial sac. The results of the inquiry were: (*a*) That the London museums contain no specimens of encysted hernia such as was usually described. (*b*) That the various specimens designated by that name belong to the infantile variety. (*c*) That the latter owe their origin to the tractive power of the gubernaculum testis.—Drawings of specimens from the museums of St. Bartholomew's, Guy's, St. Mary's, and St. Thomas's Hospitals, as well as various diagrams, were exhibited.—Mr. HOWARD MARSH was not prepared to endorse in their entirety the views put forward by Mr. Lockwood, but so far as he could gather from the paper the arguments seemed sound. He confessed that he had always had some difficulty in understanding how encysted herniæ originated, notwithstanding Mr. Hey's original account of the nature of the hernia.—Mr. LOCKWOOD, in reply, thanked the curators of the various museums who had allowed him to make such free use of the specimens under their charge.

Dr. FLETCHER BEACH read a case of Imbecility with Choreoid Movements. The author recorded the case of an imbecile patient, of fairly high type, aged seventeen years, who, as the result of epileptic fits, lost some power on the left side, and after which continuous spasm of the left hand and arm was noticed. A description of the movements, which ceased shortly before death, was given. At the necropsy the parietal regions of the brain were more resistant than normal, and the occipital convolutions were firm and hard; the white matter of the first temporo-sphenoidal convolution, of the inferior parietal lobule on both sides, and of the occipital convolutions, on a level with the middle part of the lateral ventricles, appeared fibrous. The chief changes noticed microscopically were: (1) great increase in the number of the vessels; (2) distension of many of these vessels; (3) extensive infiltration of the tissue with leucocytes, especially in the perivascular sheaths of the vessels. The case was regarded as one of post-hemiplegic disorder of movement allied to those described by Dr. Gowers (Medical and Chirurgical Transactions, 1876). The difference between the symptoms noticed in athetosis and in the disease under consideration were contrasted; the essential difference being that, according to Dr. Gowers, in the mobile spasm seen in partially paralysed limbs there was a fixed spasm superadded to the mobile spasm. The pathology of the affection was then discussed. Dr. Gowers says: "The symptoms point clearly to damage to the grey matter of the brain, to local perverted nutrition of nerve cells, in consequence of which they over-act, either spontaneously or on the stimulus of a volitional impulse, which is by their over-action perverted or irregularly distributed." In the case under notice great congestion of the grey matter of the brain was present, and it was held by the author that the microscopical appearances were pathological. The theory that the nerve cells in this case have over-acted from perverted nutrition, due to excessive supply of blood, and hence the spasms, was brought forward. Mention was made of the fact that similar appearances have been noticed in the medulla from a case of hydrophobia, and to a less degree in the spinal cord from a case of tetanus.

Dr. STEAVENSON and Mr. BRUCE CLARKE contributed a paper on the Treatment of Stricture of the Urethra by Electrolysis. The more extensive use made of electrolysis in surgery and gynæcology abroad, and especially its successful employment in the treatment of stricture of the urethra, induced the authors to undertake a series of observations to test the accuracy of the reports which had reached this country. Their results bore out in every particular the successful results received from America. Electricity, on account of its power of splitting up compounds into their chemical elements, can be used as a substitute for ordinary caustics to the human body. It can be applied with especial advantage to parts difficult of access, such as the male urethra and the uterine cervical canal, and it can also be applied to these and other regions where the application of other caustics is attended with a certain amount of danger. Its effects could be limited to the points touched by the electrode. The caustic effect could be arrested or not commenced until the applicator, in the form of the electrode, was *in situ*, and the duration and extent of the caustic action was entirely under the control of the will of the operator. The treatment of stricture of the urethra by this method was the most simple and perhaps the most striking in its results, and had therefore been selected as the first on which to collect and report observations. In this paper the details were given of six cases of stricture of the urethra treated by electrolysis, the *modus operandi* was explained, the steps of the operation were given, and the advantages of this method of procedure were thus summed up: There was usually no bleeding. If hæmorrhage did occur, it was accidental, and usually showed that too strong a current had been used. No anæsthetic was required. If pain or discomfort was produced, it was trifling. The patient could, in the case of slight strictures, pursue his ordinary occupation during the period of treatment. No antiseptics were required, as the process itself was aseptic. In the majority of cases there was no contraction or return of the stricture. Eschars produced by caustic alkalies were said to heal with less contraction than wounds produced in any other way, and electrolysis with the negative pole of a battery was a means of applying the same destructive action as was caused by the caustic alkalies to parts difficult of access in a way which was impossible by any other method. Probably other chemical decompositions and combinations take place at the negative pole besides those characteristic of the caustic alkalies, but they have not up to the present time been thoroughly made out.—Mr. BERKELEY HILL said that, whilst congratulating the authors on their interesting paper, he could not accept their conclusions as quite satisfactory. Like the American cases, the cases were given in too little detail as to the existence, size, and nature of the stricture; moreover, the final results had not been yet observed. In the first case, in which the stricture had lasted twenty years, he must say that the facts related did not carry much conviction to him; there was no conclusive proof that the tissue of the stricture had been absorbed. There were many urethral impediments that were not strictures. He related a case in which there was a stricture two inches and a half from the meatus urinarius. This consisted of a nodule of cicatricial tissue on one side of the urethral wall. By means of the endoscope (which the authors did not appear to have used), it was possible to watch the action of the electricity. In his own case the point of the needle entered into the nodule and bubbles of gas made their appearance; there was no pain, except on making or breaking the current of electricity. The application was made for fifteen minutes, with the result that an increase of one millimetre in the diameter of the urethra was gained, but even this was not maintained; and after subsequent applications the stricture became more and more narrow, and had to be treated by other methods. Altogether, he felt sceptical as to the real result of this method of electrolysis.—Mr. SWINFORD EDWARDS detailed the particulars of a case of stricture which had been first under his care two years and a half ago. There were two strictures in the penile portion of the urethra, and one in the subpubic region. The deepest stricture allowed a No. 12 French to pass, and by the gradual interrupted method a No. 25 was reached when the patient left off treatment. He returned six months ago with three strictures, situated respectively half an inch, four inches, and five inches and a half from the meatus. This time he was only able to get a filiform—No. 4 of the French scale — through the deepest stricture. A No. 3 electrode was held against the deep stricture, and a current of from five to eight milliampères was employed, but there seemed to be no effect. At another sitting a No. 5 electrode was tried, and this time with apparently excellent results, so that a No. 22 steel and 24 pewter catheter could be passed after a month or so. He opined that electrolysis might prove of great value, especially for those strictures which could not be treated by Otis's dilating urethrotome, or indeed by any other reliable method.—Mr. BUCKSTON BROWNE spoke of the necessity for careful examination of urethræ and for bearing in mind the sources of fallacy. He felt quite certain that several of the cases related would not have needed internal urethrotomy, and could have been successfully treated by gradual interrupted dilatation. He remarked on the circumstance that the succeeding electrodes were larger and larger, and said that mere pressure against the face of the stricture led to temporary relaxation and a flow of urine, even though the instrument had not engaged the stricture. It was a very remarkable fact about Dr. Newman's cases

Digitized by Google

that they were all successful.—Dr. STEAVENSON, in reply, said that the electrodes used by him were entirely different from that shown by Mr. Berkeley Hill; he would expect some swelling and increased narrowing of the urethral passage after the use of such a needle. It was necessary that the electrodes should be held tightly by the stricture, and hence the use of larger and larger sized instruments.—Mr. BRUCE CLARKE in, reply, said that he was well aware of the objections that could be raised: that the urethræ were not really strictured and the cases not really cured. Some of the cases narrated certainly demanded something more than the ordinary kind of treatment, though others did not. In one of the cases eight months had elapsed since the operation, and a bullet-headed instrument passed with ease. The result was as good as that obtained by any cutting operation, but he would be loth to assert that the case had been cured until some years had elapsed. He hoped to have an opportunity of reporting the ultimate result to the Society.

HARVEIAN SOCIETY.

AT the meeting held on May 6th (Mr. Malcolm Morris, Vice-President, in the chair) the following papers were read:—

Sudden Death in Pregnancy, Parturition, and the Puerperal State.—Dr. M. HANDFIELD JONES briefly traced the history of the evidence on which hypertrophy of the left ventricle in preguancy rests, and raised the question whether this hypertrophy was ever wanting, and if so what were the results. Cases were detailed in which clinical investigation showed apparently absence of all hypertrophy, and in such patients signs of cardiac failure and insufficiency were observable; the possibility of repeated miscarriage being also referred to this cause was shortly touched upon. Attention was drawn to the close tie existing between the heart and the uterus, and the extreme probability that the return of the heart to its normal size after delivery was, as in the case of the womb, due to a gradual process of fatty metamorphosis. While under healthy conditions this process was devoid of danger, arguments were adduced to show that in some patients this process of fatty change might overstep the normal boundary, and by weakening the cardiac muscle leave the heart liable to be overwhelmed by secondary conditions insufficient in themselves to bring about a fatal issue. Cases were read in support of this view. In conclusion, some of the cases quoted in the literature of sudden death in and after pregnancy were brought forward, and the explanation given of death in the various cases criticised, with the purpose of showing that in most of these the fatal result could be more scientifically accounted for under the view already enunciated than by referring them to such obscure conditions as idiopathic asphyxia, &c.—Dr. JOHN PHILLIPS mentioned a case in which albuminuria and œdema had been present, but no hypertrophy of heart or evidence of actual renal inflammation. Premature labour had therefore not been induced. Was it always advisable to induce it where there was reason to suspect fatty degeneration during the later months of pregnancy?—Dr. CHAMPNEYS thought that the changes in the vascular conditions before and after pregnancy were not yet fully understood. Cases of true cardiac insufficiency from rheumatism were often unsuspected until pregnancy occurred. In 75 per cent. of the cases recorded by Dr. Angel Money there were murmurs of some kind, but mostly transient. Fainting and sudden death were liable to occur even without hæmorrhage, and for this reason especial care was necessary for many hours after delivery when there had been much loss of blood.—Mr. GEORGE EASTES referred to clotting of blood in the pelvic veins and pulmonary embolism, and to ruptured uterus and post-partum syncope, as other causes of sudden death.—Dr. MORTON believed that the alteration in the character of the blood had much to do with the formation of the clots referred to by Mr. Eastes.—Dr. M. HANDFIELD JONES, in reply, advocated induction of premature labour in the cases referred to by Dr. Phillips. He was not aware of the average duration of the physiological hypertrophy after delivery.

Some Practical Points in Percussion and Auscultation of the Chest.—Dr. WILLIAM EWART read a paper on this subject, prefaced by a brief description of the instruments used in percussion and in auscultation. Manual percussion, in the author's opinion, was to be preferred to the use of the hammer and pleximeter. The relative advantages of monaural and of binaural auscultation were discussed from a practical stand[illegible] Differential stethoscopy was thought to be of little value, but Dr. Ewart advocated the use of the "comparing stethoscope," an instrument differing from the ordinary binaural in possessing two chest-pieces connected with the ear-tubes by means of a four-way tube shaped like the letter X. By this instrument special facilities were afforded for the rapid examination of the chest, and for the accurate comparison of sounds heard at widely distant spots. The comparing stethoscope had been constructed by the author before he had become acquainted with Dr. Spencer's stethoscope. The priority of the latter was freely acknowledged, and a tribute was paid to its ingenious and elegant construction. The paper concluded with practical suggestions as to the methods of auscultation and of percussion, and as to the management of patients under examination.—Dr. SANSOM advocated the use of the pleximeter in percussion. He regarded the finger as the medium least of all adapted for the purpose, believing that it was nearly impossible to obtain precise outlines by its means. For his own use he had devised a pleximeter consisting of a small pillar of vulcanite furnished with flat plates at each end of different size, adaptable to broader or narrower intercostal spaces or other surfaces. By percussion with the finger the sense of tactile vibration was fully preserved, and outlines could be so clearly defined as to admit of being marked out in pencil on the chest itself.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Bacteriology.

A MOST successful meeting of the above Society was held on Friday last at the West London Hospital, at which Mr. Ballance gave a demonstration in Bacteriology. The whole of the out-patient department was utilised for the occasion, and was tastefully decorated with flowers and ferns. Upwards of sixty microscopes were arranged upon the tables for the purpose of showing the many varieties of micro-organisms which have been during recent years isolated and described. Some beautiful specimens of the bacillus anthracis were shown by Dr. Acland. In addition to the specimens, the various apparatus employed in bacteriological research were exhibited respectively by Messrs. J. Allen and Son, of Marylebone-lane, and Messrs. F. E. Becker and Co. But the chief interest was centred in the large series of cultivation specimens which Mr. Ballance had specially prepared for the meeting. Before the members dispersed, a cordial vote of thanks to this gentleman, proposed by the President, Mr. Hemming, and seconded by Dr. Thudichum, was carried unanimously; and, in reply, Mr. Ballance said that the marvellous advance which had recently been made in the subject of bacteriology had raised it unquestionably to the position of a science, which it was only true to say was almost daily increasing in importance, so much so that we were probably within a measurable distance of the time when each medical school would possess a bacteriological laboratory, in which instruction would be given to meet the requirements of an extension of the curriculum in this direction.

Reviews and Notices of Books.

The Science and Practice of Surgery. By FREDERICK JAMES GANT, F.R.C.S., Senior Surgeon to the Royal Free Hospital, late President of the Medical Society of London, &c. Third Edition, revised and much enlarged throughout, with 1090 Illustrations on Wood, mostly new and original. London: Baillière, Tindall, and Cox. 1886.

IT is now some years since Mr. Gant first presented to the profession his "Science and Practice of Surgery." Its distinguishing features, its method and style, are well known, and the reviewer of a third edition need not attempt to indicate them. Indeed, when a text-book has reached a third edition, and especially when it has had to compete with no mean rivals, the task of a reviewer is reduced to small proportions. The entire work has been revised for this edition, and a not unsuccessful attempt has been made to present to the reader the modern aspect of surgery. The mere fact of novelty has not been held sufficient to justify notice, and Mr. Gant has endeavoured to sift the wheat from the chaff, and to

Digitized by Google

incorporate in his work only what he believes to be real and substantial advances in surgical knowledge. In doing so he has of course laid himself open to criticism, for there is by no means a general agreement as to what is and what is not true progress. A new feature in this edition is a chapter on Bacteria in Surgery, contributed by Mr. Watson Cheyne. No one better could have been selected to write this chapter, and it forms a very valuable feature of the work. Indeed, we believe that nowhere else is such a practical, compendious, and useful account of this branch of pathology to be met with in the English language. The article on Diseases of the Skin is from the pen of Mr. Malcolm Morris; it bears all the evidences of careful preparation, and a thorough knowledge, not only of the subject, but of the requirements of the student. Other articles on special subjects are supplied by the same writers as contributed to the previous edition.

In turning over the pages of this work we have noted a few points in which we think it might bear improvement. Thus, for instance, on page 148, vol. i., an elaborate classification of tumours is given, in which we find melanotic tumours classed under cancers, and *not* under sarcomata; this is a mistake which would not be lightly passed over in any surgical examination conducted with any pretensions to efficiency; it is therefore a pity that it has not been corrected. There is some confusion also about the relations of sarcomata with recurrent fibroid tumours; in the classification just mentioned they are kept quite apart, but within twenty pages we find them all massed together as sarcomata. This is just one of those points on which a student needs precise and emphatic information, and he looks to his text-book to clear up ambiguous statements carelessly made, or those he meets with in older books. A similar confusion is introduced into the chapter on Diseases of Bone, in which we find a description of several varieties of cancer of bone. A brief mention is made of the fact that cancer "generally occurs in bone as a secondary formation," but the reader of the whole section would be likely to derive the impression that cancer of bone as a primary growth is well known, by no means rare, and is a disease demanding active surgical treatment. Nothing is written which even suggests that primary cancer of bone is either infinitely rare or entirely unknown. In another place we read that syphilitic sarcocele "cannot be distinguished from scrofulous." We are quite willing to admit that in some cases the distinctions between the different sarcoceles are not well marked, but the above is much too sweeping a statement.

There are passages in the chapter on Fractures which call for some remark. Here is one: "Fractures differ essentially in regard to the mode of their reparation, according as they are" simple or compound. By the way, why does Mr. Gant always speak of "reparation" and not of repair? But apart from this, we have here a statement which is seriously at variance with fact, and which is rendered more puzzling by subsequent statements. Thus, under the heading "Course and Termination" of Compound Fractures we read: "*Inflammation* supervenes, followed by suppuration, perhaps profuse, and partial sloughing; or by gangrene on a larger scale. Either degree of mortification, arising from inflammation, is limited to the seat of injury. By this process, however, a fracture, which originally was simple, may become compound in some cases." What idea this could convey to a student seeking here his first instruction on this subject we cannot conjecture. Such ambiguity not only renders the task of reading far less pleasant than it otherwise would be, but it produces a condition of bewilderment in the reader which is far removed from instruction.

Charcot's Joint Disease is not adequately described; its sudden onset with great swelling and its painless character are not mentioned. With regard to the mode of origin of loose cartilages in joints, we find in one paragraph these two statements, which scarcely harmonise:—"They seem to *arise* from the vascular processes of the synovial membrane, as outgrowths of that membrane, projecting into the joint." "Rarely, they form in the synovial tufts." In the description of Congenital Sebaceous Cysts of the Head, there is no mention made of the differences in structure, contents, or position of these cysts and common wens, which they are said to resemble. The old operation of plugging the posterior nares, fast becoming only a "relic of barbarism," is fully described as the treatment for severe epistaxis, and no mention is made of the far superior rubber air tampon, or of the fact that many cases of epistaxis can be efficiently dealt with by proper plugging of the nose from the front.

We cannot part from this book without expressing our sense of the magnitude of the task Mr. Gant set himself, and of the energy and perseverance he has brought to its fulfilment. We hope this edition will be as successful as its predecessors, and that we may soon hear that Mr. Gant is again busily engaged in revising it for a fourth issue.

Archives Slaves de Biologie. Dirigées par MM. MAURICE MENDELSOHN et CHARLES RICHET. Tom. I., Fasc. I. Paris: 111, Boulevard St. Germain. London: David Nutt.

THIS is the first part of a new journal which is intended to be the vehicle for the work of Slav biologists, who already are very numerous, and whose labours are at present only represented by memoirs scattered through French and German periodicals. The *raison d'être* of the Archives is clear. There are probably not half a dozen scientific men in England and but few in France or in Germany who can read Slav. Hence researches which have cost much labour and pains are either wholly unknown or are read only in the form of an abstract or highly condensed note, in which many important points are passed over without notice. The editors hope to be able hereafter to publish a fasciculus every month, but at present do not feel able to promise more than six parts per annum. Their intention is to translate and publish in the French language all important papers within a month after their publication, whilst in the case of less important articles a full but complete analysis will be given. Sections will be devoted to bibliography, critiques, and notes of recent discoveries in other countries. The bill of fare will include memoirs on biology, embryogeny, anatomy, physiology, histology, anthropology, zoology, and palæontology, together with physiological chemistry and physiological psychology. The present number contains many (fifteen) original memoirs and many critiques and analyses. Amongst these are a note by Fritsch on a human cranium found in the clay of Podbaba near Prague; a contribution by Godlewski to the theory of the circulation of the sap in plants; papers by Pocta and Werzejewski on the development of fossil and recent sponges; Lesshaft on compound joints; Kowalewsky on the nervous mechanism effecting dilatation of the pupil; Navalichin on the growth, development, and death of muscular fibres; Botkine on pernicious anæmia; Kourloff on the alimentation of phthisical patients; and Oberzut on the morphology of the bacilli of tubercle: altogether a very satisfactory list for the first number of a new journal, to which we wish all success. The papers are all in French.

Notes on Analytical Chemistry, for Students in Medicine. By ALBERT J. BERNAYS, Ph.D., F.C.S., F.I.C., Professor of Chemistry, Practical Chemistry, and Toxicology at St. Thomas's Hospital Medical and Surgical School, &c. Second Edition. London: J. & A. Churchill.

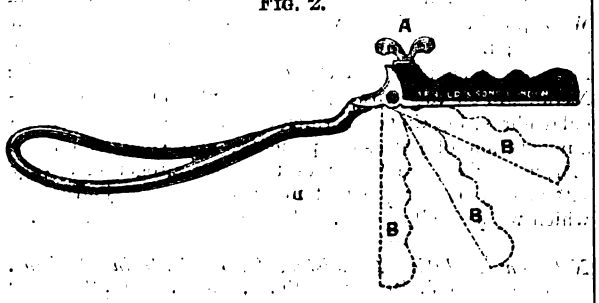
THE modest title of Dr. Bernays' little book scarcely does justice to it. Although exceedingly condensed, it is sufficiently detailed to guide the student through his practical work with little assistance from the teacher, and clear expositions of the nature and cause of the

Digitized by Google

reactions concerned are uniformly given. Although it is intended to help students in preparing for the London University and other examinations, it is no mere cram text-book. The time that can be devoted to chemistry by even the most diligent student is very limited, and it is important that it should be judiciously expended. The book with which he works should contain little more than his real requirements, but should provide completely for them. This is exactly what Dr. Bernays has done, and medical students may be grateful to him for his work. In a space of about 130 pages he has given a progressive series of practical studies, commencing with very simple analysis, but including the examination of a certain number of organic compounds, the elements of volumetric analysis, some physiological chemistry (including milk, bile, urine, and blood), the rudiments of toxicology, the examination of water, and many other matters of which some practical knowledge is now required for the higher examinations. Altogether, the book, though so small, is good and useful.

New Inventions.

A MODIFIED MIDWIFERY FORCEPS.



I WISH to bring under the notice of the profession a midwifery forceps which I think will fulfil (1) an indication for which much more elaborate, and, to say the least, terror-exciting instruments are from time to time brought out; (2) to meet a difficulty which is recognised, but for which no mechanical contrivance that I am aware of has been proposed; (3) to fulfil still another defect which is rarely considered by operators. It may be thought presumptuous to suggest anything further in the way of a midwifery

FIG. 1.

forceps, whose name is legion. I, however, propose a modification only, which I have found useful in practice without being elaborate or complicated. If unskilful surgeons require skilful instruments, then the sooner some medical men get them the better! All cannot be Simpsons in midwifery or Thompsons in lithotrity, and whoever strives to perfect diagnosis and treatment by the perfection of instruments with a conscientious and not ambitious object tends towards the general good as much as the skilful surgeon who works skilfully with unskilful instruments. Fig. 1 shows the handles bent back to meet the line of axis run-

FIG. 2.

ning through the fenestral, and by so doing dispenses with the aid of a traction force applied to the blades. Such a bend makes the instrument also easy of introduction, and keeps the handles in proper place when introduced. The non-recognition of this simple fact in the ordinary forceps has long kept in use a most unscientific instrument, whose axis is altogether erroneous. Contrivances have of course latterly been used to meet this difficulty, but in my opinion are not simple enough, or are too elaborate or bulky. Fig. 2 shows the chief advantage I claim for the instrument—viz., the presence of a screw hinge on the upper blade, which will make it easy of application, and fulfil an indication for which there is no provision at present made—i.e., the adaptation of the space between the blades to the varying size of the child's head; I think it very strange to squeeze the head of every child delivered by forceps to the same extent, and the evils ensuing therefrom, though not apparent, are nevertheless real. I wish to add my testimony to that of others in favour of the forceps being a more safe and desirable aid to delivery than is generally thought, not only in inertia, but where force and the obstacle of an unassisted process cause prolonged suffering, and weary both uterus and patient. With rather thin and well-shaped blades little or no bulk is added to the presentations, whilst the broad body formed by the head is changed into, as it were, a moving inclined plane, which, even without traction, slips out more easily than if left to the process of nature, and in my experience does more than almost anything, combined with the injection of oil, to save the perineum. We shall always, of course, have Radicals and Conservatives in medicine, but he who nowadays watches the wearisome process of prolonged labour in women whose tissues are weakened by the acquired and transmitted debilities of modern town life, with perhaps an increase rather than otherwise in the size of heads, will be more often conscientiously urged to supply a wanting balance in the shape of instrumental aid, but gently, slowly, and scientifically applied and used. The forceps have been contrived by myself and Mr. Arnold of Smithfield, to whom I am indebted for this and for other aid.

JAMES MACMUNN.

Finsbury Park, N.

THE PRESENT SYSTEM OF MEDICAL EDUCATION IN LONDON.

To the Editor of THE LANCET.

SIR,—Dr. Moxon's letter and the reply to it by Dr. Hood have a deep interest for the great majority of practitioners of medicine who have received their professional education in London, and also for metropolitan students in the present and future. As a general practitioner, I tender Dr. Moxon my warmest thanks for using his powerful pen and still stronger influence in endeavouring to obtain a degree for physicians and surgeons of the London Colleges. Why the hundreds of our best practitioners who have never had a degree should, as Dr. Hood asserts, degenerate to third-class men on receiving it I cannot see. Does Dr. Hood apply his dictum to the possession of any degree? Success in life does not, happily, depend upon having a degree, as the writer can testify; but it is not pleasant to be surrounded by Scotch and Irish graduates who pose before the public as holders of a superior, because a higher-sounding, qualification. Medical practitioners are not unfrequently consulted by parents on the question of professional education of their sons, especially with reference to the selection of a medical school. After explaining the disabilities under which metropolitan students suffer, I am compelled to advise the sending of them anywhere rather than to a London Hospital, unless they are prepared to put their sons through the long and weary work requisite for the obtaining of the London degree along with the many chances of failure before them. There should certainly be no longer any delay in putting London educated practitioners and students on a titular par with those of the north of England, of Scotland, and of Ireland. If this is not speedily done, not only will the London schools be more and more avoided by students, but the degree-granting institutions will be so crowded that the comparatively small clinical advantages belonging to the latter will become less available.

I quite agree with Dr. Hood that science should be taught at science schools; and I believe I am right in saying that advances have been made from St. George's Hospital to South Kensington for the carrying out of this object. For many reasons I think "Westminster" would be far preferable to "Albert" as a name for the new degree. The two following may be mentioned. "Albert" gives no idea of locality, and would necessitate a further affix of "Lond.," which would be an injustice to the holders of the veritable London degree; whereas "Westminster" at once localises and gives the prestige of antiquity to the degree.

I am, Sir, yours obediently,

May, 1886. PHYSICIAN AND SURGEON.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, MAY 29, 1886.

THE Contagious Diseases (Animals) Bill has again been introduced, and will, it is hoped, pass into law before the close of the present session. Whether this success will be attained, or whether, as in the case of its predecessor of last year, it will be included in the long list of legislative measures which are sacrificed by an abrupt termination of the session, the next few days will probably show; but it deserves greater consideration than before, if for no other reason than the hope which Mr. W. H. POWER'S recent investigations have raised that some really practical steps may be taken to prevent the disasters which now result from the distribution of infected milk.

With the greater part of the Bill we need not now concern ourselves; it relates to the amendment of the provisions of the Act of 1878, which have as their object the limitation of foot-and-mouth disease; but it also evidently intends that the whole subject of milk infection shall be considered in relation to the health of human beings, and therefore proposes that the powers vested in the Privy Council by Section 34 of the former Act shall be transferred to the Local Government Board. Under this section the Board will be empowered to make special or general orders for ensuring what is usually understood as the sanitary condition of dairies and cowsheds, and the cleanliness of milk stores, milk shops, and vessels used for containing milk for sale; and also for the inspection of cattle in dairies, and for prescribing precautions to be taken for protecting milk against infection or contamination.

The Privy Council have interpreted these precautions against infection to extend to the circumstances of the milk after it has left the cow, and have assumed that any infection from which it may become contaminated must necessarily be infection derived from some human being the subject of disease. Hence the precautions thus prescribed are those which would prevent infectious persons coming in contact with milk or taking part in the business of dairyman. Recent experience has shown the insufficiency of these precautions. That they may have a value we are prepared to admit; as against dissemination of enteric fever they are calculated to eliminate one very probable source of contamination, and even the infection of milk by scarlatinal virus communicated in this manner cannot but be regarded as within the bounds of possibility. But medical knowledge has, thanks to Mr. POWER, gone beyond this, and we are already led to see that the contamination of the milk against which precautions have to be taken may occur either before or at the moment the milk leaves the cow. The exact nature of these precautions cannot at once be seen; it may be hoped that they will, however generally, be apprehended before the lessons to be learnt from the Hendon farm are forgotten; and it may be assumed that they are essentially those which relate to the cow herself. We trust this is sufficiently appreciated by those responsible for drafting the Bill which is now before Parliament, and that all the necessary powers are being conferred upon the Local Government Board which can now be perceived to be necessary, and which may be more fully required as additional knowledge of milk infection is gained.

In view of the need for medical supervision of every detail connected with milk production and supply, it is somewhat surprising to find that, while the various sanitary authorities throughout England and Wales are to be entrusted with the administration of the Act, the metropolis is to be treated exceptionally. There can certainly be no desire to overlook the medical aspects of the subject, and we can but attribute the decision to continue the Metropolitan Board of Works as the local authority for all parts of London, except the city, either to the fact that the vestries and district boards have lost public confidence, or to the distinct advantage which results from entrusting these duties to one board having jurisdiction over the whole metropolis, rather than to thirty-nine district authorities. If the Bill is not to be amended in this particular, the metropolitan local authority must be provided with the organisation necessary to enable them to perform these difficult duties, and it would be certainly well if the Bill required them to take the steps required for this purpose. But the metropolis is in an unfortunate position with regard to its ability to guard itself against the dissemination of disease through infected milk introduced from without. It is dependent in a very large degree upon the efficiency of provincial local authorities, and over these it can exercise no supervision. Everything will therefore depend upon the thoroughness with which the Local Government Board watches over the action of these bodies. The making of proper regulations is a matter very different from their enforcement, and this duty of the Central Board should be undertaken with energy for the reason that the effects of any negligence will often not be appreciable in the district whose representatives will be responsible for the administration of the law.

THIS year the lectures at the College of Physicians illustrate the tendency in the mode of advance of scientific medicine. The Croonian and the Lumleian Lectures both dealt with scientific matters in a manner which none but scientific men could hope to understand in its entirety. In this regard we may perceive good grounds for the training in chemistry and physics, which should form part of the education of every physiologist and true pathologist.

The key-note of Dr. STONE'S most able and successful lectures is very soon struck: physics, and without them nothing. There is a radicality in this method of dealing with the electrical conditions of the human body which to the logical mind commends itself as of the most philosophical and rigidly exact kind. Like all genuine advances, the Lumleian lecturer's position tends to displace much that was fascinating but incorrect. He insisted upon the great importance of absolute measurements of electrical currents. Professor HUGHES having shown that the telephone can be used for the estimation of electrical currents, Dr. STONE immediately takes up the idea and uses it instead of the unmeasurable and entirely empirical indications of the galvanoscopic frog. Perhaps the chief fact that the lecturer gave his audience was that concerning

Digitized by Google

the estimation of the resistance that the human living tissues offer to the passage of electricity. For the first time in medical electricity we think it may be definitely admitted that the resistance has been accurately ascertained to be about 1000 ohms. This estimate is of the tissues without the skin. The latter is a most perfect insulator of enormous resistance, hence the previous overestimation of the resistance. But it was shown that by employing very large areas of contact and freely wetting the skin, its resistance could be eliminated. As having a direct bearing on medicine, the alterations of the resistance that take place in disease are especially interesting. In dropsy, it was found that the resistance was diminished; in one instance, as Dr. STONE ascertained, even to one-half. In six cases of hemiplegia with contracture the resistance was much less on the paralysed side of the body. Again, in impregnations of the tissues by various metals the electrical resistance was much altered; mercury had a decided influence in diminishing it, as also had copper, whilst the influence of lead was but slight.

The human body, like any fluid or body holding fluid, acts as an electrolytic agent. Certain chemical decompositions take place, and this is the equivalent of a development of electricity; electricity therefore begets electricity. By employing electricity as a curative agent Dr. STONE was able to make observations in certain cases of disease. In a case of old-standing sciatica with wasting of the leg, and in two of diabetes, it was found that by charging the body with a moderate strength of constant current for half an hour a considerable discharge took place from the body, which might last for several hours. The first and largest discharge that occurs after the body has been charged is probably to be accounted for as a phenomenon of self-induction; but the less marked though longer discharge is most probably due to electrolysis.

Most elaborate explanations have been offered concerning the phenomena of electrotonus, and one of the most revolutionising parts of Dr. STONE'S lectures was concerned with it. Science is measurement, and the latter is what Dr. STONE pleads for. He says in effect: "Let us have our groundwork sure; let us be quite certain what strength of current is being used; let us ascertain the resistance and polarisation of every wire and every part of the circuit, whether composed of dead or living matter, before we venture to think we understand the phenomena over which physiologists have laboriously pondered and too often ingeniously misinterpreted." Even if Dr. STONE'S arguments did not appeal to one's instinct for science and truth, which they undoubtedly do, he has at command *a posteriori* evidence of the importance and absolute necessity of his scepticism. In the experiment shown with telephones it was demonstrated that on making and breaking the current the telephone clicked; it, a purely physical instrument of research, gave a loud click with the break, and a softer sound with make. On withdrawing the coil along the slide, just as was done when experiments in physiology were made, both clicks grew fainter, until the softer disappeared. Just as in experiments on nerve-muscle preparations, the telephone reproduces the peculiar difference between make and break,—a difference which in neuro-muscular physiology is ascribed to vital conditions. In the third lecture it was shown that induced currents could be measured, and that the resistance of the human tissues to them was much less than to the constant current. It would seem as though the induced current penetrated with the facility of a conical bullet as compared with the constant current, which rather resembled the slower penetration of the spent round ball. The human body, like all imperfect conductors, is probably more permeable to high-tension than to low-tension currents. As the lecturer urged, there is a great field open for research in physiological electricity, which, though a stately building, rested still on an unsafe foundation or *physical basis*.

THE questions recently asked in the House of Commons as to the prevalence of small-pox at Wooburn in connexion with the paper-mills in that place again give prominence to a subject which has from time to time received more than passing attention. The influence of the rags which are used in the manufacture of paper as vehicles of disease is distinctly recognised by all authorities on public health; and as regards one infection, that of cholera, the State steps in to secure the community from risk by the issue of Orders prohibiting the importation into England of rags from countries where that disease prevails. It is true that little is known which could prove the existence of actual danger in the case of cholera, whereas one of our current infections—namely, that of small-pox—has again and again been communicated through the agency of rags, and the rag-sorters in paper-mills being first affected, the disease has spread to those with whom they associate. This is what occurred when a sudden outbreak of small-pox took place amongst women employed in the St. Mary Cray paper-mills, and the same has occurred again at Wooburn; and the public somewhat naturally ask, both in and out of our Houses of Legislature, whether something cannot be done to protect the public from the danger that ensues.

A distinction has always been drawn between the importation of diseases foreign to our climate, such as cholera, plague, and yellow fever, and those which we have always with us, in so far as legislative interference is concerned; and we are bound to admit that, so long as small-pox is one of our current infections, it would hardly be possible to prohibit the importation into one district of rags from another district where small-pox happened to prevail, except in so far as it might be practicable to offer proof as to the actual infectiveness of any given bales. But, assuming that there must be free trade in rags in so far as the manufacturers are concerned, it becomes a question whether the rags ought not in all cases to be subjected to some process of disinfection before they are used for the purposes of any manufacture, whether of paper or otherwise. And the question is the more pressing because there is reason to believe that some rags from abroad come from such institutions as hospitals. But considerable difficulties stand in the way. There is, under the Public Health Act of 18[illegible], a legal remedy against any person who gives, lends, sells, transmits, or exposes without previous disinfection any bedding, clothing, rags, or other things which have been exposed to infection from any dangerous infectious disease. But, apart from a detailed knowledge of the history of the bale or parcel of rags, it is impossible to say that [illegible]

Digitized by Google

or more samples have been so exposed; and hence, as a matter of fact, no remedy lies against the manufacturer. Indeed, it might be unfair to hold him solely responsible when, as a matter of fact, no practicable check can be, or is, placed on the proceedings of the original owner of the rags, or upon the marine store dealers who collect them in the first instance.

There are, however, two definite remedies. One lies in the disinfection of all rags before they are unpacked for sorting purposes. This action must, however, in the present state of the law, be purely voluntary on the part of the paper manufacturers; but it may be hoped that, with the machinery and steam power which are available in every paper-mill, the time may come when the cost of applying steam under pressure to all cargoes of rags may be effected so rapidly and economically that it will generally be resorted to. The other lies in efficient vaccination and revaccination both of the workers in the mills and of the surrounding communities. This latter remedy can easily be applied by all who have sufficient common sense to appreciate its protecting value, and manufacturers can use their influence to secure its practice amongst their *employés*. Small-pox is the only infectious disease against which there is an easily available and trustworthy means of protection, and its prevalence, whether in a paper-mill or elsewhere, points to the neglect of a simple and efficient remedy.

AT the time of our going to press the Medical Bill is precariously situated. The lukewarm character of the Bill, and the belief in every medical body that it and all its interests will survive under the measure, disarm opposition. However, we again cheerfully and gratefully admit that Sir LYON PLAYFAIR has shown a very courteous disposition to consider objections, and especially our own objections, to the obtrusion of the Privy Council at every stage of the work of the General Medical Council; to the inadequate proportion of direct representatives (especially for England) to the other constituents of the Council; and to the monstrous proposition that the Privy Council should have the power of ordering the Medical Council to register foreign graduates of whom and of whose degrees the Medical Council may disapprove. Sir LYON PLAYFAIR is understood to be ready to modify the clauses bearing on these points. He is prepared to give five direct representatives, and in certain eventualities a sixth. He will erase in many places the words requiring the sanction of the Privy Council, and in the serious matter of recognising foreign degrees he is willing to show more respect to the Medical Council. So far, so good. But all interested parties should use due vigilance. No one can visit the House of Commons in these excited days without feeling what a game of chance legislation is, and how slight and superficial is the remedy that even a Government can apply to the greatest evils. The forms of Parliament have been the death of many a Medical Bill. They prevented progress in committee on Monday night, when Sir LYON PLAYFAIR was hopeful of getting it practically through its committee stage; and he would be a sanguine man who in such a time of crisis and political tension as this would confidently expect a Bill to pass of which members of Parliament know but little and care even less. The intervention of the Medical Council to preserve the independent government of the profession would be of course most desirable; but by the time that body, which meets next week, shall have decided to intervene, the deluge may have come and swept the authors of the Bill away or it may have slipped through its remaining stages into existence. Meantime we must trust to the reasonableness of Sir LYON PLAYFAIR; and we must be grateful, as we are sure the profession will be, to Dr. FOSTER, who has most actively studied the Bill and all proposals of modification, and to whom, indeed, we owe many valuable amendments, especially that for the increase of the number of direct representatives.

There are still three great evils that are not touched by the Bill as it stands, and the non-removal of which will make any Bill a poor contribution to the solution of the problem of medical reform. We can only indicate them for the consideration of Sir LYON PLAYFAIR, or Dr. FOSTER, or any other member who will rise to the height of this great reform. The three evils which will remain are:—

First. The multiplicity of licensing medical authorities which will continue to compete with one another and to disparage each other's examinations.

Secondly. The undignified competition of degree-granting bodies with diploma-granting bodies.

Thirdly. The comparative impunity of medical practice by unqualified persons acting either alone or under cover of registered practitioners.

To say that such evils will remain unremedied under the Bill is to pronounce the most severe condemnation of it. But we must say what we feel, and we shall be glad if the author of the Bill or any of its critics can contrive, even at the eleventh hour, to make it really worthy of the profession whose efficiency it is to regulate, and of the public whose highest interests it is meant to serve.

Annotations.

"Ne quid nimis."

HER MAJESTY THE QUEEN.

IT is a subject for congratulation among all classes that Her Majesty has reached her sixty-seventh birthday in good health and with more than average constitutional vigour. The many years of retirement which followed the great grief which befell her in middle life seemed to thrust upon her a life of seclusion and sadness. It has happily been broken somewhat of late, much to the satisfaction and pleasure of Her Majesty's subjects, and we trust and feel assured with no injury to Her Majesty's health. It, however, must have been a considerable effort to reappear in public, and nothing but a deep sense of duty could thus have aroused anyone. Something is due to the judicious care with which Her Majesty has been tended, and we may take it as an expression of gratitude to our own profession that the first act performed by Her Majesty in public was to lay the foundation stone of the new medical buildings now being erected conjointly by the Royal College of Physicians and the Royal College of Surgeons. The kindly expressions on that occasion towards Her Majesty's physician were very grateful to the whole profession as an honour done to their highest representative in his capacity of President of the Royal College of Physicians; and the title offered to the President of the College of Surgeons on that occasion, though declined by

Digitized by Google

him, was not less grateful to the profession; for Mr. Savory is the premier of the great body of practitioners of the country who claim allegiance to the Royal College of Surgeons, and any honour done to him is in reality done to them through him.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON.

AT an extraordinary meeting of the College on the 20th inst., the gentlemen elected at the last Comitia were admitted Fellows. The list, which has already appeared in our columns, this year was below the average in point of numbers, but was certainly strong as regards individual quality. Taking the whole list, especially with respect to the metropolitan members, the election this year has been most satisfactory. There has been less evidence of favouritism and a more liberal recognition of individual work. If the same care continues to be exercised, the Fellowship will once again take the high position with the profession and the public which it occupied in the palmy days of the College, when it was the mark of sterling achievement, and not the reward of mere success in practice. In making these remarks, we are aware that there is a very considerable number of Members of the College of old standing who feel aggrieved at being passed over, and who urge that they ought no longer to be ignored. No doubt cases of individual hardship in this respect do occur, but we believe them to be very rare, and hold it to be quite exceptional for good, sound, honest work to be permanently overlooked; and in London, where the line between consultants and practitioners is so rigidly drawn, we feel convinced that the Fellowship ought not to be granted except to those engaged in teaching in the schools or in original research. Even in the provinces the same rule should hold, and the Fellowship should be the reward of work, and not bestowed on account of wealth or of political or county influence. The list this year has been so good and so much in accordance with what we have for many years insisted on that we hesitate to add anything like criticism. But if there is a shortcoming, it is in the somewhat illiberal treatment of the provincial Members. Two or three names of physicians belonging to provincial schools have occurred to us who ought to have been among those recently elected, since their work is well known, and stands as high as that of any in the list. Our provincial schools are year by year increasing in size and influence, and we sincerely hope the present oversight is not occasioned by any feeling of jealousy. Such ought not to be the case; the College should view with pride the work of its provincial Members, and admit them to a full share of collegiate honours.

THE VACANCY IN THE SENATE OF THE LONDON UNIVERSITY.

THE election of a member of the Senate of the London University will take place on the 29th prox. Dr. Wilks and Mr. Magnus have been nominated as candidates for the vacancy, and the name of Mr. Thiselton Dyer has also been mentioned as a probable candidate. On Dr. Wilks' qualifications for this post it is unnecessary to dwell. His services to the cause of medical education and literature, his hearty aid to all projects for the improvement of the profession of which he is an honoured member, are too well known to need recapitulation. We are informed that the names of 200 graduates, including the most eminent members of the Medical Faculty, have already been received in his support. Mr. Magnus will be also known to our readers. He contested the last vacancy with Professor Carey Foster on the strength of his B.A. degree, and has of late made himself conspicuous by his action in regard to the reform of the University of which he now seeks to become a governing member. Coming forward to contest the present vacancy on his B.Sc. degree, and thus breaking the spirit, if not the letter, of the understanding that the seats of Convocation on the Senate alternately belong to the Arts and Laws Faculties on the one hand, and those of Science and Medicine on the other, it is to be hoped that Dr. Wilks will have a majority of votes sufficiently large to convince even Mr. Magnus that it is not well to attempt to run with the hare and hunt with the hounds. Moreover, the recent losses of Drs. Storrar and Carpenter have seriously diminished the strength of the medical representatives. The election, as already stated, will take place on June 29th, and voting papers are to be delivered personally to the Clerk of Convocation or sent by post at least one week before that date.

TRANSMISSION OF TUBERCULOSIS TO CHILDREN.

AT a recent meeting of the Boston Society for Medical Improvement, Dr. Gannett read a paper with the title "Should Nurses who are Tuberculous be allowed the care of Children?" (*Boston Med. and Surg. Journal*, April 29th.) Premising that he was not speaking of wet-nurses, and giving a slight sketch of the doctrine of the transmissibility of tuberculosis as raised in the bacillary hypothesis, he proceeded to relate two cases of fatal tuberculosis in children of previously good health and without hereditary predisposition, both of whom had been under the care of nurses who were tubercular. One was a child four years and eleven months old, who died from tubercular meningitis after a three weeks' illness. In addition to the appearances of general acute miliary tuberculosis, there were foci of chronic tubercular broncho-pneumonia and also chronic tuberculosis of the bronchial glands. There was no family history of tubercle; the child was born healthy, and was nursed by the mother until nine months old. At the age of fourteen months the child came under the care of a nurse about twenty-six years old, who had lost one sister of consumption, and was herself pale, but of healthy appearance. The nurse remained in charge for a period of three years and five months, and when the child was four years and two and a half months old it slept with her at night as well as being in her care during the day. About this time symptoms of phthisis developed in the nurse, and she had eventually to give up her situation from increasing weakness, four months before the child fell ill. It is possible that the child was infected through the lungs, which showed evidence of more chronic disease than other organs. The second case was that of an infant eighteen months old, who also died of meningitis, and in whom caseous nodules occurred in the lungs and bronchial glands, which contained tubercle bacilli. The only case of tuberculosis on the father's side was that of a great-aunt, who died of this disease after nursing her husband for the same affection; and on the mother's side a cousin had died of phthisis. The child in question was the youngest of three; its nurse, a Scotchwoman, twenty-two years old, was subject to colds and coughs, and developed signs of phthisis. She was in charge of the child for eleven months, from the age of six weeks. Dr. Gannett did not desire it to be thought that these cases proved that the children were infected by their nurses, but that there was "sufficient probability of such infection as to render it important for physicians to caution the laity about allowing children of a tender age to come into too close or frequent contact with nurses and others who are tubercular." In the debate that followed Dr. Minot thought there could be no doubt that the children were infected as stated; but he could only recall one case of such a form of infection—viz., in the wife of a gentleman in the third stage of phthisis. She developed the disease, having no hereditary ante-

Digitized by Google

cedents. Dr. Rotch, who had seen one of the cases related by Dr. Gannett, said there was certainly a remarkable coincidence in the tuberculosis of the nurse and child, but did not think it justifiable to say that there could be no doubt of infection. He pointed out how frequently tuberculous mothers lived in close contact with their children, who never showed any signs of infection. He thought it prudent, however, to exclude children from the care of tuberculous nurses. Dr. Fitz agreed on this point, owing to the probability of such a medium of infection, remote as that probability may be. Dr. White spoke in the same sense, and Dr. Bowditch declared that he had held phthisis to be contagious under favourable circumstances long before the bacillus was discovered.

THE THROAT HOSPITAL, GOLDEN-SQUARE.

THE dispute at the Golden-square Hospital, which has ended in the resignation of all but one of the members of the staff, appears to have had its origin in the interference by the managing committee in a question which, though small in itself, strikes at the root of the proper relations of the medical staff to the hospital. A resignation having created a vacancy in the days of seeing patients, the managing committee filled up that vacancy without previous consultation with the medical council. Then followed protests, recriminations, and finally a general resignation, with one exception, on the part of the staff, who considered justly that their rights had been infringed. The history of the whole matter, which extends over several months, is embodied in a lengthy document issued to members of the committee by the medical council, after their failure to get their grievance redressed. Although the domestic concerns of the Golden-square Hospital cannot be deemed of much general interest, yet whenever there is a conflict between a hospital staff and its managing committee it is important to investigate it for the sake of other institutions in which such a constitution is found. In 1877, owing to irregularities in management of such a character as to lead to the withdrawal of patronage in high quarters, the medical affairs of the hospital were placed in the hands of a council consisting of the acting and consulting medical officers. In 1883 the dean of the medical council was given a seat *ex officio* upon the managing committee, and the only other medical officer who has a seat on that committee is Dr. Morell Mackenzie, who also, by virtue of his position on the consulting staff, is a member of the council. In the present dispute Dr. Mackenzie appears to have taken part with the committee as against the views of his colleagues, who represented the medical council. The *casus belli* was the following: On January 26th last, within an hour of the meeting of the committee, the chairman persuaded Dr. Semple to resign his appointment on the staff, by reason of age and length of service. Had Dr. Semple declined to accede to this request, until, at least, he could have consulted his colleagues, the friction which arose might have been avoided. However, his resignation was received, and Mr. Hovell was nominated by the committee to fill the vacancy thus created. A protest from the dean against this undue haste led to the appointment of Mr. Hovell being held over until, according to custom, the day vacated by Dr. Semple had been offered to members of the staff in order of seniority. Unquestionably the committee acted in violation of precedent in not notifying the fact of Dr. Semple's resignation to the medical council, and asking that body to take steps to fill the vacancy. Nor in yielding so far as to offer to the senior physician the choice of the day so vacated did the committee wait to receive the advice of the council, for when Dr. Prosser James declined to accept the offer because the council had not been consulted, and when the next in seniority, Dr. Whistler, withheld his answer until the council had met, the managing committee without further delay proceeded to the appointment of Mr. Hovell. It is needless to pursue the steps of the controversy further. The council endeavoured, without success, to get a reasonable hearing or discussion of their grievances; their protest that the appointment of Mr. Hovell by the committee, without previous consultation with the medical council, was illegal was disregarded, and they acted very properly in sending in their resignations. The members of the staff have done right to protest against an unwarrantable attempt to ignore their advice in questions relating to their offices, and we are glad for the sake of the profession that they have had the courage to pursue their protest to its legitimate conclusion. Had they taken the same course nine years ago, the history of the hospital would have been different; but they then allowed their scruples to be satisfied with the formation of a medical council, which, it appears, is only a council in name and not in fact. The plea that it is the duty of the managing committee to arrange the days and hours of the attendance of the medical officers, and to see that this attendance is punctually made, cannot apply to the present circumstances, which involve—first, the occurrence of a vacancy; and, secondly, the selection of an officer to fill that vacancy: matters which, if there be a medical council at all, are precisely the questions with which they should be expected to deal, and upon which their advice undoubtedly should be sought.

FEAR AS A PATHOLOGICAL FACTOR.

IN the summer of 1884 Professor Mosso of Turin published his brilliant monograph "Sulla Paura" ("On Fear"), just in time to admonish the profession in Italy of how seriously that depressing emotion can intensify the ravages of such an epidemic as cholera; and now we have the same treatise, admirably translated into French by Felix Hément, justifying its reappearance by the renewed outbreak of that disease. There is much, however, not only of opportune but of permanent interest in the volume. The infusion of terror into the young growing mind—so frequent a resource in the nursery, and even, in different forms, in the schoolroom—is gravely censured by Professor Mosso in a special chapter on fear as a force in education. "Everything gruesome, terrifying, panic-striking, that is said or represented to the child is a thorn left in its moral tissue to wound it throughout life. Alarm, dismay, fright, cleave for ever to the memory, like a fatal creeping plant inwoven around the reason." And he infers the damage done by this means to the tender brain of the young from the paralysing effects of such moral reagents on the adult. Examples of the fatal effects of fear in these latter cases are vividly presented in his pages, and he even coincides with the late Sir James Simpson in deducing from the depressing moral atmosphere of a hospital the argument in favour of rendering surgical assistance at the domicile rather than in the ward. Fear, he maintains, not only aggravates but engenders disease; while Bosquillon goes so far as to say that it, and not the bite of the mad dog, is the only cause of rabies. Guy de Maupassant has quite lately defended the same thesis; and Professor Mosso himself records the case of a physician who, when called in to a hydrophobic patient in one of his convulsive seizures, examined the sufferer with special care, pressed his lips to the froth-sprinkled mouth, and assured him that his malady was not rabies; no other paroxysm supervened, and the patient recovered. Twelve years ago, in Paris, a poor woman, by trade a vendor of small wares, was bitten by a dog, undoubtedly rabid, near Notre Dame, and taken to the Hôtel Dieu, where the wound was at once cauterised. Several months after she was recognised in the street by a student who had seen her under the operation:

Digitized by Google

"Tiens," he exclaimed, "vous n'êtes pas morte? Le chien qui vous a mordue était pourtant enragé." The poor woman, dismayed, was soon afterwards seized with pharyngeal spasms of the most violent kind. Admitted, *d'urgence*, to the clinique of Dr. Bucquoy, she was put under treatment, but without avail, and died soon afterwards. The case, as it occurred, was recorded and commented on at the time in the *Gazette des Hôpitaux*. The dramatic interest of Professor Mosso's work, which loses nothing in the French translation, might be illustrated by many an excerpt; but its value has another and sounder basis. The physiological study of the effects of fear on the viscera, and secondarily on the nutrition of tissue, is a meritorious specimen of scientific induction, and prepares the mind for a prompter acceptance of conclusions which would otherwise have seemed accessible only by the "high priori road."

GARIBALDI'S BODY-PHYSICIAN.

DR. BERTANI, the organiser of Garibaldi's field hospitals, has within a fortnight been followed to the grave by a scarcely less interesting figure, Dr. Giovan Battista Prandina, the General's body-physician. This accomplished practitioner and intrepid patriot was born in Milan in 1816, and was already in great request by a wide *clientèle*, when the upheaval of 1848 drew him, like so many other generous natures, into the struggle for Italian unity. He first served under King Charles Albert, and shared with him and young Victor Emmanuel the dangers and disasters of the campaign that closed in 1849 at Novara. He again resumed active professional work, this time at Chiavari, labouring assiduously among the poor of the district, and so distinguishing himself by his devotion during the cholera epidemic of 1857 that his services were recognised by two gold medals for "valour as a civilian." Two years thereafter he accompanied the Piedmontese troops on their triumphal entry into Milan, having served on the army medical staff as Garibaldi's physician, in which capacity he so won the confidence of the General that he was his constant attendant on all his Italian campaigns. In 1862 at Aspromonte, and, later, in the prison at Varignano, at Spezia, and in the islet of Caprera, he never left the side of his illustrious chief so long as the physician's art could cure or could comfort. Again he was drawn from general practice by the campaign of 1866, and again he was of great assistance to Bertani in organising the field hospitals; and a year later we find him, in the desperate invasion of the States of the Church, rendering active service under fire at Monte Rotondo, and even reinforcing the combatants in their Parthian retreat at Mentana. After this campaign he once more resumed professional work, chiefly among the poor, helping forward by his medical skill or his pecuniary means every institution for their well-being, moral and physical, while always keeping himself informed as to every phase of the declining health of his beloved General. Thirty-six is the number of the institutions, benevolent and patriotic, of which he was a steady promoter, and at whose anniversary meetings he was always an idolised assessor. On the death of Garibaldi at Caprera, in the June of 1882, he produced the General's will, which had been secretly confided to him in 1877, according to which the mortal part of the illustrious deceased was to have been consumed by cremation. But the document was not respected, Dr. Prandina's protests were overborne, and he retired from the island in just indignation at the authors of the counter-plan. This pro- [illegible] devotion was still as strong as ever—though [illegible] and a much-tried [illegible] warned him [illegible] there I shall either be quite cured or get buried in the lake"). At first the change seemed to answer; but the slight return of strength seduced him into going out of doors: the day was treacherous; and, a relapse supervening, he died serenely on the 15th inst.—the day on which, seventy years ago, he was born. His funeral was one of the most impressive witnessed of late years; and over his grave, to an audience composed of thousands of humble witnesses to his benevolence and skill, the poet and publicist, Felice Cavallotti, delivered a splendid discourse on this physician, now laid so honourably to rest.

SANITARY REORGANISATION IN MARYLEBONE.

AN important step is being taken in Marylebone with a view to the reorganisation of the sanitary department, which has not, according to public opinion as recently expressed, been maintained at a proper standard. A committee was appointed to report on the subject, and, with one exception, all their recommendations are to be carried out. The first relates to the registration and supervision of sub-let houses. As an experiment, 150 of these houses were registered shortly after the outcry against the method in which the working-classes were housed in the metropolis, and the result is stated to have been so satisfactory that the number is now to be gradually increased up to 1500. It is also at last admitted that the method of dust removal in force is a failure. The "Lump Contract" system is an unwise one, for the contractor's main object, when he arranges for the work for a specific period, must be to make as much as he can out of the transaction. Until March, 1887, the present system must be retained; but it is expected that before that time arrives the Sanitary Committee, with the aid of the medical officer of health, will have a better scheme to submit; and it is suggested that the contracts about to come into force shall be placed under the supervision of the sanitary department, and that an experiment should be made with the movable pail system for some portion of the district containing about 500 houses. Re-arrangement of the inspectors of nuisances is to be made, so that each shall be responsible, amongst other things, for dust removal and inspection of registered houses in a definite area; and five additional officers are to be appointed. And, with a view of relieving the medical officer of health and the inspectors of nuisances from the more formal and clerical work of the office, a sanitary clerk is to be appointed to the health department, and is to keep and register complaints, have charge of the records of sub-let houses, attend to summonses under the Sanitary Acts, &c. The only point which remained to be dealt with was a structural alteration with a view of giving better access to the sanitary department, and this is postponed. The changes inaugurated are important, and we trust that they will be carried into effect with determination and energy.

ACROMEGALY.

UNDER the name of Acromegalie M. Marie described a curious affection characterised by an acquired hypertrophy of the upper and lower extremities, and of the head, the hands, feet, and head especially become enormously enlarged; the skeletons of the hand and foot are of gigantic proportions, and without appreciable deformity. In contrast the forearms, arms, and legs preserve their normal size, or only increase in size to a slight extent, as [illegible] described by Friedreich. The bones of the face [illegible] when the head is affected, and the general [illegible] countenance assumes that of an ellipse with [illegible] vertical diameter considerably elongated. [illegible] characteristic deformities, there exist other [illegible] ance curving of the spine forwards [illegible] volume of certain bones (clavicles, ribs, [illegible]

Digitized by Google

but not of the long bones, tendency to hypertrophy of the fibro-cartilages of the ear and larynx, slight deformity of joints, wasting of muscles, deafness and blindness, hypertrophy of the tongue, preservation of general sensibility, spontaneous pain, a tendency to varicose veins and hæmorrhoids, considerable thirst, abundant flow of urine, and absolute integrity of the skin with a certain condition of cachexia. The disease effects males and females between the ages of fifteen and thirty-five; but apart from the disappearance of the menses nothing is known of its etiology. M. Marie speculates on the nature of the affection, and inclines to regard it as due to a vice in the development of the osseous system analogous to the disease known as primary progressive myopathy. Clinically, the disease recalls myxœdema, osteitis deformans of Paget, and leontiasis ossea of Virchow.

THE WINTER OF 1885-86.

MR. CHARLES HARDING read a paper at a recent meeting of the Royal Meteorological Society which well deserves the attention of members of our profession, as supplying suggestive data for the study of weather in relation to disease. As a matter of fact, the winter of 1885-86, now happily drawing to a close though not quite ended, has not been productive of a high mortality or of prevalent disease, although it has occasioned very great suffering as well as distress. The large class of people who are afflicted with "nerves"—to use a popular expression—have been exceptionally strained and demoralised by the long persistence of "depressing" influences. There have also been many cases of rapid, and to some extent unexpected, death, occurring among persons who, while apparently in average or even more than average health, failed in force and tone with especial readiness when subjected to exhausting or inhibitory agencies. Thus, the number of deaths from pneumonia has been significant, if not really high. We are beginning to recognise that this malady is not a sthenic inflammation. It has a close relation to those states of the organism, however induced, in which the quantity of oxygen available for metabolic purposes is small; and probably to other states which are either the immediate results of blood-poisoning or render the organism peculiarly susceptible to what may perhaps be loosely called mephitic influences. In short, the pneumonia of recent days differs essentially from that for which our fathers and grandfathers were freely bled and purged, and is more closely connected with sewer gas and other forms of poisoning than with those reactionary inflammatory processes which are commonly regarded, or more accurately speaking used to be regarded, as the effects of chill. The congestion set up is what was once called "passive" rather than "active," and, instead of consolidation with effused lymph, there is loading of the organic structures with an exudation in which cells preponderate and fibrination does not speedily occur. All forms of disease have, during the recent winter, tended to what may be characterised as a low and rapidly exhausting type, with depressed nerve forces and vaso-motor disturbances of extreme degrees and wide variations. Mr. Harding's paper throws light on some of the atmospheric causes which have been at work, playing an important part in the production of the phenomena which practitioners in medicine, at least in populous districts, can scarcely fail to have observed. It seems that the *earth* has been colder than usual as compared with the air, being only some two degrees above the temperature of the atmosphere. This is a most important matter from a health point of view, particularly as regards the classes of persons who are susceptible to slight changes of temperature. The earth's temperature would seem to play the part of a stable point or centre around which fluctuations may take place harmlessly. Speaking generally, the winter has been excessively long, and the durations of spells of cold have been remarkable. Our readers will do well to study the paper in detail; but the relation of the earth's temperature to the atmospheric temperature is the point to which we desire to direct particular attention. From March 1st to the 17th, as Mr. Harding tells us, the earth was colder than usual by amounts varying from 6·3° to 8·5°; and, which is the important fact, it approximated more closely than usual to the temperature of the air around. Electric and magnetic conditions, undoubtedly affecting the nerve state in a marked degree, must have been greatly modified by this bringing together of what may be compared to the centre of gravity and the meta-centre in relation to meteorological equilibrium.

THE COLONIAL EXHIBITION HOSPITAL FUND.

THE first of the "Mechanical Beggars," invented by Dr. James H. Aveling, has been placed, as suggested by him, in the Colonial Exhibition, and is now busily begging for the London hospitals. It has been inspected by Her Majesty the Queen, their Royal Highnesses the Prince and Princess of Wales, the Duke and Duchess of Connaught, the Duchess of Albany, and the Princess Beatrice, who expressed themselves much pleased with its mechanism, and tested its working by depositing coins in the donation-box. It is to be hoped all visitors will follow the good example thus set; for if everyone who enters the Exhibition were to give but a penny, the amount realised would be about £10,000. The Exhibition "Mechanical Beggar" has two windows, through one of which may be seen a card in constant motion with "Pray give" on it; and through the other, but only when a coin is deposited, a card with "Thank you" on it, which jumps up and remains in sight a few seconds. The donations are collected by the cashier of the Royal Commission, and it has been proposed to hand over the sum realised to the Committee of the Hospital Sunday Fund for distribution.

SMALL-POX HOSPITAL ACCOMMODATION.

LAST week Mr. Stansfeld received, at the offices of the Local Government Board, a deputation which urged that there was no necessity for the proposed hospital at Darenth. Mr. Sly, the chairman of a conference of metropolitan boards of guardians which had been held upon this subject, acted as principal spokesman, and pointed out that the past experience of similar institutions had not been sufficiently satisfactory to warrant the expenditure of a further sum of £118,000 upon that at Darenth, while another guardian thought that a better site could be obtained on the waste land near the small-pox ships. The action of the Metropolitan Asylums Board in denying any responsibility for the effects of these institutions has raised a hostile feeling in the minds of many metropolitan local authorities, and has taught London to think of these institutions in any sense but that of preventers of disease in a community, and to this feeling is no doubt to be attributed the opposition of the present time. The Asylums Board have attempted to meet the difficulty of dissemination of small-pox from the aggregation of persons suffering from this disease only by removing the sick to a distance from London, and although this must minimise the evils which result from hospital treatment of small-pox, the managers are practically only postponing the evil day, which must come sooner or later as London grows. The means they have provided for the removal of the sick are so admirably designed that this is accomplished with much less fatigue and inconvenience than formerly, when the distance was less. The fact, however, remains that during epidemic times some aggregation of very severe cases must take place within

Digitized by Google

the Metropolitan area, and Mr. W. H. Power has clearly shown that the housing of only nine such persons is sufficient to give rise to an outbreak of disease in the neighbourhood of the institution in which they are placed. The difficult problem of hospital provision for small-pox is not yet solved, nor is it being solved; while therefore we may admire the public spirit of the managers in endeavouring to make provision for small-pox patients before the appearance of the next epidemic, we would gladly see some portion of the funds at their disposal devoted to the construction of an institution which should not be liable to the same accusations as were made with so much reason against the hospitals at Fulham, Hampstead, and Homerton. London is accustomed to regard the isolation of cases of small-pox as an important means of safety to individual households, and it should surely be possible for this to be effected without recurrence of the misfortunes which have attended all former efforts.

STATUE OF THE LATE ERASMUS WILSON.

THE simple but impressive ceremony of Tuesday last in the grounds of the Royal Sea-bathing Infirmary, Margate, went off to the evident satisfaction of all concerned. As soon as the occupants of the special train from London had arrived on the scene, Sir James Paget stepped, uncovered, on to the platform and opened the proceedings in the simplest possible manner. In a few admirably chosen sentences, every one of which told with his audience, Sir James depicted the remarkable career of Sir Erasmus Wilson, pointing out the growth of his riches, the success of his practice in dermatology, and his great love for medical science especially. The benevolence which Sir Erasmus loved to exercise was not bestowed in a general manner, but was guided by discretion and applied to objects in which the benefactor took a personal interest. Late in life Sir Erasmus became what was rare—an ardent and successful student of Egyptology; and the obelisk on the Thames Embankment would remain a permanent monument of this study. Mr. Russell Lowell, in the capacity of Vice-President of the Egyptian Exploration Fund, also testified to the love that Sir Erasmus Wilson bore to the study of Egyptology, and for two years he had defrayed the expenses of this fund. The bronze statue was unveiled by Sir James Paget, and revealed a most artistic piece of work, executed by Mr. Brock, A.R.A. After the unveiling of the statue, the visitors were invited to inspect the buildings of the infirmary, where they had an opportunity of witnessing the valuable additions made to the ancient building by the munificence of Sir Erasmus Wilson.

PHOTOGRAPHING THE RETINA OF THE LIVING HUMAN EYE.

A PAPER with this heading appears in the *Photographic News* of May 7th, by Mr. W. T. Jackman, of Coggleshall, Essex, and Mr. J. D. Webster, and the authors of that paper have been kind enough to forward to us specimens of the photographs they have obtained. The difficulties of making a good photograph of the fundus are extreme, and we can only congratulate these gentlemen on the results of their labours, though it must be admitted that, as yet, it only appears to be possible to obtain a picture of the optic disc and of the retinal vessels as they cross the disc. The first experiments of Messrs. Jackman and Webster were made by placing a small camera fitted with a 2 in. lens in the place of the observer's eye behind an ordinary ophthalmoscopic mirror, but subsequently various modifications were introduced which are fully detailed in the paper referred to. The best light was found to be an albo-carbon gaslight, having a reflector behind it and a bull's-eye lens in front. It was well borne by the eye. The reflection from the surface of the cornea was long found to be very embarrassing, but it was overcome with the exercise of a little ingenuity. In the photograph we have received, the physiological cup in the centre of the disc is very perceptible with the marginal portion of the disc, and the main blood-vessels and their primary divisions are distinctly marked. The result is sufficiently encouraging to lead us to recommend the authors of the paper to persevere in their efforts, and not to be discouraged by failure. Much greater difficulties than those which are here presented have been overcome by patience and the intelligent application of existing knowledge, and we expect soon to receive a still more satisfactory representation of the fundus of the eye.

HOSPITAL SATURDAY IN BIRMINGHAM.

SATURDAY, the 22nd inst., was the day appointed for paying in this year's contributions from the workpeople of Birmingham towards the support of its medical charities. The movement has been a brilliant financial success from the date of its initiation in the midland metropolis in 1873; and it is specially worthy of note that, trade depression notwithstanding, the annual total steadily grows. The Birmingham Joint Stock Bank, where the collection is always paid in, opened its doors for the special purpose at three o'clock last Saturday afternoon, and the staff remained cheerfully at work until nine o'clock. The *Birmingham Daily Post* reports that "at four o'clock 262 contributors were credited with £2944; at five, 360 with £3566; at six, 442 with £3980; at seven, 543 with £4386; at eight, 647 with £4818; at nine, 774 with £5332 19*s.* 6*d.* Last year the amount received at nine o'clock was £5094, and the number of contributors 809, so that the average contribution was £6 17*s.* 9½*d.* this year, against £6 5*s.* 11*d.* in 1885. These averages, however, are necessarily reduced by subsequent payments, inasmuch as all the larger contributions have been received. If, however, the subsequent payments raise the total at the same rate as they did last year, the workshop collection will reach £6712, as against £6446." The firms whose *employés* are at the head of this year's list with amounts over £100 are: G. Kynoch & Co. (Lim.), £371 16*s.* 8*d.*; Nettlefolds (Lim.), £139 8*s.* 9*d.*; Tangyes (Lim.), £102 8*s.* 1*d.*

BURIAL REFORM.

BURIAL, it seems to us, holds indisputably the first place among the various methods which have been adopted for the disposal of the dead. Not only does it present the various advantages which have been claimed for other systems, including that of cremation, but it meets the objections which have been urged against these on religious, social, and judicial grounds. In speaking thus, however, we must not be taken to deny the need of reform in our present customs of interment. On the contrary, we acknowledge traditional errors in this respect, and speak rather of what burial should and must become than of what it commonly is. That process which is exemplified throughout the generations of nature must be our model in this purely physical matter. We are made out of the earth, and we but follow the law of all created forms when our bodies are finally restored to the earth. But if we maintain this rule, we must uphold it in its simplicity. The stout case in which we are wont to enclose the dead, and fruitlessly to forbid decay, must be abandoned. To retain its use is a blot upon our civilisation. We corrupt Nature while we profess to copy her, and we store up for ourselves under our very feet the accumulated and postponed decay of many years. The more perishable the covering, the better for our purpose and the better for the health of the community. It may

Digitized by Google

be thought that further argument on this subject is hardly necessary, but we cannot forbear from expressing thus shortly our own opinion in support of the work which is being carried out on the same lines by the Church of England Funeral Reform Association. At a meeting of this Society at Grosvenor House on the 22nd, the Bishop of London spoke in favour of the adoption of measures for promoting "a fuller appreciation of the idea of Christian burial." Mr. Seymour Haden followed with a speech in which he showed that simple interment, such as we have above described, was not only by far the most suitable on economic and sanitary grounds, but was the form most strictly in accord with the familiar words which are daily heard committing "earth to earth." The resolutions proposed by both speakers in these terms were unanimously carried, as was also that in which both they and the Duke of Westminster agreed in recommending to all classes, especially to the wealthy, the duty of asserting by example the need of this salutary reform in our mode of burial. It is by organisation of this kind that public opinion can best be influenced on this important subject, and we may therefore expect that in time the present cumbrous practice will be replaced by others newer and better.

STRENGTH OF WILL.

To the logician and the practical thinker no subject is of deeper interest than the power of the will, as exemplified in the control of the passions by the higher mental faculties. Theoretically, everyone admits that the will is a great power; but not all are agreed as to the degree of its supremacy, and its capacity for development by careful culture and persevering exercise. Memorable historical incidents attest the difference which men and women exhibit in their power of controlling the emotions when called upon to witness or to endure suffering. When Moreau, seated on his charger at the battle of Dresden (Aug. 27th, 1813), beside the Emperor Alexander, had both his lower limbs shattered by a cannon-ball from the French lines, he was carried to the rear without uttering a groan, and placed upon a table in a cottage to undergo amputation of the right leg. He asked for a cigar and smoked it leisurely while the surgeon did his work. In a short time the latter expressed fears that the left limb was also so much damaged that it was very questionable if it could be saved. "Then cut that off too," exclaimed the heroic General, and he remained immovable throughout. How different the temperament of the great Sir Robert Peel. When carried home after a fall from his horse on June 29th, 1850, he was so exquisitely sensitive that he could not bear Sir Benjamin Brodie and the other attendants to touch him. It was found impossible to reduce his fractured clavicle. After death another fracture was discovered of the fifth rib, pressing on the lung; but the case was really one of a man of grand intellect utterly unable to subdue his emotions when suffering from pain. It is a popular idea that, in spite of their more sensitive nature, women can exercise more self-control and bear pain better than men do, and some extraordinary cases may be adduced in support of that belief. Dr. Paul F. Eve, in his "Collection of Remarkable Cases in Surgery," reports this instance of Cæsarean section successfully performed by a negress upon herself in the year 1769: "Being in labour, she seized a butcher's broken knife, about two inches and a half long, and cut through her abdominal wall on the left side near the middle line. The right thigh of the child presented, and it came into the world by the action of its own struggling. A negro midwife was sent for, who cut the umbilical cord and returned the part adhering to the placenta, and a considerable portion of the intestine also, into the abdomen, as it had come out of the wound with the child. The surgeon who attended the plantation was sent for a few hours after the accident; and judging, from the situation in which he found the patient, that some dirt had been put into the wound by the old midwife with the intestines, he cut open the stitches that had been made and carefully washed the parts clean, extracted the placenta at the wound, and then stitched it up again. The child lived five days. The woman recovered perfectly, menstruated regularly, and became pregnant again." Terrible as that occurrence was, how much more extraordinary was the fortitude of the Roman woman whose case was fully related in our columns last week. The facts would be incredible but for the signed attestation of Drs. Baliva and Serpieri, who were called to the patient thirteen hours after the first incision, and six hours after the small intestines had projected through the wound. Let the reader picture to himself the fact of the poor woman, oppressed with shame, three hours after midnight, long before the sun had risen—for it was March 28th,—alone in a peasant home on the slope of the Apennines, just thirty-nine miles from Rome, determining that she would give the lie to scandal, seizing the kitchen knife, thrusting it into her womb, wounding the child as she tore it out, binding herself up, walking into Viterbo to breakfast with her sister, and again homeward, only then fainting as the intestines gushed through the wound. The tragic picture has its ennobling side as a practical lesson of strength of will.

THE PROTECTION OF WEIRS.

WHEN an accident is evidently due to neglect of ordinary care on the part of those who suffer by it, we may refrain from censure where the debt of hardihood has been so dearly paid; but we cannot recall such events, nor can we by any mere contrivance prevent their occurrence. The accident at Bray, by which a boat was swamped in the weir and several lives lost, does not, however, seem to have been of this kind. An eye-witness writes that it was blowing hard at the time, and that steering was very difficult, while the disaster was clearly in no way due to want of skilful management on the part of the occupants of the boat. The mishap, moreover, is not a solitary one; similar fatalities have happened before in the same circumstances. It is to be hoped, therefore, that the lesson thus rudely taught will not be allowed to pass without finding its practical application, and that the Thames Conservators will recognise the duty and advantage of protecting weirs in some such manner as has been suggested, so as to limit the risks of boating on the river to those dangers which can with care be avoided.

CHOLERA IN ITALY.

IT is by no means easy to explain the state of affairs as regards cholera in Italy. Up to the 19th inst. there was a daily record of cases and deaths from the province of Brindisi, and up to the 20th inst. official information was regularly given as to the daily fatality of the disease both in Bari and in Venice. But from that date all news has ceased. It is hardly possible that the prevalence of cholera, which had been for some time maintained, and which had caused a substantial number of deaths every day for some time past, should have suddenly ceased, and this simultaneously, at both extremes of the Italian peninsula; and we feel bound to assume that, for purposes which we do not pretend to explain, the information as to the real state of affairs is being suppressed. It is, of course, possible that there has been a diminution in the extent of the outbreaks, and that it is thought best not to provoke the imposition of further quarantine measures now that these have become unnecessary. But, on the other hand, it must be remembered that, in view of the advance of the season when certain

Digitized by Google

parts of Italy are largely invaded by visitors, there would also be a strong inducement to hush up any extension of the epidemic. In the absence of all official returns, time alone can make clear the reasons for a suppression of information which must almost certainly have taken place.

SUICIDE OF A LUNATIC WHILE UNDER LEGAL CONTROL.

WE are not inclined to criticise the dealings of relieving officers with actual or alleged lunatics too severely, because we thoroughly appreciate their difficulties; but it ought to be a rule of practice, from which no departure should be allowed, that whenever and wherever a person is brought under the notice of a relieving officer as "a person of unsound mind not under proper control," or under any similar definition, such officer should take measures for his protection, as though he were both suicidal and homicidal, until he is finally discharged from his custody. A recent case, at Eastbourne, of suicide under conditions such as these is peculiarly distressing. There is only a minimum of blame to be attached to the officials concerned, because in this instance so much doubt existed as to the insanity of the person who ultimately committed suicide that two medical practitioners had actually certified that the alleged lunatic was of sound mind. Nevertheless, the fact remains that, due protection not being afforded, the poor man cut his throat while under legal control. The occurrence is a deeply regrettable one, and the rule of which we have spoken ought most certainly to be made; but we do not think there is any need of grave censure in this case as matters now stand, or as the duty of relieving officers is at present understood.

A LIBEL ON A SURGEON IN NEW ZEALAND.

THE *Lyttelton Times* of New Zealand contains a very full report of the trial of an action for libel brought by one of the surgeons of the Christchurch Hospital against the proprietors of the Wellington *Evening Press*. The libel complained of was contained in a highly coloured article, headed "Extraordinary Hospital Scandal; Revolting Disclosures; Manslaughter or Worse, ..." in which it was stated that at the Christchurch Hospital a man had recently been submitted to an operation for the radical cure of hernia, and had died owing to the "incompetence and criminal negligence" of the surgeon; and it went on to make many other painful statements. The whole story is a long and, we may add, exceedingly painful one, for it exhibits the profession in this colony in a very unpleasant light. It seems that a patient was admitted to the hospital for the express purpose of having this operation performed, that the operation was a difficult one, and that the man died in a few days with symptoms, in our opinion, of peritonitis. A most imperfect necropsy was made, and an inaccurate certificate of death was given. A colleague of the surgeon in charge of the case thereupon lodged a complaint with the hospital board and an inquiry was held, the result of which was that the surgeon was exonerated. Thereupon his colleague wrote to the Colonial Secretary, who very wisely refused to authorise a Government inquiry into the case. This same gentleman then had an interview with the writer of the article in question, who, as a result of the interview, wrote the alleged libel. We cannot refer to many minor points and side issues that were brought into the case. They do not materially affect it. We greatly regret such an occurrence, which can only tend to degrade the profession, and therefore injure the public. The operation appears to have been fully warranted and to have been properly carried out, although the result was fatal. As it was the first time such an operation had been performed at the hospital, or even in the colony, it would have been better to have had a consultation of the surgeons on the staff previously, and to have obtained their sanction and co-operation before proceeding further. Afterwards, a complete necropsy should have been made, and the cause of death carefully verified. But we fail to see how these errors justify the course that was taken by the colleague. A hospital can only be worked successfully when the staff are colleagues in more than name, and are ready to help each other in every way, and to share the responsibility of the position, which must at times press heavily. It was an extreme measure to bring this case before the hospital board; it was a grave mistake to make it the burden of a complaint to the Colonial Secretary; and when these authorities failed to interfere, it was altogether wrong to allow such charges as those we have quoted to get into the public press. Had we the space and the inclination to go into the case in all its details, we could easily point out flaws in the conduct of all the prominent actors in it. The verdict of a majority of the jury was in favour of the plaintiff, with one shilling damages, and with this finding we are inclined to agree.

THE BRECHIN ALMSHOUSE AND MEDICAL ATTENDANCE.

WE regret to see that Sheriff Currie Thomson has reversed the decision of Sheriff Robertson, which recognised the claim of Dr. Lawrence to be paid for his medical services to Miss Jamieson whom he attended in the Brechin Almshouse as a pauper, but who was afterwards found to be a lady of some property, and to be quite unfit to receive parochial medical attendance. The Sheriff Principal considers there was no contract between the deceased and Dr. Lawrence, only between the deceased and the parochial board, which included medical attendance on pauper terms, and expresses an opinion that a claim might lie against the board, who were paid by the deceased for, *inter alia*, the services of Dr. Lawrence, but who clearly had no right to be asked to attend a lady of property as if she were a pauper. We hope Dr. Lawrence will get a verdict against the board that will make them more careful in protecting the services of their medical men from abuse.

INFECTION AND REGISTRATION.

THERE is a good deal of force in the suggestion that means should be taken to prevent the transference of contagion in registration offices from those who have lately waited on deceased persons. It is among the poor, for obvious reasons, that infectious disease is most virulent and most fatal, whilst measures of cleanliness and isolation are alike difficult to apply. For the purpose of registering death, moreover, it is the rule that a relative present at the death, or someone who has been in attendance during the last illness, should be the bearer of the medical certificate. Under these circumstances, in addition to the fact that the registrar's office is not usually a spacious one, while the time of attendance is very limited, there can be no doubt that persons who have come thither from uninfected homes, notably those who attend to register births and may themselves be in poor health, may readily contract a dangerous or fatal illness. In considering how best to meet a difficulty of this kind, it is often more easy to propose a remedy than to apply it. Arrangements have to be made with regard to other business, and premises which are shown to be unsuitable may not admit of instant alteration. Fresh air and disinfecting substances are fortunately always at hand, and it would be well if registrars would frequently avail themselves of these useful agents. On the same principle, we may recommend to the notice of this department the manifest advantage of [illegible]

Digitized by Google

offices, wherever available, rooms of good size and capable of easy ventilation; nor does it seem a difficult matter to arrange that the time fixed for birth registration should precede or be separated by some interval from that allotted to recording death certificates.

PORRO'S OPERATION AND SIMPLE CÆSAREAN SECTION.

UNDER this title, in the *Journal de Médecine et de Chirurgie* for the current month, Dr. Just Lucas Championnière has summarised a report which he recently addressed to the Paris Society of Surgery. It is a noteworthy fact that for more than one hundred years no recovery has followed the performance of the ordinary Cæsarean operation in Paris, whereas M. Championnière has saved two out of four mothers on whom he performed Porro's operation, all the children surviving. These results and Dr. Godson's statistics notwithstanding, it is difficult to form an exact estimate of the value of the two operations. In country practices the simple Cæsarean procedure is not unfrequently successful, even when performed with comparatively little care; and it becomes a question whether those successes might not be made to exceed the results of Porro's operation, by utilising the advances of surgical therapeutics. M. Championnière had felt inclined to prefer the simple Cæsarean operation; but later and fuller experience has in his judgment weighed in favour of Porro's procedure, especially so in the hands of surgeons experienced in abdominal operations, and who have all surgical resources at command. He advises the simple Cæsarean operation in cases of fibrous tumours of the uterus, because they frequently render removal of the organ an impossibility.

PHARMACOLOGY AND THERAPEUTICS.

A CORRESPONDENT writes:—"The present position of pharmacology and therapeutics is undoubtedly unsatisfactory. It is difficult to over-estimate the importance to the community of investigations into the physiological action of remedies, and yet so much opposition is displayed towards workers in this particular branch of science that few care to engage in it. As a matter of fact, English pharmacologists constitute a very small body, and their number is becoming daily more and more limited. In Germany, and on the Continent generally, the subject attracts the greatest attention and its importance is fully recognised. The expense of a research is no light matter, and if the publication of a paper, however able, subjects its author to contumely and reproach, it is hardly to be wondered at if the younger members of our profession turn their attention to more lucrative fields of investigation. What is wanted is some kind of official recognition, and until this is forthcoming we must be content to obtain our information on the action of remedies second-hand from other nations, who are not so backward in recognising originality and talent and in adequately rewarding it."

TYPHOID MORTALITY IN MUNICH.

IN a lecture recently delivered by Dr. von Ziemssen on the mortality from typhus abdominalis in Munich, he exhibited diagrams showing the immense improvement that has taken place since the city has been supplied with a good system of drainage and sewerage, and since the establishment of various other important hygienic reforms. The average annual mortality in the hospital from typhoid from 1865 to 1880 was seventy-one, while that of the last five years was only ten. From these hospital statistics a calculation was made that during the last five years the number of persons in the city annually attacked by typhoid has been 1830 less than it was in former years, the number of deaths from the same cause being annually 213 less. The learned lecturer proceeded then to estimate the saving effected to the public, reckoning the average loss caused by an attack of typhoid as fifty days' labour at half a crown a day. He thus obtained the considerable sum of £11,437 as saved in the five years; and was therefore able to point out that citizens who had made great sacrifices for the improvements had already received great benefits thereby, not only in the way he had mentioned, but in many others besides, and he went on to insist on the necessity for the adoption of still further and more perfect sanitary measures.

THE INFANT KING OF SPAIN.

ACCORDING to *La Lanceta*, Dr. Sanchez Ocana, the physician to whom is entrusted the honourable and responsible duty of attending the infant King of Spain, has interviewed no less than twenty-seven women for the purpose of choosing a wet-nurse for his youthful Majesty. It seems to have been decided before the birth took place that the Royal mother was not to be allowed the natural privilege which is properly so prized by most mothers of lower degree—would that we could say so of all! But where Royalty sets the fashion, what wonder is it that others, with no public or extra domestic duties whatever to attend to, and so entirely without excuse, hasten to depute the mother's duty to a stranger.

PSYCHIATRY IN SPANISH UNIVERSITIES.

IN *La Independencia Médica* an earnest appeal is made to the Government by Dr. Valentí y Vivó, Professor of Forensic Medicine in Barcelona, to found chairs of Psychiatry or Mental Pathology in the Spanish universities. At present, he says, the only instruction the students receive on the subject of mental diseases is that which is contained in the lectures on therapeutics, pathology, hygiene, and forensic medicine; but a great deal more than this is required, and he hopes that a ministry which has already shown itself disposed to further matters connected with public health will not refuse to consider the importance to the State of having a body of physicians well trained in the science of mental pathology.

"BAUNSHEIDISM"

"BAUNSHEIDISM" is common enough in Eastern Europe, though fortunately but little known here. This consists in making a number of punctures with needle-points by means of a perforated plate and a corresponding instrument set with points, a strongly irritant oleaginous liniment of secret composition being subsequently rubbed into the skin over the punctures. This mode of treatment is sometimes beneficial in cases of chronic muscular pain of rheumatic origin; but when ignorantly used for any and every kind of pain, as it sometimes is, a good deal of harm frequently results. Thus, a Warsaw surgeon has lately reported two cases in which gangrene of a serious nature resulted from this kind of treatment. In one case amputation had to be performed.

SCALDING OF LUNATICS.

CRUELTY to lunatics by the carelessness of attendants is a very common cause of complaint, for which far too frequently for justice, though perhaps not often enough for expediency, the superintendents of asylums are held responsible. It has been said by experienced administrators that it is easier to govern a colony of madmen than to keep attendants up to their work or "be even with them" in the matter of duplicity and the needless and cruel coercion of the poor mind-sick folk entrusted to their care. One of the common "accidents," as they are mischievously called, which

Digitized by Google

befall the inmates of asylums is to be scalded, so that they die, in the baths to which they are forcibly subjected. The neglect shown in this particular is altogether inexcusable, and it is most desirable that this should be recognised. Such injuries as the fracture of ribs and the breaking of arms and legs are usually the outcome of bad temper, but the scalding of patients is a fruit of idleness or inattention, for which not a particle of apology can fairly be offered. An irritable or ill-tempered attendant is an anomaly; a lazy or a thoughtless one is a monstrosity, which ought not to be allowed to exist.

THE JOHNSON TESTIMONIAL.

AT a meeting recently held at King's College it was decided that a testimonial of a personal nature should be presented to Dr. George Johnson in recognition of his services to the hospital, on the occasion of his resignation of the Professorship of Clinical Medicine at the College and of the office of Physician to the hospital. An influential committee was appointed, and a lengthy list of subscribers has already been received. Dr. Johnson has given instruction to many generations of students, and, without doubt, many of those who have profited by his counsel and teaching will be glad of an opportunity of showing their appreciation of him. The treasurer of the fund, to whom subscriptions should be sent, is Professor Robert Bentley, 38, Penywern-road, Earl's-court, S.W.

THE LEICESTER ANTI-VACCINATIONISTS.

THE opponents of vaccination at Leicester grow more hardy in their defiance of law. "Home rule," like small-pox, is contagious. It is, by the action of the Government, in the air. If good for Ireland, why not for Leicester? Why should Leicester pupil teachers be revaccinated when the public opinion in Leicester is against vaccination? The Education Department has displeased some of the wise people of Leicester by applying the law of the land against two such pupil teachers. It is refreshing to see that the Government still recognises its responsibility as a central authority for enforcing, not the law of Leicester, but the law of England. We have no doubt there are many sensible pupil teachers in Leicester to be found who will comply with the law.

THE NEW SYDENHAM SOCIETY.

THE members of the New Sydenham Society will receive in the first volume for the current year a valuable contribution to the literature of one of the most important subjects of the day. The volume in question, of which we have had an early copy, has been edited by Mr. Watson Cheyne, and consists of selected essays on various topics connected with micro-parasites. It includes typhoid fever, erysipelas, tuberculosis, leprosy, rabies, actinomycosis, and many others, bringing each subject up to the present level of our knowledge. It is illustrated by a series of lithographic plates. The volume forms a fitting sequel to Koch's Memoirs on the Infective Process, which were published by the Society some years ago. It will be welcomed by many readers.

KLEPTOMANIA.

A WELL-MARKED case of kleptomania turned up at one of the Glasgow police-courts a few weeks ago. It was shown that the accused person, (a lady of independent means) had stolen two silk handkerchiefs from a warehouse in the town. The defence offered was a plea of kleptomania, in support of which a specialist testified that he had attended the accused for puerperal fever—a disease which, it was now known, was occasionally followed by this particular form of mania as one of its sequelæ. The same patient two months ago had purloined an instrument belonging to him, had hidden it under a pillow, and then assisted him actively in the search for it. He had had two similar cases. The plea of mental aberration and non-responsibility was sustained, and the accused was found not guilty, as it was impossible to say that she had "wickedly and feloniously" stolen the articles mentioned.

UNVEILING OF THE STATUE OF JOHN HUNTER.

ON Saturday (this day) the statue of John Hunter, presented by the Queen, will be unveiled in the Oxford University Museum. A short address on the Character and Work of John Hunter, with special relation to the effect of his labours on surgery and medicine, will be delivered by Sir James Paget, Bart., D.C.L., in the lecture-room of the museum. The statue will then be unveiled in its place in the court, and presented to the University on behalf of Her Majesty by Her Royal Highness the Princess Christian. All members of the University in their academical dress, and persons introduced by them, will be admitted. Any graduate may be accompanied by one friend. The address will commence at 2.30 precisely, when the doors will be closed.

PATHOLOGY OF SCURVY.

SCURVY being unfortunately a somewhat common affection amongst certain classes in Russia, papers on the subject frequently appear in the medical press of that country. In a recent account by Dr. T. Stazevich in a Moscow journal of eighty-six cases he had the opportunity of studying last summer, some attempt is made at elucidating the pathology of the disease. The writer made a careful microscopical examination of the tissues, and found in all cases he had the opportunity of observing an extensive degeneration of all the organs, and especially of the voluntary muscular tissue, which scarcely contained any really normal fasciculi; the bloodvessels were not greatly altered. He does not consider the petechial rash as due to capillary extravasation, but looks upon the spots as local hæmorrhagic inflammations. In the blood a large number of stellate corpuscles were found. The conclusion come to is that the disease is a "form of septic poisoning."

STREET COLLECTION FOR HOSPITALS.

MR. GEORGE R. SIMS writes to the *Daily Telegraph* complaining that his coachman, driving a hansom cab in which he himself was, nearly came to grief on a recent Sunday in Oxford-street through the noise of a brass band heading a procession which was making a collection for neighbouring hospitals. The fright of the horse was completed by a lad approaching the horse with a long pole with a money box at the end of it and shaking the coppers. The horse bolted and soon fell on the greasy wooden pavement, fortunately without killing anyone. Apart from this accident, we cannot admire this mode of raising money for hospitals. The intention is kind. The method is noisy and disturbing altogether out of proportion to the results. The friendly societies should leave the streets to the Hospital Saturday Fund, and find some other way to raise money for institutions by which their members so largely benefit.

VACCINATION BY UNQUALIFIED ASSISTANTS.

A PRACTITIONER at Liverpool, has been summoned before Mr. Raffles at the instance of the Vaccination authorities in London for having given improper certificates of vaccination. The gentleman in question has two dispensaries, which are attended by an unqualified assistant. This assistant was ascertained to have vaccinated children, and represented himself as the practitioner who signed the certificates. He

Digitized by Google

(the latter) justified this by saying that the public vaccinator used to act similarly in regard to children that he, the practitioner (when unqualified), vaccinated, and that he believed every professional man in Liverpool did the same. We agree with Mr. Raffles in condemning this practice, both on moral grounds and on the ground that vaccination ought to be performed only by responsible and qualified medical men.

ALLEGED CURE OF HYDROPHOBIA BY SWEATING.

THE report from Odessa of a case of cure after the onset of what are said to have been unmistakable symptoms of hydrophobia in a boy lends some encouragement to Buisson's mode of treatment to which we have alluded (THE LANCET p. 655). The symptoms of the malady began seventeen days after the receipt of the bite from a dog authoritatively stated to be rabid. The boy, at once removed to the hospital, was placed in a warm bath, the temperature of which was rapidly raised to 42° Reaumur (125° F.). At this stage the boy became unconscious and continued so for one hour. He was taken from the bath, swathed in cloths, and placed in a room at a temperature of 68°. The same process was repeated in the evening and twice a day for the following three days, when the patient's appetite was fully restored. So far the boy has remained well.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of April, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained in every case, excepting that of the Chelsea Company, more organic matter than in the previous month's samples, although the proportion is not in excess of what is usual at this season of the year. The water drawn from the Lea and supplied by the New River and East London Companies contained less organic matter than any of the Thames waters. All the samples were clear and bright. The number of micro-organisms discovered in the filtered water was in every case considerably less than in the March samples.

SEVERAL inmates of some workmen's dwellings in Högmarsö, a village near Stockholm, having been attacked with rigors and convulsions followed by cough and severe gastric pain, causing extreme prostration, and the nature and cause of this outbreak being very obscure, the "provincial medical officer" has received instructions to institute an examination into the circumstances, and to furnish a report for the guidance of the authorities.

TELEGRAMS from New York announce the death of Dr, Dio Lewis, the well-known physician. He was born at Auburn in 1823, and was educated at Harvard Medical School. Dr. Lewis deprecated the use of drugs, and advocated the introduction of physical exercise as a part of public education. He was the author of several works on hygienic subjects.

A LEGACY of some £15,000 has been left to the Jena University to be applied in zoological research on the basis of Darwin's evolution theory. The testator is Herr Paul von Ritter, of Basle, who believes the teaching of Darwin to be the greatest sign of progress which the century has yet given.

AT a meeting of the American Surgical Association held in Washington on April 30th, 1886, Sir William Mac Cormac was elected an Honorary Fellow of the Society.

ODONTOLOGICAL institutes are to be added to all the Prussian University establishments. At present Berlin is the only one that has such an institute. The next to be arranged will be in Breslau.

CHOLERA is reported to be increasing in the South of Japan.

UNIVERSITY OF LONDON.

AN extraordinary meeting of Convocation was held on the 25th inst., Dr. F. J. Wood, Chairman of Convocation, presiding.

Mr. MAGNUS moved that the report of the special committee appointed on Dec. 8th, 1885, be received. He said that the report was not the expression of the views of any one member, but of the whole committee; and contended that it was based upon resolutions passed by Convocation long before the idea of a Teaching University was started. The scheme involved the affiliation of provincial colleges, which was a distinct gain, there being no reason why the university should be restricted to London.

Mr. MAGNUS then moved the following resolution:—"That Convocation approves of the admission of certain educational institutions having one, or more than one, faculty of university rank as constituent colleges of the University, and agrees with the proposals relating thereto contained in Section 4 of the subjoined scheme." (See THE LANCET, May 22nd, p. 994.) He cited the Vice-Chancellor's remark that in any change in the University it should seek to add to its useful functions, and not to take away from them. It had long been felt that the teaching institutions of London should be more closely united, and this would be effected by bringing them into connexion with the University. He warned those who desired to set up another university in London and who might oppose the present scheme, and believed that the majority of members of Convocation would affirm the value of the reform.

Mr. ANSTIE, Q.C., seconded the resolution.

Mr. T. TYLER objected that the scheme introduced a new department of the University, which hitherto consisted of fellows and graduates, and would now contain "constituent colleges" also. He also asked what was meant by colleges of "university rank."

Dr. MOXON was astonished not to see any of the supporters of Lord Justice Fry's scheme opposing the present one. But he did not think this reform would meet the views of those who advocated a Teaching University—i.e., an institution where the aptitude and training of a man could be estimated as well as his knowledge tested. He had however, no objection to the scheme so far as it went.

A MEMBER pointed out that the University of London was founded on broader ideas than that of a local teaching university. It was meant to be open to all comers; and he thought it should retain its universal character; but at the same time there was room in London for a great teaching local university.

Mr. HANHART objected that the sections of the scheme were not being discussed in due order, and moved as an amendment that the words "affiliation to the University" be substituted for "admission."

Mr. BROWN seconded the amendment.

Dr. CURNOW supported the resolution, but did not think it went so far as the Teaching University proposals or as Convocation had itself desired. It might be accepted as an instalment; but the next resolution was one which should be amended.

Messrs. LYNN and ELLIOTT supported the amendment.

Dr. SYLVANUS THOMPSON explained the reasons for taking the scheme in the order of the resolutions, and said that the word "admission" was used in a general sense.

Dr. SANSOM thought the tendency of admitting colleges would be to lower the value of degrees. There was room for another university in London, which should grant degrees equal to those of other existing universities, if not so high as

Digitized by Google

the University of London. He urged that nothing should be done to depreciate the degrees of the University.

Several other members spoke, one of them averring that it would not meet the views of the Teaching University, nor satisfy the requirements of University and King's Colleges.

Mr. MAGNUS, in reply, said that the proposal of the Colleges of Physicians and Surgeons to grant degrees was quite apart from this question.

The amendment was lost.

Another amendment, moved by Mr. TYLER and seconded by Mr. LYNN—viz., "That Convocation approves of the revision of the list of institutions in connexion with this University, with a view to such institutions being brought into closer relation with the University"—was negatived, and the original resolution put and carried by a very large majority.

Mr. MAGNUS then moved, "That Convocation approves of the establishment of a Council of Education as a part of the University, and of the proposals for giving effect thereto contained in Section 5 of the subjoined scheme."

This was seconded by Mr. ANSTIE, and after a brief discussion, interrupted by a motion to adjourn the House, was carried.

The House was proceeding with the next resolution—viz., "That Convocation approves of the proposals for the constitution of the Senate of the University contained in Section 2 of the proposed scheme,"—an amendment to introduce the Institute of Civil Engineers having been rejected, when the adjournment took place until June 29th, the day fixed for nominations to the Senatorial list.

THE GERMAN MEDICAL CONGRESS.

(*Concluded from page 948.*)

A DEBATE upon the "Treatment of Syphilis" was opened by Professor KAPOSI (Vienna), who said that it had not made equal advance with our knowledge of the pathology of the disease. Mercurial inunction—now, as four centuries ago—remained the most reliable treatment; and the only notable gain to treatment since the first half of the sixteenth century was the introduction of iodine in the middle of the present century, and, as regards the administration of mercury, the rational use of inunction and the subcutaneous injection of the drug. The *laisser aller* principles of the treatment of syphilis held by the Broussais school, and the erroneous doctrine which attributed late manifestations to mercurialism, were briefly combated. Syphilis must be regarded as a curable disease, one of the most curable of all the infective constitutional maladies, for we possess remedies and methods which act directly and powerfully upon the local lesions, as well as on the general blood disorder. It is much to be desired that the experience of practitioners should be periodically collated so as to establish a common understanding on the value of any special line of treatment. The first question raised was, *Does treatment of the initial forms prevent general infection?* This question may be discussed alike by those who hold the unitarian doctrine that every kind of primary lesion may be the starting-point of general infection, and by the dualists, who assign this part solely to the typical sclerosis. If, with von Bärensprung, the sclerosis (hard chancre) is regarded as a symptom of actual constitutional infection, then the question of abortive treatment falls to the ground; but if the probably truer view be held—viz., that the specific virus is limited for a time to the primary lesion, and is thence conveyed to the tissues by the lymphatics and blood-vessels,—then, theoretically, this absorption might be prevented and constitutional infection guarded against. The methods theoretically and practically possible to effect this object are threefold. In the first place, the virus may be destroyed at the seat of inoculation, as by cauterisation or excision of the primary sore. The non-development of syphilis following such treatment cannot be taken as positive evidence of its effectiveness, because every sclerosis is not necessarily followed by syphilis, and because the truly syphilitic nature of the primary lesion rests on the testimony of the surgeon who excises it. Nor is there any means of determining a period when the excision of the local lesion may be successful. Again, the presence or absence of glandular swelling does not suffice to determine the syphilitic nature of the lesion. If Lustgarten's bacilli could be trusted as a test for syphilis the nature of a primary sore might be determined. Practically, excision is easy enough when the sore is preputial; but it can be less thoroughly practised when this is seated on the glans or sulcus coronarius. In the second place, systemic infection may be prevented by interrupting or closing the path of absorption, which it has been professed to effect by division of the dorsal lymphatics, and, if desired, by excision of glands. This is a very naïve proposition, for injected preparations show that the whole penis lies embedded in a dense meshwork of lymphatics. In like manner the value of mercurial and iodic injections into the primary lesion to destroy the virus during absorption may be discarded. In the third place, there is the abortive treatment. Is it not reasonable to employ systemic treatment early in every case when the specific characters of the primary lesion are manifest? Although this may be rational and humane—for it is, theoretically, imprudent to suffer a disease to attain its full intensity before commencing to treat it,—yet, practically, it is not of much use. Experience teaches that the outbreak of general symptoms is not prevented by such early treatment, but only postponed; that the symptoms then follow a disorderly and atypical course; and that generally there appear, not merely mild exanthematic affections, but very early severe symptoms—e.g., periosteal. Therefore, in his experience, it is unnecessary and injurious, as well as perplexing, to the practitioner to attempt systemic treatment before the clear manifestation of constitutional symptoms. It is wiser to allow the disorder to develop, and to defer treatment until the first appearance of roseola. The second question raised was *the relative advantages of anti-syphilitic remedies with reference to the pathological phenomena.* The answer to this depends upon establishing a principle upon which to estimate the activity of a remedy or method of treatment, and to critically survey such methods. The activity of a drug is estimated by the promptitude with which its employment results in the disappearance of visible and palpable phenomena, and in the freedom from relapse. On the latter point, in which the cure of syphilis solely consists, judgment is difficult. Hospital patients are discharged as soon as external visible symptoms have disappeared and only a small proportion come again under treatment, and are available for statistics, which are therefore worthless. It is only in private practice that information as to the cure of syphilis can be gained, and here no statistics are available; Prof. Kaposi summed up his experience by saying that there are many patients who remain cured after a single course of a few weeks' or months' duration; but there are many who undergo one or several relapses before being cured; and, finally, that in a small number who have been free from symptoms for years, and have procreated healthy children, relapses of syphilis—cutaneous, cerebral, and other—may arise. It is quite impossible to fix a limit to the time over which a drug may be administered. The occurrence of relapses tells nothing either for or against the value of a drug; for relapses may occur under the most favourable conditions. It is desirable that after a sufficient treatment several months should be passed without any symptoms; and the disappearance of polyadenitis must be borne in mind. The remedies known to be most active are—(1) mercury, (2) iodine, and (3) vegetable decoctions[1] (*holz-tränke*); to which may be added the so-called after-cures, as sulphur and sea baths; and, lastly, Fournier's protracted plan. Mercury can be introduced into the body in many ways, the most important being inunction with grey mercurial ointment. As the absorption of the drug depends on the fat with which it is mixed, lanolin alone is useless as the basis of an unguent. Empl. hydrargyri is less efficacious except for the local treatment of gummatous infiltrations. Sublimate baths are of use in infantile syphilis, and in adults in cases of extensive ulcerating gummata. The introduction of the hypodermatic treatment by Lewin has been of great service; it is more exact and direct than any other mode of administration, and a large number of mercurial preparations may be administered by its means. These preparations vary in their efficacy as well as in their liability to produce local

[1] Sarsaparilla mainly.

Digitized by Google

lesions, and Prof. Kaposi concurred in the following scheme drawn by up Bockhart to classify the various preparations:—

1. Mercurial preparations of markedly durable action—
   (*a*) Inunction (Neapolitan ung. hydrag.).
   (*b*) Calomel injections. } Subcutaneous.
   (*c*) Lewin's sublimate solution. }
2. Mercurial preparations of moderately durable action—
   (*a*) Sublimate; chlornatrium. }
   (*b*) Albuminate and peptonate of mercury. } Subcutaneous.
   (*c*) Blood-serum—mercury. }
3. Mercurial preparations of slightly durable action—
   (*a*) Mercury bicyanate. }
   (*b*) „ glycocoll. } Subcutaneous.
   (*c*) „ formamide. }

The least painful of these is the formamide. Internally, sublimate, calomel, and tannate of mercury are useful, the last especially producing but little effect on the stomach; also protiodide and biniodide, which are more frequently prescribed in France. Professor Kaposi thinks that mercury should be given in all forms of cutaneous affection in the early period, and in the late period for diseases of bones, of parenchymatous organs, and of the cerebro-spinal system in acute stages; whilst iodine is preferable for joint affections and syphilitic cephalalgia of the later stages. The more resolute and prolonged the treatment of acute affections, the more certainly may relapses and a protracted course be avoided. He therefore advocates inunctions where possible, and failing them injections of the more durable agents, less active medication being reserved for those late forms which are not of urgent nature. The more serious affections—as iritis, ulcerations of the naso-laryngeal tract, and affections of the brain and spinal cord—must be treated actively by inunction. Mercurial treatment never gives rise to sequelæ so long as it is carefully given. Iodine is useful in bone and joint affections, especially for nocturnal pains, and also for the symptoms of the gummatous period. In the early stages iodine should never be prescribed alone for fear of protracting the disease, and it is a mistake to suppose that iodine corrects the abuse of mercury. The "decoctum Zittmani" is useful in late forms, especially of ulcerations of the throat and skin, and may be combined with inunctions. It is preferable to the "decoctum Pollini," which injures the appetite. The after-treatment by sulphur baths, hydropathy, &c., has no specific action. The third question dealt with by Professor Kaposi was *how long and how often should anti-syphilitic treatment continue?* In general, the first treatment should be carefully pursued for a long time, and then only repeated as often as the symptoms of syphilis recur; when there are no signs, treatment is superfluous. But a rational course of treatment can do no harm, and there is nothing to urge against its occasional repetition within the first year; but in deciding upon the need of this the practitioner must deal with the individual case. Besides the constitutional treatment, local measures are in many cases needful, such as ulcerations of the nose, pharynx, and larynx.—Dr. NEISSER, who followed, spoke of the numerous differences which still obtain among practitioners in the treatment of syphilis; but he would not abandon the hope that in the future, by means of careful and critical analysis, more certain principles would be established. The experience of single individuals needs to be corrected by the sum of the experience of many, and in this direction much might be done by collective investigation. With this object he directed attention to the following points: Is it possible to prevent the outbreak of syphilis by removing its primary effects? Ought the constitutional disease to be attacked with remedies, or should it be left alone? What plan can be established for a treatment which may be generally accepted? Each of these questions he discussed in turn. 1. That syphilis is a bacterial disease may be now generally accepted, the Lustgarten-Doutrelepont discovery being a distinct advance; but the important question of the time and manner of the dissemination of the microbe from the seat of infection cannot be determined by experiment, since syphilis is incommunicable to animals; it must be decided clinically. We are unable to base our treatment on pathological knowledge, but the results of treatment may help to solve the pathological problem. In most of the published cases excision of the primary lesion has had no result; some have remained healthy. Negative results are open to the objection that the operations were not radical enough or were deferred too late, and positive results may be ascribed to the fact that they were not cases of actual specific lesions. Further investigation is needed, for it may be taken that in a great number of cases the virus remains for a long time at the seat of infection, and therefore may be removed, especially if attacked early enough. Results may be uncertain, but no harm can come of excision, which is the best local treatment. If excision be not practised, then cauterisation by strong carbolic acid is to be recommended. 2. He agreed with Kaposi that, once constitutional syphilis is declared, the best remedies are mercury and iodine, without forgetting attention to hygiene, diet, &c. Mercury should be given as soon as the diagnosis of syphilis is established, for although the course of syphilis is not cut short its intensity will be diminished. Syphilis, if untreated, may pass on to recovery; but far more often it leads to destructive processes, as the history of endemics teach. There is no sure ground for prognosis or the estimation of the later course of the disease from its early stages. In every case left untreated the possibility of tertiary manifestations must be borne in mind. But the action of mercury being directly antidotal, it is obligatory to give it, although under slight necessity, on the chance of mitigating severe symptoms and to effect a cure. He agreed with Fournier's plan of commencing treatment as early as possible, often before the appearance of a rash. He did not think such early treatment harmful; but its value or inutility as a prophylactic must be regarded as an open question. 3. He also agrees with Fournier in prolonging treatment for three or four years, a chronic disease requiring to be treated chronically; and for this purpose the continuous administration of small doses may be intermitted with larger and more active ones. The choice of a drug is less important than the amount of mercury administered, and it is wrong to adhere to one remedy or one method. As a rule treatment should be active at first, and at any recurrence, the intervals being available for iodide of potassium or milder mercurials. The various methods of mercurial inunction may be successively combined, so as to bring as many lymphatic gland regions under its action as possible. Baths, "drink cures," "sweating cures," pilocarpine, and wood decoctions are only to be regarded as aids to specific treatment. Iodine holds an intermediate position, having in the later stage a specific action. It is indispensable, but is generally given in too small doses. Even children will bear very large doses. There is no essential difference between the iodides of potassium, sodium, and ammonium. It is questionable if iodoform given internally or subcutaneously is of any service.—Dr. WEBER (New York) spoke of the prevalent methods in America. A notable feature is the early administration of iodide of potassium, even at the beginning of the secondary stage; and of much larger doses in all stages than in Europe. Duhring and Keyes have shown that large doses are borne very well, taken in soda-water or milk. Mercury is generally given on the French plan—the protoiodide internally, and yields good results. The use of Zittman's decoction is little in favour; indeed, of late years a large number of vegetable fluid extracts (mostly derived from the Indians' armamentarium) have been introduced, but Dr. Weber was unable to report any favourable results.—Professor v. ZIEMSSEN (Munich) said they required observation and statistics of cases treated on one plan for comparison, and the deduction of the relative value of various methods. He was satisfied to prescribe the subcutaneous administration of bicyanate of mercury, and had seen good results follow the combined use of that preparation and of iodide of potassium in visceral and cerebro-spinal syphilis.—Dr. SCHUSTER (Aix) remarked on the excretion of mercury.—Dr. ZIEMSSEN (Wiesbaden) advocated the separation of patients from their families, and their treatment at health-resorts.—Drs. EDLEFSEN (Kiel) and LEUBE (Wurzburg) commence treatment as soon as the syphilitic nature of the chancre is established. Inunctions are more lasting, injections more rapid; and care should be taken in the administration of large doses of iodide of potassium.—Dr. BAUMLER (Frieburg) spoke on preventive treatment, and recommended early resort to mercury. Mercury is also indicated in the secondary stage, and iodide of potassium in the tertiary. It was important to look after the nutrition of the patient.—Dr. DOUTRELEPONT (Bonn) strongly advocated calomel injections.—Dr. SCHUMACHER protested against a prolonged intermittent treatment as unnecessarily weakening the patient.—Professor KAPOSI, in reply, said that no unanimity had been expressed, nor could it have been expected, on the therapeutic value of the various methods of administering mercury; and as to preventive treatment, he looked

Digitized by Google

forward to more information being gained by collective inquiry. He also humorously critised the prevalent plan of treating syphilis by subcutaneous injections as likely to eventuate in rendering it so curable that syphilis wards would no longer be required in hospitals.

Dr. KAHLER (Prague) read a paper on the Experimental Production of Permanent Polyuria. Cases of polyuria following injuries to the skull do not solve the question as to the precise locality of which lesions produce polyuria. Of twenty-two recorded cases, in six the middle parts of the brain were damaged, in four the pons, in two the medulla. Claude Bernard never succeeded in producing permanent polyuria; and his experiments were carefully repeated on rabbits with modifications, the animals being kept on dry food, and the urine strictly measured. By making a deeper puncture than Bernard, and injecting minute quantities of nitrate of silver, a marked and lasting polyuria was excited, although its degree varied spontaneously from time to time. Examination showed that the lesion in such cases involved the posterior part of the pons, and the medulla near the restiform body.

Dr. DEMME (Berne) described a case of Acute Pemphigus in a well-nourished country lad, thirteen years of age, who whilst under observation had seventeen acute attacks, generally accompanied by fever, vomiting, mild delirium, and depression. A characteristic diplococcus was found in the blood, urine, and fluid of the vesicles, in amount proportionate to the severity of the eruption. The vesicular fluid also contained some isolated larger cocci and occasionally bacilli containing spores. Inoculations of pure cultures of the diplococcus were made, with negative result, in pigeons, dogs, cats, and rabbits; but in the guinea-pig intra-pulmonary injections produced fatal pneumonia with great development of diplococci. It seemed probable that acute pemphigus was due to this micro-organism, which he could not detect in pemphigus foliaceus or in syphilitic pemphigus. The case was treated with antipyrin internally and the application of a hydrochinone (1 in 30) ointment, and it eventuated in recovery.

Dr. REHN (Frankfort) exhibited a well-developed girl, twelve years old, who during the first months of life had been twice tapped for simple chronic hydrocephalus.

Dr. RAHL (Vienna) related his experience of Syphilis Hereditaria Tarda, of which he had seen 112 cases. In no case had symptoms appeared before the second year. The most frequent were—bone disease in sixty-two, ozæna in forty-two, and eye disease in thirty-six. Three cases were of special interest, for, having been under medical observation since birth, it was proved that there were no syphilitic manifestations until the seventh, fifteenth, and sixteenth years respectively.

Dr. HEUBNER (Leipsic) read a paper on Scarlatinal Diphtheria, and its treatment by means of parenchymatous injections of a 3 per cent. solution of carbolic acid into the tonsils and arches of the palate with a specially devised instrument. He said that on this plan mortality had fallen from 35·6 per cent. to 13·8 per cent.

Dr. FRIEDLANDER (Leipsic) read a paper on the Typical Course of Articular Rheumatism. He distinguishes two types—one having a maximum duration of seven days, the other of thirteen days. Cases of longer duration were combinations of both types. The maximum temperature is attained on the third or fourth day; and in the course of one attack no joint is affected more than once.

Professor QUINCKE (Kiel) exhibited three distinct forms of Fungus from a single case of Favus, but had not been able to determine whether each variety was equally competent to excite the disease.

Dr. SCHUMACHER (Aix) spoke of Localised Hydrargyrosis and its Laryngoscopic Diagnosis. He averred that mercurialism produced changes in the buccal mucous membrane, resembling those due to syphilis; but, on examining the root of the tongue with the mirror, broad, sharply defined, and characteristic patches may mostly be detected.

Dr. LITTEN (Berlin) related a case of Pyopneumothorax, with Cercomonades in the Pulmonary Tissue. A patient was tapped for pleurisy, after which succussion, but no other sign of pneumothorax, appeared. On a second puncture, there appeared suddenly another sign, elicited on movement—viz., a bubbling râle; and the conclusion was that there was a pleural fistula with valved outlet. Microscopic examination of the exudation revealed cercomonades (monas lens), which were also found in the sputum. The presence of these animalcules has been thought to indicate pulmonary gangrene, but no symptom of gangrene occurred in this case. Tubercle bacilli were, however, once found, pointing to the cause of the pleural fistula.

Dr. FRANZ (Liebenstein) gave an account of cases of Chlorosis cured by the Oertel Method, where iron had been of no service.—Professor LEYDEN, however, warned against overstrain of the heart in chlorosis.—Dr. BREHMER had seen better results in cardiac cases from Schott's gymnastics than from the Oertel cure.

Dr. BLOEBAUM (Coblenz) advocated Galvano-cauterisation in the treatment of Diphtheria. He said it was painless, and was not only destructive of bacterial life but prevented absorption of ptomaines.

Dr. SCHULZE (Heidelberg) read a paper upon Syringomyelia, which was easy to diagnose, producing partial sensory paralysis, with spastic paralysis of the lower limbs. The sensory paralysis may consist of partial analgesia, as in a case where no pain was felt from a broken arm. In a case of cellulitis of the hand, which led to amputation and to fatal pyæmia, the supervention of spastic paralysis of the lower extremities led to a diagnosis of syringo-myelia, which was confirmed post mortem. The etiology of the condition is unknown.

Dr. E. PFEIFFER (Wiesbaden) reported upon the Etiology and Treatment of Uric Acid Calculi. He finds that chloride of sodium waters (as the Kochbrunnen in Wiesbaden) have very little solvent effect on urinary calculi, but that alkaline waters (as Carlsbad) have much more marked action. But in each case, on leaving off drinking the mineral waters calculi form again very rapidly. Lithia water—the artificial being twenty times stronger than the strongest natural—has very slight solvent properties. More powerful is the purely alkaline water of Fachingen, which he recommends should be taken continuously for a long period in cases of renal and vesical uric acid calculi.

At the conclusion of the four days' session, the President, Professor Leyden, thanked the members for their participation in the Congress, especially those who had come from distant countries, as America, Russia, Austria, Switzerland, Holland, and Belgium, and invited all to meet again at Wiesbaden next year.

BURGH POLICE AND HEALTH (SCOTLAND) BILL.

IN addition to the provisions, which we have already noticed, for the appointment of medical officers of health and for the adoption of measures to prevent the spread of infectious diseases, the Bill proposes to confer important powers upon the Commissioners in connexion with the erection of new buildings, the occupation of dwelling-houses, the construction of public sewers, the control of house drainage, and the supply of water. We shall notice a few of the more important of these.

Clause 168 forbids the erection "of any building upon any ground which shall have been filled up with any material impregnated with fæcal matter, or with any animal or vegetable or other offensive matter, which, in the opinion of the medical officer or sanitary inspector, may tend, by decomposition or otherwise, to the prejudice of the health of any future resident or occupier of such building, or of any resident in the neighbourhood, except upon a certificate of such medical officer or sanitary inspector that proper precautions have, in his opinion, been taken to obviate any such result." No new or altered building will in future be permitted to be occupied until it has been certified by the surveyor of the burgh to be fit for occupation and in accordance with the provisions of the Act. The Commissioners are to have power, "after cause shown," to order means of ventilation, approved by them, to be provided in every building, whether erected before or after the application of the Act; and where not already existing, to order, or if necessary to construct at the expense of the owner, such means of drainage as they may consider requisite. The surveyor of the Commissioners is to be authorised, when requested by the medical officer of health or the sanitary inspector, to open for the purpose of inspection any drain or cesspool; if it be found in good order, all the expenses incurred in the inspection to be defrayed by the Commissioners. Provision is made for the

Digitized by Google

compulsory introduction of water, at the expense of the owner, into every house or part of a house occupied by a separate family, and for fitting up a sink, duly trapped, and, wherever practicable, a sufficient watercloset; the sinks, soil-pipes, and waterclosets to be trapped and ventilated. Every watercloset, earthcloset, or privy must be placed so that one of its sides shall be an external wall, with a window in it of at least six superficial feet and one-half made to open; and the soil-pipes from waterclosets must be kept wholly disconnected from all other pipes except ventilating pipes. The Commissioners are to be empowered to take the necessary measures for obtaining or providing and maintaining, for the use of the borough, an adequate supply of pure and wholesome water, and to make bye-laws, *inter alia*, "for inspecting and periodical cleansing of cisterns erected in buildings for the use of two or more families."

In the building of new dwelling-houses it is proposed to enact that every habitable room on the ground floor shall have a height of at least 9 ft. 6 in. from floor to ceiling; on all other floors except the attics, of at least 9 ft.; and in every habitable attic the height shall be at least 8 ft. through not less than one-third of the area, and in no part less than 3 ft. Every habitable room must have at least one window, the area of the glass of which shall be at least one-tenth of the area of the room, the top of it not less than 7 ft. 6 in. above the floor, and one-half at least made to open. It is proposed also to regulate the occupation of houses by making it unlawful for any owner to let or any person to take on lease any building which, if consisting of one apartment, does not contain at least 700 cubic feet of space if it was used as a separate house before the passing of the Act, or 900 if not so used; if consisting of two apartments, it must contain 1200 or 1500 cubic feet; and if of three apartments, 1800 or 2000 cubic feet. Each apartment must have a window, and the cubic space is to be calculated free of all obstructions. We confess we are unable to see the reason for this distinction between a house "used as a separate house" before the passing of the Act and after it. If the larger space is requisite for the health or comfort of the inmates, it should be imperative in all cases; if not necessary, it is unjust to require it. We presume it is a concession to some supposed vested right, but no such right ought to be permitted if inconsistent with the public health. Rules are laid down for the regulation of common lodging houses with a view to promote health, cleanliness, and ventilation, and to prevent overcrowding. Every keeper of such house is bound under a penalty to report if any lodger has been confined to bed or affected for twenty-four hours with any infectious illness.

Such are some of the more important points bearing upon public health. The Bill will confer great powers upon the Commissioners, and necessarily also great responsibility. If these powers are exercised firmly and judiciously we cannot doubt that the Bill will have an important bearing upon the lives, the health, and the comfort of the inhabitants of the burghs to which it is applied. We trust that in committee it will be amended as regards the annual appointment of the medical officer of health, the verification of the diagnosis of qualified medical practitioners who report cases of infectious disease, and the distinction drawn between houses occupied as separate houses before and after the passing of the Act.

THE MALARIA PROBLEM IN ITS LATEST PHASE.

IN THE LANCET of the 10th ult., p. 708, we announced that Dr. Schiavuzzi had presented to the Roman Accademia dei Lincei some microscopic preparations made with cultures of a bacillus found by him in the malarious atmosphere of the regions around Pola in the Istrian Triangle. Now, according to Professor Tommasi-Crudeli, although the bacillus in question in Dr. Schiavuzzi's preparations assumes forms identical with those of the bacillus malariæ, it is by no means certain that the two bacilli are one and the same micro-organism. The configuration alone is not sufficient to characterise the bacilli of the various infections, it being well known that the comma bacillus of Koch, believed at first to be the unvarying principle of cholera, is found identical in patients and localities where no shadow of cholera exists. Micro-organisms, quite undistinguishable as to form, may be malignant or innocuous, so that recourse must be had to experimental proof from cultures made *ad hoc* to determine whether the bacilli can cause specific infections or not.

Another question yet awaiting solution is that of the nature of the alterations wrought by the malaric infection on the blood-globules. Our readers are familiar with the results of Laveran's researches, as well as of those of Drs. Marchiafava and Celli on this subject. By the malaric infection the colouring matter of these globules turns from red to black, being converted into a substance called melanine, while the interior of the globules is at the same time invaded by a substance called hyaline. Laveran attributed these alterations to a living organism which penetrates the globules; while Marchiafava and Celli, to whom belongs the merit of having first thrown light on the alterations in question, observed that the hyaline substance possesses a certain motility, and inferred that it was a parasite to which the destruction of the blood-globules is due; and as after the globule is destroyed the hyaline substance divides into a granular débris, they ascribed to these granules the reproduction of the parasite. Similar conclusions were reached by Golgi, who supported the parasite theory by the observation that in the globules, before their transformation into granular débris, there is visible a fragmentation (*fragmentazione*) which divides the globule itself into fine segments. Now, Professor Tommasi-Crudeli holds that the phenomena described by Marchiafava, Celli, and Golgi have not been justly interpreted by these observers. Already, in 1884, at the Copenhagen Congress, he explained the alteration of the red globules as a degeneration of their protoplasm determined by a morbigenous agent, and not a development of an animal parasite. Indeed, the movements encountered in the hyaline substance which invades the globules, and advanced as proof of the presence of the parasite, have little value, if only for the reason that in many blood diseases, and as the result of a heightened temperature, the protoplasm undergoes alteration and acquires a more or less marked motility. So also the degenerations described by Golgi as a fragmentation, by which the parasites are reproduced, are encountered in analogous degenerations caused by violent agencies, as by an electric discharge, or by treating the globules with certain saline solutions. On the other hand, no one has ever seen the granulations in process of conversion, step by step, into the parasite, nor can any trace of this last be found in the air or in the soil of the malarious localities.

But there are yet other considerations. What we in these days know of the progressive infection of organisms excludes the notion that it depends on an animal parasite. On the other hand, we have numerous examples of infections produced by vegetable parasites. The malaric infection presents such a variety of forms, from the slightest to the most acute, and there are such intervals of time between its attacks, as no animal organism hitherto known could be capable of producing. Moreover, the improbability of the animal nature of the parasite is proved by the property inherent in the malaric ferment of remaining buried for centuries without losing any of its pernicious qualities, so that (and Rome supplies examples every day) one excavation or disturbance of inert soil to a certain depth suffices to liberate the ferment and to make a locality, till then innocuous, the scene of a febrile explosion. We know that the seeds of plants can preserve intact their peculiar germinative power, even after being buried for centuries, like the grain found in the coffins of Egyptian mummies. So, also, the cutting of a tract of soil in a deserted neighbourhood, through the exhumation of seeds hidden in the earth, can all at once develop an unwonted flora. But nothing of this sort, insists Professor Tommasi-Crudeli, has ever been observed in the case of animal organisms; and therefore he reasserts his opinion that the malaric ferment is constituted by a vegetable, or, in his own language, a schizomycete (*σχίζω*, divide; *μύκης*, a fungus). "The tendency to precipitate conclusions," he adds, "from limited research leads to erroneous interpretations, and can only postpone the solution of a problem so complex as that of the malaric ferment—a problem which must be approached not by an isolated observation, but by the concurrence of a multitude of facts and their verification by experiment."

DR. RICHARDSON'S LECTURES ON ANIMAL OR VITAL MECHANICS.

METHODS OF NATURAL CONSTRUCTION.

THE third lecture of the above course, delivered on Monday, the 17th inst., opened with illustrations of natural constructions in comparison with certain others produced by man. The jointing of bone by the suture was compared with the dovetailing of mechanical art; the fabrics woven by Nature with those woven by man; the vibrating drum of natural formation in the tympanum with the drum and vibrating screen of human design; the natural osseous column with the column erected by the architect; the tubular system of the arteries with the tubular arrangements of human invention for the conveyance of water and other fluids; the sacs or pouches in some animals for water carriage, as in the camel, with the water-holders of human make; the eye as a camera, and the common camera now in such ordinary use. These were all, practically, the same as means for particular ends; and these having been illustrated, the subject was varied in order to introduce details of methods of construction, with comparisons and distinctions between the works of Nature and man. 1. Nature and man go to the same markets for their primary materials. Neither of them works without proper materials, although Nature is able to work with fewer than man, and man often takes structures, such as cotton, which Nature has prepared for him, and applies them to his mechanical purposes. Man also possesses an advantage in that he can bring together his materials from a distance, while Nature only produces at points where the required materials are at hand and ready for application. 2. Nature as well as man requires for her work certain preliminary conditions for construction besides material—that is to say, constructive forces: proper attractions and repulsions, correct degrees of moisture, of temperature, of pressure, of light. These imperfect or unsuitable, the work in both cases is imperfect or wanting in adaptability. Even Nature's crowning work, the highest order of animal construction, the human body, is rendered imperfect if the required conditions are not duly represented. 3. The mechanical works of Nature, like those of man, wear out, but not precisely in the same way. Some parts, those which are elastic, wear out in a manner extremely similar, but Nature seems to have a more systematic destiny for her work than man has for his contrivances. Nature has five successive stages: one of development, a second of maturity, a third of maintenance, a fourth of decline, and a fifth of dissolution. These stages were traced out, and the theory of Flourens, indicating the period of maturity in animals and the multiplication of that period by five for the period of dissolution, was described—man, who had assigned to him twenty-one years as his period of maturity, having 105 years as his period of dissolution, or completed anatomical age for death, and the death taking place, under such fulfilled ordination, from failure at the breathing surface and from a process of anæsthetic sleep. The works of Nature thus grow out of existence, while those of man shake or vibrate out. 4. Natural works as well as human are subject to wear and physical accidents, and both are made to undergo repair, in which work of repair Nature is often most skilful, though she may require directing, as in the case of a broken bone, where she brings together the broken ends, and for a time supports them by an extra deposit, called by the surgeon the callus, which, when it has served its purpose, becomes reduced or passes away altogether. In treating of the wearing out of natural parts, Dr. Richardson was not in favour of the common idea that every part of the body is renovated and replaced by absolutely new material in a limited number of periods—say of seven years—during life. He showed a scar on his own hand from an accidental wound, and which had been there nearly fifty years, as indicating permanency of structure. He referred to memory as proof of the same truth, and he observed that if short periodical structural changes and renovations did really occur, then various diseased organisations, such as disease of the valvular tissues of the heart, ought to pass away and be replaced by new structure, unless diseased structure also reproduced itself. On the whole, he maintained that change was very slow, as slow as life itself, with identity thereby of the *ego*. 5. In her mechanism Nature never traverses laws which man may not. She is not kinder to herself, not less exacting to herself, than to man. She acts in regard to her own mechanism as if she, like man, were obeying a primary power which had provided materials and laid out the conditions. Hence Aristotle had speculated as if in the natural mechanism two powers had been at work, one to give and command, the other to use and carry out by mechanical skill the details of mechanical art. 6. In all the above particulars the works of Nature and of man present much that is in common. When, however, we come to method of work, the difference is as wide as it can be. Nature works from a centre, man works towards a centre; Nature distributes, man concentrates; Nature strikes out or evolves, man brings in and founds or builds. How Nature evolves, and so evolves as to produce perfect organs by coincident growth of parts, formed a striking part of the discourse. Once on this matter all was obscure; now there are some faint lights on it. John Hunter broke ground when, by his experiments on growth of bone, he showed that growth was by deposit from without, attended by absorption from within. Graham broke ground when he divided natural formative structures into colloids and crystalloids, and showed the separation and filtration of crystalline matter through colloidal, with the laying down of the colloidal parts in mechanical order and design. The chemists had broken ground by their proofs that out of inorganic materials they, like Nature, could make organic substances, such as the specimen of artificial urea on the table. The microscopists had broken ground in their industrious labours and discoveries on the subject of natural primary development of structures from cell formation, and on the formation of tissues by the natural arrangement of cells so as to evolve natural constructions. If we could out of the primary elements used by Nature construct a cell that would accrete to itself and give out another cell, the first step of natural construction by evolution would be attained. Without assuming this to be attainable or not, the lecturer passed to a brief description of some recent experiments of his own in micro-electroscopy, from which he explained that by electric decompositions of organic fluids, like blood, he had produced constructions which in many particulars resembled various organic tissues; and concluded with illustrations relating to what he designated "the growth of form" in natural and human combinations.

THE MEDICAL DEFENCE ASSOCIATION AND MEDICAL REFORM.

A MEETING of the Council of the Medical Defence Association was held on the 21st inst., to consider the Medical Bills now before Parliament. Dr. B. W. Richardson, F.R.S., presided. It was resolved: "That, in the opinion of the Council, the Universities of Aberdeen and St. Andrews should each be entitled to send a representative to the General Medical Council, instead of sending one jointly, as provided by the Government Bill." It was also resolved: "That the hon. secretary be requested to convey to Sir Lyon Playfair the above resolution, and to ask if he will receive a deputation from the Association (*a*) in relation to the above; (*b*) on the subject of introducing a clause in the proposed new Act for preventing so-called 'provident dispensaries' being conducted by unqualified persons; (*c*) on introducing a clause relating to the assumption of medical titles." The above resolutions having been forwarded to the Vice-President of the Council, the hon. secretary (Mr. George Brown) has received the following reply:—

"Privy Council Office, May 24th, 1886.

"Sir,—I am directed by Sir Lyon Playfair to acknowledge the receipt of your letter of the 22nd, and to say that the last two subjects referred to therein (the conduct of so-called provident dispensaries and the assumption of medical titles by unqualified persons) are not dealt with by the Bill, of which the scope is definite and could not be enlarged. With regard to the representation of the Universities of Aberdeen and St. Andrews, Sir Lyon Playfair hopes that the question may be decided to-night in committee, in which case it will be unnecessary to trouble your Association to send a deputation on the subject.

"I am, Sir, your obedient servant,

"J. W. MACKAIL."

WILLS OF MEDICAL MEN.

THE will of Mr. John Cooper Forster, formerly President of the Royal College of Surgeons, late of 29, Upper Grosvenor-street, who died on March 2nd last, was proved on the 13th ult. by Mr. Stuart Forster, the son, and Mr. Arthur Edgell Eastwood, the executors, the value of the personal estate exceeding £25,000. The testator bequeaths to his wife, Mrs. Adela Forster, his furniture, books, pictures, plate, jewellery, and effects; and there are some legacies and annuities to servants charged on his real estate. All his freehold and copyhold property he leaves to his wife for life, and then to his said son. The residue of the personalty is to be held upon trust for his wife for life, and at her death as to one-fifth for his granddaughters, Undine and Elsa Emily Dixon, one-fifth for his danghter, Mrs. Jessie Tamplin, and three-fifths for his daughters, Rose and Anna Forster.

The will and codicil of Mr. George Ord, retired surgeon, of Brixton-hill, Surrey, were proved on April 20th by Mr. William Miller Ord, physician, and Mr. George Rice Ord, surgeon, the sons, the executors, the value of the personal estate amounting to over £24,000. The testator leaves three-fifths of his real and personal estate to his son, William Miller, and two-fifths to his son, George Rice.

The will and four codicils of Mr. Francis Burdet Courtenay, surgeon, of 2, Chandos-street, Cavendish-square, who died on March 15th last, were proved on the 3rd inst. by Mrs. Frances Maria Lambert, Mr. Francis Hoare, and Mr. Edward Horseman Bailey, the executors, the value of the personal estate amounting to over £16,000. The testator bequeaths legacies to his daughter, grandchildren, a servant, and others. The residue of his property he leaves upon trust for his daughter, Mrs. Lambert, for life, and then for her children or more remote issue as she shall appoint.

The will of John Fremlyn Streatfeild, F.R.C.S., late of 15, Upper Brook-street, who died on March 18th last, was proved on the 3rd inst. by Mrs. Georgiana Maria Streatfeild, the widow, the Rev. Arthur Benjamin Cotton, and Colonel Robert Champion Streatfeild, the executors, the value of the personal estate amounting to over £14,000. The testator makes some bequests in favour of his wife, his mother, and his executors; his freehold estate at Chigwell, Essex, at Canterbury and Westerham, Kent, and the residue of his real estate, he leaves to his wife for life or so long as she shall remain unmarried, and then he settles the same on his son Thomas. The residue of his personal estate he leaves upon trust for his wife so long as she shall remain unmarried, and then for all his children (except the child who shall succeed to his real estate) in equal shares.

The will and four codicils of Mr. Richard Stocker, late of 29, Upper Montagu-street, Montagu-square, surgeon, who died on Feb. 25th last, have been proved by Mr. John Sherwood Stocker, the son, and Mr. Thomas Dence, the executors, the value of the personal estate amounting to upwards of £7000. With the exception of a complimentary legacy to his executor, Mr. Dence, the only legatees under the will are the testator's sons, Richard Charles Southby Stocker and John Sherwood Stocker.

The will of Thomas Spencer Cobbold, M.D., of 74, Portsdown-road, Paddington, who died on March 20th last, was proved on April 19th by Charles Spencer Waller Cobbold, M.D., the son, and Mr. John Henry Hortin, the executors, the value of the personal estate amounting to over £12,000. The testator gives his leasehold residence with the furniture and effects and £100 to his wife, Mrs. Frances Philippa Cobbold; his microscopic cabinet of entozoa to his said son; all his books on helminthology to the Linnæan Society of London, Burlington House, for the library; and pecuniary and specific legacies to children and others. The residue of his property he leaves to his wife.

The will of John Storrar, M.D., formerly of 113, Ladbroke-grove, but late of Stratheden House, Blackheath, who died on March 10th last, was proved on April 13th by Mrs. Helen Storrar, and Mr. Robert Storrar, the brother, the executors, the value of the personal estate amounting to over £4000. There are bequests to his brother, James Russell Storrar, and his wife, and to his late wife's niece; and the residue of his property he gives to his said brother Robert.

The following legacies have recently been left to hospitals and other charitable institutions:—Mrs. Frances Acton, of 106, Elgin-crescent, Notting-hill, £500 to the Royal Hospital for Incurables, West-hill, Putney.—Mr. Edward Cohen, of 111, Harley-street, Cavendish-square, and of Windermere, Westmoreland, £200 to the Middlesex Hospital, Charles-street, and £100 each to St. Mary's Hospital, Paddington, and University Hospital, Gower-street.—Mr. Richard Henry Vade Walpole, formerly of Upper Brook-street, Grosvenor-square, but late of Suffolk Hall, Cheltenham, whose personal estate amounts to over £185,000, £200 to the Royal Hospital for Incurables, West-hill, Putney; £100 each to the Cancer Hospital, Brompton, St. Mark's Hospital, City-road, the Fever Hospital, Pelley, Leckhampton, Cheltenham, and the Metropolitan Free Hospital, Spitalfields; and the whole of the large residue of his personal estate in equal shares to the Westminster Hospital, Broad Sanctuary, Charing-cross Hospital, King's College Hospital, Portugal-street, St. Mary's Hospital, Paddington, the London Hospital, Whitechapel, the Royal Free Hospital, Gray's-inn-road, the London Fever Hospital, Liverpool-road, the City of London Hospital for Diseases of the Chest, Victoria-park, the Norfolk and Norwich Hospital, the Cheltenham Hospital and General Dispensary, the Great Yarmouth Hospital, and the British and Foreign Sailors' Home, Great Yarmouth.—Dame Anna Maria Hare-Clarges, of the Crystal Palace Hotel, Norwood, £500 each to the Royal Hospital for Incurables, Putney, and the Taunton Hospital or Infirmary, Somersetshire.—Mr. Arthur Blewert Bryer, of 7, Kennington-park-road, £200 to the Royal South London Dispensary for the Relief of the Sick Poor.—Mr. Foster Connor, of Lea Court, Bangor, co. Down, and of the Linen Hall, Belfast, £500 to the Belfast Royal Hospital.—Mr. Samuel Ellis, of 28, Gracechurch-street, tea merchant and grocer, £100 to the Yeatman Hospital, Sherborne.—Mr. Charles George Johnson Da Silva, of Bride-lane, Fleet-street, merchant and medicine dealer, and of Burntwood, Wandsworth-common, such part of the residue of his personal property as may by law be applied for charitable purposes, to the Royal Medical Benevolent College, to found three exhibitions of £50 per annum each, tenable for three years, for boys educated at the College and proceeding to the universities, and to pay £20 per annum each to twenty-six poor pensioners of the said college.—Mr. Alfred Burges, late of Worthing, £3500 to such charitable institutions or societies, and in such shares, as his trustees in their absolute discretion shall think fit.—Miss Elizabeth Lancaster, of Stanmer House, Suffolk Lawn, Cheltenham, £250 each to the Cheltenham General Hospital and Dispensary, the Cheltenham Samaritan Fund and Dispensary, a branch of the said Hospital, the Scarlet Fever Ward or branch of the Delancy Hospital, and the Small-pox Ward or branch of the said Hospital.—Mr. Thomas James Stallard-Penoyre, late of 54, Wilbury-road, Hove, £50 to the Cancer Hospital, Brompton.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Milton Rural District.—Dr. Sutton explains the value of the infectious hospital which was jointly erected by this authority and the Sittingbourne Local Board of Health, a sudden outbreak of small-pox having been checked by it, in addition to its having been found useful in other diseases. Rainham has stood in need of much amelioration, the report on this place taking note of polluted drinking-water, offensive closets, defective drainage, overflowing cesspools, and insanitary slaughter-houses. All these conditions are, according to the report, remedied. We trust the remedies are permanent, and not merely of a temporary sort. The death-rate for 1885 was low—namely, 13·1 per 1000.

Jarrow Urban District.—The great depression of trade which has been so peculiarly felt in Jarrow has not, according to Dr. Munro, produced any appreciable effect on the death-rate for last year, that rate standing at 22·1 per 1000 as opposed to 23·4 during the previous two years. The zymotic rate was high, reaching 44 per 10,000 of the popula-

Digitized by Google

tion; measles, scarlet fever, and whooping-cough being the three diseases which caused most deaths. Scarlet fever was largely maintained by attendance at one of the elementary schools, and since obscure cases baffled Dr. Munro's efforts to limit the spread of the disease by the exclusion of scholars from infected houses, it was at last found necessary to close the school under the provisions of the Education Code. The school was well cleansed whilst closed, and the result was that after its reopening there was no recrudescence of the disease in connexion with the re-assembling of the children. This result was favoured by the system of compulsory notification of infectious diseases in force within the borough. During the year 714 cases were notified to the authority, no less than 264 being cases of scarlet fever, and in this connexion it is satisfactory to note that an infectious hospital is in course of construction. This matter has been a tedious one in Jarrow. Economical reasons prevented a joint hospital being erected for Jarrow and the neighbouring towns of South Shields and Hebburn, and the result is that at last Jarrow has to act alone, at a greater cost than the joint scheme would have involved, and with the prospect of larger permanent expenses of maintenance than would otherwise have been involved. Apart from these considerations, however, there are certain advantages in each sanitary authority having its separate hospital.

South Shields Urban District.—Dr. Munro gives the death-rate of this district during 1885 as 22·3, much the same as in the previous year, the zymotic rate being 32 per 10,000, which was in excess of that for the previous four years. Small-pox has now been introduced in thirty-three instances during three and a half years, and as regards each first case Dr. Munro is able to add that it was removed to hospital. The result of this action has been that in no single instance has there been any extension of the disease after it became reported to the Health Office. Scarlet fever caused no less than 76 deaths during the year, and the failure to cope with it satisfactorily is in part ascribed to the absence of compulsory notification. Again and again efforts in the direction of prevention were ultimately found to have been futile, owing to some unknown case a few doors off, or just on the other side of the street. The infectious hospital received 126 cases, including Dr. Munro himself, who, having contracted scarlet fever in the performance of his official duties, showed an example by placing himself under isolation in the manner provided by the authority. In connexion with the general sanitary work carried out, proceedings under the Food and Drugs Act are specially adverted to, Dr. Munro finding himself hampered by a decision of the Town Clerk to the effect that since milk for analysis must, according to the Act, be procured "at the place of delivery" and "in course of delivery," the taking of samples from carts entering the town would not justify legal proceedings under the Act. The report proceeds to say that the sooner the section is cleared of this ambiguity, and it is provided that samples of milk may be taken on the highway, the better for the consumer and the worse for the adulterator.

Northampton Urban District.—The birth-rate of Northampton has steadily fallen from 41·3 per 1000 in 1878 to 32·6 in 1885; the death-rate for the latter year was 15·5 per 1000. Measles, whooping-cough, and diarrhœa were the three preventable diseases which caused the largest mortality, and they led to a largely increased zymotic rate. Some use was made of the make-shift isolation hospital, but for the diseases just specified isolation is rarely resorted to, and it is doubtful how far it would be useful to urge it on sanitary authorities. From Mr. Cogan's account of the current sanitary work, inspection of the district would appear to be systematically carried out, with the result of an abatement of many injurious nuisances. Disinfection is largely resorted to where needed, and there is now a prospect that in the very important matter of water-supply the town will before long be freed from the serious danger to which it has been put by previous failure in the matter of deep well sinking.

Toxteth Park Urban District.—This favoured suburb of Liverpool had a death-rate of only 13·4 per 1000, and even this is decidedly in excess of the mean for the previous four years. Of the diseases usually grouped together as zymotic 9 were from whooping-cough and 4 from diarrhœa; but there was also some small-pox and scarlet fever, of which details are given by Dr. Steeves, and special action as to school attendances, disinfection, &c., had to be taken in consequence. It is, however, satisfactory to know that the sanitary authority are in earnest in their endeavour to secure a hospital for the isolation of first attacks of infectious diseases, and that they have already taken preliminary steps to secure a site. Attention has been given to the sanitary state of bakehouses and dairies, and systematic inspection of the district has been carried out.

Sittingbourne Urban District is also under Dr. Sutton's jurisdiction, and both scarlet fever and small-pox were stayed by the aid of the hospital already referred to. An excellent water-supply is mentioned as having done much to diminish outbreaks of enteric fever, 1400 out of 1543 houses being now supplied from the public works. Constant scavenging is also maintained throughout the town. The annual death-rate reached 17·3 per 1000, and the birth-rate was 43·6.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6106 births and 3254 deaths were registered during the week ending May 22nd. The annual death-rate in these towns, which had been equal to 20·6 and 19·1 per 1000 in the preceding two weeks, further declined last week to 18·7. During the first seven weeks of the current quarter the death-rate in these towns averaged 19·8 per 1000, and was 3·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·5 in Derby, 13·0 in Brighton, 13·9 in Bristol, and 16·1 in Hull. The rates in the other towns ranged upwards to 22·7 in Halifax, 24·1 in Portsmouth, 25·2 in Manchester, and 34·0 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 367 and 324 in the preceding two weeks, further fell last week to 286; they included 108 from measles, 87 from whooping-cough, 27 from "fever" (principally enteric), 27 from diarrhœa, 21 from scarlet fever, 15 from diphtheria, and 1 from small-pox. No death from any of these zymotic diseases was recorded last week either in Birkenhead or Huddersfield, whereas they caused the highest death-rates in Blackburn, Portsmouth, and Preston. The greatest mortality from measles occurred in Blackburn, Bolton, and Preston; whooping-cough showed the highest proportional fatality in Salford, Manchester, and Cardiff; and "fever" in Portsmouth. The 15 deaths from diphtheria in the twenty-eight towns included 9 in London, 2 in Liverpool, and 2 in Leeds. Small-pox caused 1 death in Liverpool, but not one in London or in any of the twenty-six large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had increased in the previous eight weeks from 7 to 31, had further increased to 35 on Saturday last; 10 new cases were admitted to these hospitals during the week, against 11 and 9 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 309 and 293 in the preceding two weeks, further declined last week to 282, and were 33 below the corrected weekly average. The causes of 66, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Norwich, Sunderland, and in four smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Newcastle-upon-Tyne, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·1, 22·3, and 22·2 per 1000 in the preceding three weeks, further declined to 21·8 in the week ending May 22nd, and exceeded by 3·8 per 1000 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 13·7 and 18·1 in Dundee and Aberdeen, to 22·9 in Perth and 25·4 in Glasgow. The 538 deaths in the eight towns showed a decline of 10 from the number returned in the preceding week, and included 11 which were referred to whooping-cough, 10 to measles, 7 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 5 to diphtheria, 5 to scarlet fever, and not one to small-pox; in all, 44 deaths resulted from these principal zymotic diseases, against 62 and 55 in the preceding two weeks. These 44 deaths were equal to an annual rate of 1·8 per 1000, which slightly exceeded the mean rate from the same diseases in the twenty-eight

Digitized by Google

English towns. The fatal cases of whooping-cough, which had declined from 21 to 14 in the preceding three weeks, further fell last week to 11, of which 7 occurred in Glasgow and 3 in Edinburgh. The 10 deaths referred to measles showed a decline of 7 from the numbers in the previous week, and included 8 in Edinburgh. The 7 fatal cases of diarrhœa were fewer than those returned in any recent week, and less than half the number in the corresponding week of last year. The deaths from "fever," which had been 2 and 5 in the preceding two weeks, further rose last week to 6, of which 2 occurred in Glasgow and 2 Aberdeen. The 5 fatal cases of diphtheria exceeded by 2 the number in the previous week, and included 3 in Edinburgh and 2 in Glasgow. The 5 deaths from scarlet fever were all recorded in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 108 and 103 in the preceding two weeks, rose again last week to 119, and exceeded by 12 the number in the corresponding week of last year. The causes of 66, or 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 27·8 and 23·8 per 1000 in the preceding two weeks, rose again to 28·7 in the week ending May 22nd. During the first seven weeks of the current quarter the death-rate in the city averaged 27·1 per 1000; the mean rate during the same period did not exceed 18·6 in London and 19·3 in Edinburgh. The 194 deaths in Dublin last week showed an increase of 36 upon the low number in the previous week, and included 6 which were referred to the principal zymotic diseases, against 14 and 8 in the previous two weeks; 2 resulted from "fever" (typhus, enteric, or simple), 2 from whooping-cough, 1 from diphtheria, 1 from diarrhœa, and not one either from small-pox, measles, or scarlet fever. These 6 deaths were equal to an annual rate of 0·9 per 1000, the rate from the same diseases being 1·6 in London and 3·1 in Edinburgh. The fatal cases of whooping-cough, which had been 7 and 2 in the preceding two weeks, were again 2 last week. The deaths referred to whooping-cough, which in the previous two weeks had been 1 and 3, declined last week to 2. Two inquest cases and 1 death from violence were registered; and 53, or more than 27 per cent., of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable increase upon those returned in the previous week. The causes of 30, or more than 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon George Scott Davie, M.D., is granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major Christopher John Weir, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon.

ADMIRALTY.—Royal Naval Artillery Volunteers (Bristol Brigade): Francis William Slow Wicksteed, M.B., M.R.C.S., to be Surgeon.

The following appointments have been made:—Staff Surgeon Alex. R. Joyce, to the *Cleopatra*; and Staff Surgeon J. W. H. Howton, to the *Daring*.

ARTILLERY VOLUNTEERS.—1st London (City of London): James William Thornton Gilbert, Gent., to be Acting Surgeon.

ENGINEER VOLUNTEERS.—1st Gloucestershire (the Western Counties): Surgeon T. S. Ellis is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—3rd Durham (the Sunderland): Mitchell Hunter, Gent., M.D., to be Acting Surgeon.—2nd Volunteer Battalion, the Hampshire Regiment; Henry Wm. Russell Bencraft, Gent., to be Acting Surgeon.

THE VOLUNTEER MEDICAL STAFF CORPS.—Woolwich Company: James Francis Henry Bottrell and Charles Henry Hartt, to be Surgeons.—Edinburgh Company: Charles W. Cathcart, M.B., and David Hepburn, M.B., to be Surgeons.

THE annual meeting in connexion with Dr. Barnardo's Homes for Orphans and Destitute Children was held on the 22nd inst.

"Audi alteram partem."

THE MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

To the Editor of THE LANCET.

SIR,—The fourteenth annual meeting of the American Public Health Association is to be held at Toronto during the first week in October, and I have been requested by Dr. C. W. Covernton, the first vice-president, to bring the meeting to the notice of English sanitarians, in the hope that they may be willing to visit Canada on that occasion. In addition to the reading and discussion of papers on various matters relating to hygiene set out in the circular I beg to enclose, it is desired to establish an International Congress of Hygiene, and to get international protective laws passed safeguarding Europe from the importation of yellow fever and the continent of America from small-pox and cholera.

If a number of persons, amounting to fifty, elect to go to Canada, they would be conveyed from London to Toronto and back, first class, for twenty guineas a head; while for another twenty guineas those who might desire to see more of the country would be carried by the Canada Pacific Railway along a most charming line of country from Quebec, Montreal, or Toronto to the terminus of the road—Vancouver, or to any part of British Columbia they might elect to stop at on the line,—and return to either of the above starting-points. I shall be happy to receive the names of persons who would like to make up a party, and shall be pleased to give any more detailed information. As this invitation is doubtless meant as an international courtesy, I make no apology for trespassing on your space, but thank you, in anticipation, for affording me the means of bringing to the notice of English sanitarians the favourable opportunity which presents itself for spending a delightful autumn holiday among our colonial and American brethren.

I am, Sir, yours obediently,

C. E. SAUNDERS, M.D.,
Hon. Sec., Society of Medical Officers of Health.

PARALYSIS OF LARYNGEAL MUSCLES AND CORTICAL CENTRE FOR PHONATION.

To the Editor of THE LANCET.

SIR,—In your issue of to-day we observe two editorial annotations referring to the above subjects, upon which we hope you will allow us to make a few remarks.

In the first you comment upon a case of paralysis of the adductors of the right vocal cord, reported by M. Charazac of Toulouse, and explained by that author to be due to compression of the right recurrent laryngeal nerve by a cystic goitre. This case, M. Charazac believes, sufficiently proves that the general law proposed by one of us some years ago—viz., that in *all* cases of progressive affection of the roots or trunks of the laryngeal motor nerves, due to *organic* lesions of the latter, the *abductor* fibres and muscles first succumb—cannot be maintained, and that a paralysis thus produced may, indeed, show itself first in the *adductor* muscles. Now, the law referred to was established not merely on clinical observation, but on the solid ground of morbid anatomy, and we may now add to this experimental evidence, which we have been accumulating for several months. Consequently, we consider that it is only fair to admit any contention to the contrary as in the least degree cogent, when it is supported by the *exhibition of specimens*, showing that in cases in which the roots or trunks of the motor nerves of the larynx were attacked by organic disease, the *adductor* muscles only had undergone degenerative changes, whilst the abductor or abductors remained unaltered.

Concerning the second annotation—viz., the one referring to M. Garel's case of paralysis of the left vocal cord, attributed by that author to two patches of softening situated in the third frontal convolutions of both hemispheres,—we

Digitized by Google

confess we are quite unable to understand the grounds upon which he bases this opinion. We have been for some time engaged in carrying out an extensive series of researches into the localisation of the centres for the phonatory movements of the vocal cords in the cerebral cortex. In these experiments, which have been performed on monkeys, dogs, cats, and rabbits, and the results of which will soon be published in full, we have been able to confirm the results on dogs obtained by Dr. Krause of Berlin—namely, that the phonatory function of the vocal cords of the dog is bilaterally represented in the gyrus præfrontalis of each hemisphere. We find that this state of things apparently varies with different classes of animals. (In the monkey, we may mention in passing, we have found that the phonatory centre is situated in that part of the brain which corresponds exactly to the speech-centre in man; only it is bilaterally represented.) Under *all* circumstances—i.e., in *all* animals—however, we have seen (*a*) that stimulation of this centre in *one* hemisphere produced *bilateral* action of the vocal cords, and (*b*) that the effect was exactly the same whether the *right* or the *left* hemisphere was stimulated. That *bilateral* representation also exists in *man*, we consider to be established by the fact that aphasia is hardly ever accompanied by aphonia, which it necessarily would be if the phonatory centre were represented in the *left* third frontal convolution only.

Now, in the face of these facts, we are simply unable to understand in M. Garel's report how it came about that *bilateral* cortical mischief produced only paralysis of *one* vocal cord? Would it not seem more likely that some other lesion, by which this unilateral paralysis could have been more naturally explained, was present and overlooked?

We are, Sir, yours truly,

FELIX SEMON.

The Brown Institution, May 22nd, 1886. VICTOR HORSLEY.

THE LUNACY ACTS AMENDMENT BILL.

To the Editor of THE LANCET.

SIR,—In the memorandum on the Lunacy Acts Amendment Bill it is stated—"The principle of the Scotch procedure has been adopted with somewhat fuller elaboration of details. The Bill provides for the appointment of special justices to make orders for the reception of lunatics not paupers, and, except in cases of urgency, a person not a pauper is not to be confined as a lunatic without an order of a County Court judge, stipendiary magistrate, or justice, to be obtained upon a petition presented, if possible, by a relative, and accompanied by two medical certificates." But in this assimilation of English to Scotch procedure it must not be supposed that there is any assimilation of the Scotch principles of lunacy administration. If lunatics are to be confined in asylums on the order of a magistrate, there can be little doubt that our system is very much superior to that which obtains in England at the present moment. It is a calm judicial procedure applied to all cases equally, be they rich or poor. It works easily and smoothly with us, no difficulties arise in its employment, and it affords a certain degree of assurance to the public that all matters connected with the seclusion of the insane are conducted decently and in order. No feeling of doubt or suspicion exists in Scotland, and since 1859 (the date of the first Scotch Lunacy Act) not a single case has come into court arising out of circumstances occurring subsequently to that date in which suspicion has been thrown on the propriety of the confinement or detention of an insane person. But is this happy state of things due to the sheriff's order? I think not; or, if it is, it is only to a very small extent. The reason of the smooth working of lunacy matters in Scotland is mainly due to two circumstances—(1) It is a small country, with a limited number of lunatics, and (2) we have a sufficient and efficient General Board of Lunacy. In a comparatively small community like ours everybody knows everybody. The sheriff knows the certifying doctors either personally or by reputation, or he can readily procure information regarding them should he desire it. The second circumstance, the constitution of our General Lunacy Board, is, however, of much greater importance. This board consists of an unpaid chairman, two unsalaried legal and two salaried medical commissioners, who supervise twenty-nine asylums, sixteen poorhouse wards for the reception of pauper lunatics, and three training institutions for imbecile children. These various institutions contain about 6500 patients. Each of the medical commissioners visits each asylum at least twice a year. Now the practical result of this is that these officers become personally acquainted with every case of any particular importance—important, I mean, as regards the necessity or propriety of detention. In England the General Board of Lunacy consists of an unpaid chairman, and two unpaid and three paid legal commissioners, and two unpaid and three medical commissioners. In visiting the various asylums a legal and a medical commissioner hunt in couples. What practical use this is I fail to understand, nor have I ever received a reasonable explanation from any one competent to judge. In Scotland it would sound to us simply ridiculous were it proposed to start an Advocate or a Writer to the Signet in company with a doctor to make tours round asylums. I have asked many English superintendents of asylums of long and great experience, two retired and some acting inspecting officers, whether they ever knew of a case in which the slightest benefit resulted from the presence of a visiting legal commissioner. The answer was invariably No. The strongest advocate of this system may be challenged to produce a single case in its support—a case in which any legal difficulty had arisen which could not have been as well settled by reference to the General Board sitting in London. Legal commissioners are absolutely useless, and waste public money which might be applied in other directions.

The three medical commissioners have to visit something like 140 asylums, each pauper asylum being visited once, and each private one twice yearly, but not by the same men time after time. I submit that considering the enormous size of many of these institutions, the immense number of patients to be seen, and the great extent of the perigrinations, it is impossible for the English medical commissioners to have the same knowledge of individual patients as ours have. Three such officers inspect some 50,000 lunatics; whereas in Scotland something like 6500 are inspected by two commissioners. It has been suggested that our officials are not overworked—that, in fact, one medical commissioner would be sufficient; but, apart from all other considerations (and there are many), if these two officials maintain public confidence their not extravagant salaries are well-expended public money.

The principles of the Scotch system are—limited areas and ample supervision; and without these magistrates' orders will be futile. My humble opinion is that the line reform should take in England should be in the direction of the adoption of Scotch principles, not merely of Scotch legal procedure, and in this wise: First, that the constitution of the General Board of Lunacy should be improved by the conversion of legal into medical commissioners, the number of whom should be increased to ten or twelve. All legal difficulties could be considered by a standing counsel, by an efficient legal secretary to the Board, or by honorary legal commissioners sitting in London. Secondly, that England and Wales should be broken up into lunacy districts, each of which should contain not more than 10,000 lunatics. Thirdly, that two medical commissioners should be appointed *to reside* in each district, the asylums of which they should visit regularly twice a year. Periodical meetings of the General Board should be held in London, which one commissioner from each district should attend.

I believe by this means public confidence in England would be established, and that the same elasticity of management as exists in Scotland would be obtained. The Scotch Board, having the whole of our institutions immediately under its eye, can and does allow great latitude of action in the management of individual asylums, which is impossible under existing circumstances in England, where there is a much greater tendency towards officialism and red-tape than with us.

It may be fairly argued that one reason of the absence of doubt and suspicion in Scotland is the small number of private asylums. This is an argument of no small weight, as most of the legal difficulties have arisen in them; but as such institutions are not likely to be abolished, at least for some considerable time, in England, the strength of my contention is not weakened.

I am, Sir, yours obediently,

Edinburgh, May 15th, 1886. JOHN BATTY TUKE.

RÖTHELN OR RUBELLA.

To the Editor of THE LANCET.

SIR,—Your correspondents on the above subject will find it stated in Quain's Dictionary, under the latter name, that "enlargement of the lymphatic glands in the neck is an early symptom, most marked in children." It is one that I have noted in three previous descriptions given by me of this exanthem.—I am, Sir, your obedient servant,

Orchard-street, W., May 24th, 1886. WILLIAM SQUIRE, M.D.

"THE MEDICAL BILLS."

To the Editor of THE LANCET.

SIR,—In the interest of the profession, permit us to say on behalf of the Medical Alliance Association that the "clause" sent to you by Dr. Wiglesworth of Liverpool, and which you published on Saturday last, does not restrict the practice of medicine or surgery by unqualified persons, nor does it prevent the assumption of medical or surgical titles by persons holding unrecognised medical qualifications.

We are, Sir, yours faithfully,

PRIDHAM, PIPER, & Co.,
Solicitors to the Medical Alliance Association.

Old Serjeants' Inn, W.C., May 17th, 1886.

BELFAST.

(*From our own Correspondent.*)

QUEEN'S COLLEGE: THE MEDICAL STUDENTS AND THE ROYAL UNIVERSITY EXAMINATIONS.

ON the 21st instant a joint meeting of graduates and undergraduates was held at Queen's College "to discuss certain grievances which the candidates from the Belfast Medical School have suffered at the recent examinations of the Royal University of Ireland." There was a large attendance, as the students feel deeply interested in the matter. Dr. O'Neill, surgeon to the Royal Hospital, presided. The Chairman having spoken, and a considerable number of those present having given expression to their views on the matter, the following resolutions were unanimously adopted:—1. "Whereas, of the candidates presenting themselves for the various examinations in medicine in the Royal University, Ireland, about 40 per cent. receive their professional education in the Belfast Medical School; and whereas at the first medical examination, of the four examiners only one—at the second medical examination, of the nine examiners only two—and at the M.B. examination, of the thirteen examiners only one, are from the Belfast School; and whereas we are convinced that the students of the Belfast Medical School are thereby placed at a great disadvantage, and the Belfast School materially injured: resolved that we do hereby direct the attention of the Senate of the said University to the existence of this anomaly, and that we respectfully request them to remove it by giving a fair and proportionate representation to the Belfast Medical School on the Examining Board." 2. "That the method of conducting some of the oral examinations is eminently unsatisfactory, especially the oral examinations in practical physiology at the M.B. degree examination, in which sufficient time is not allowed to the candidates for the amount of work to be done; and that in the examinations in medicine, surgery, midwifery, and gynæcology questions are asked and methods of treatment required which are not found in the standard textbooks, or recognised by the leading medical schools of the United Kingdom; and not only so, but the methods taught and advocated by the leading London physicians and surgeons are in some instances not accepted, and that on the part of some of the examiners there is a marked want of courtesy towards the candidates." 3. "That in a great many instances the questions are unscientific and devoid of practical importance, and that the tendency of the questions in medicine, surgery, midwifery, and gynæcology has been of such a nature as to render it a matter of absolute necessity to spend some time in Dublin at considerable expense and inconvenience under the charge or care of a 'grinder,' in order to be acquainted with the peculiarities and the special lines of treatment advocated by the several examiners, as in many cases these cannot be learned from the standard text-books." 4. "That additions have been made to the courses of examination without sufficient notice having been given." 5. "That copies of the foregoing resolutions be sent to the Lord-Lieutenant, Chief Secretary, Under Secretary, and to the Senate and examiners of the Royal University, and that the chairman and secretary be appointed as a deputation to wait on the Senate at their next meeting, and to present their own views to him." This deputation waited on the Senate of the Royal University on the 25th. Dr. O'Neill of Belfast, having read the resolutions (given above), stated that it was not the Queen's College nor the Belfast Royal Hospital that he represented, but the entire body of students, who attended every means given for medical instruction in Belfast. Having referred to the unsatisfactory method of conducting some of the oral examinations, to the method adopted with regard to examinations as to treatment of cases, he said no man was safe unless he answered according to the Dublin system of treatment. He complained that in many instances questions unscientific and devoid of any practical importance were sometimes put, and affirmed that it was necessary, in order to cope with the present extraordinary system, that students should come to Dublin, and be coached by grinders so as to become acquainted with the peculiarities of examiners and the several lines of treatment advocated by these examiners. In conclusion, he asked that a commission might be appointed to inquire into the allegations made, and said they were prepared to abide by the result. Lord Emly, the Vice-Chancellor, who presided, observed that Dr. O'Neill had presented the case of the Belfast Medical School fully and forcibly. The grievances complained of would receive the very best attention of the Senate. The latter decided to refer the matter to a special committee, consisting of the Standing Committee and medical members of the Senate, for consideration and report.

BELFAST ROYAL HOSPITAL.

In the report read at the quarterly meeting (May 24th), it was stated that during the quarter there were 459 in-door patients, while during the same period there were treated 2718 extern patients. The financial section of the report showed that the donations and bequests amounted to £356 19*s.* 3*d.* The general subscriptions, however, compared with last year, showed a falling off of £31 9*s.* 9*d.* The ordinary income had not kept up with the ordinary expenditure. When all the April accounts were paid there would be an amount due against the hospital of £579 17*s.* 11*d.* The board recorded with deep regret the death of their president, Lord Shaftesbury, as well as of one who had taken a deep interest in the charity, Sir Wm. G. Johnston, D.L. Saturday, May 29th, has been set apart by the board as Hospital Saturday, and great exertions are being made to render the effort a success.

THE MEDICAL SCHOOL.

The summer session has now commenced, and teaching is going on regularly at the College and Royal Hospital. Dr. Cuningham, Professor of Natural History, is conducting a special class at the College in Practical Biology for the benefit of students in these subjects, it being now necessary for medical students to pass a practical examination in zoology at the Royal University.

THE ST. JOHN AMBULANCE ASSOCIATION.

In the report presented at the first meeting of the Belfast Branch of this Association on May 24th, it is stated that the organisation of the Belfast Centre is complete. Since the foundation of the centre, courses of lectures have been delivered in Belfast, Limavady, Omagh, and Portrush. Seventy-one members have passed the examinations and received certificates from the Association. Dr. John Moore is the Honorary Secretary.

Belfast, May 25th.

HOME HOSPITALS.—At the eighth annual meeting of the Home Hospitals Association, on the 20th inst., it was reported that there had been during the year 625 applicants for admission, of whom 282 were admitted. The average number of patients in the hospital at one time was 19, and their average stay was 24 days. The balance sheet showed that the year's income amounted to £4576, and the expenditure left a balance of £787.

PARIS.

(From our own Correspondent.)

THE ABUSE OF ALCOHOL.

OWING to the ravages that are being committed by alcoholism in this country, the authorities have felt it high time to interfere, and to adopt such measures as will prevent the physical and moral degradation to which the population is being reduced by the excessive abuse of spirits, and especially spirits of an inferior quality. The subject has been brought before the Senate, which ordered a commission to investigate the matter. The reporter suggested that whatever other measures be taken, legislative or otherwise, they would be of little or no avail unless the rectification of the alcohols delivered for consumption be exacted. Among the other measures proposed by the commission to reduce alcoholism to a minimum may be mentioned increase of the duty on alcohol, the prevention of "vinage," or the addition of alcohol to wines, and the reduction of the number of "cabarets" or wine-shops. As regards vinage, M. Girard, Director of the Municipal Laboratory of Paris, who was consulted on the subject, stated that experiments performed by him showed that the addition of alcohol to wine destroyed the properties of the latter in precipitating a portion of the tartaric acid and extractive matters it contains. Dr. Dujardin-Beaumetz, in the name of the Council of Hygiene, declared that the process of vinage profoundly altered the wine without in any way improving it, except for the purpose of preservation, which is of advantage only to the wine merchant. Dr. Brouardel, the President of the Society of Hygiene, made a statement to the same effect, and added that vinage was a source of great danger to the public health. Although this process was approved of by the Academy of Medicine in 1870, it is presumed that if it were now consulted it would express a different opinion, as the study of the physical and chemical constitution of alcohols, as well as of their toxic properties, has made considerable progress since that time. In connexion with this subject, I may note that the Academy of Sciences has been furnished with some startling facts respecting the production of the liquid commonly sold as cheap brandy. Out of more than 50,000,000 gallons of alcohol distilled annually, not quite 500,000 gallons, according to M. Girard, were distilled from the grape. The greater portion of spirit is obtained from grain, which, if sufficiently rectified, is not unwholesome; but, this being very rarely done, the spirit is noxious. Alcohol is also distilled from apples, pears, potatoes, and beetroot, all of which contain poisons of various kinds.

THE IDENTIFICATION OF CRIMINALS BY ANTHROPOMETRY.

About two years ago Dr. Bertillon, Director of the Statistical Department of the Prefecture of Police, introduced a system of anthropometry for the purpose of identifying criminals and others when arrested. This system has been attended with the best results, as it was not always easy to identify criminals by simple photographs. Since the adoption of anthropometry many old offenders have been recognised, and dealt with according to their offences.

Paris, May 25th.

BERLIN.

(From our own Correspondent.)

VIRCHOW'S JUBILEE.

TO-DAY three decennials have passed since Professor Rudolph Virchow commenced his duties as teacher of pathological anatomy in Berlin. Here he studied, and, deducting the seven years in which he occupied the chair at Würzburg, he has displayed great activity in practice since 1844 in the city. His cellular pathology, too, which procured for his name a world renown, has its roots in the soil of medical Berlin. Under the guidance of Johannes Müller, Theodor Schwann pursued his studies, in which he proved that the [illegible] consists of cells. Virchow [illegible] Reymond, Remak, [illegible] (who died in 1852). Next to Johannes Müller, it was Robert Froriep, professor at the Charité, to whom Virchow was most indebted. The former was his guide in the paths of general biology and pathology, but it was the latter who introduced him to practice and to the methods of observation. Later Virchow became the successor to his two masters—to Froriep in 1846, who out of regard to his family removed to Weimar; and to Johannes Müller in 1856, who welcomed Virchow on his return to undertake the duties of the chair of Pathological Anatomy, which till then had been united with that of Anatomy and Physiology. Virchow's career as teacher began with his appointment as prosector at the Charité. In the summer of 1846 he gave his first lecture on Pathological Anatomy. Till then Vienna had been without dispute the home of pathological anatomy. This branch had been neglected in Berlin. At the commencement of 1830 a former midwife, named Vogelsang, used to take the sections in hand. The renowned Pirogoff went through a course of pathological dissection and surgical operation under the guidance of this lady. Virchow soon gathered a circle of enthusiastic workers around him, on whom the juvenile teacher (he was only twenty five years old) exercised a mighty influence. Of the members of his first course who have later become known may be mentioned Alexander von Francius, teacher of zoology at Breslau (died 1877), Carl Hoffmann (died at Costa Rica), both distinguished *savants*, and Carl Pagenstecher. Certain events in the year 1847 led to an interruption of the lectures. Virchow took an active part in political life. It appeared to him the duty of a physician to support the efforts of the Liberal party. "The physician is the natural adviser of the poor," he wrote at that time. The managers of the Charité were offended at the democratic opinions of their prosector, and dismissed him from his post, in which, however, after a short time he was reinstated, but only with half the salary. Under such circumstances his appointment to Würzburg was very opportune, especially as he was engaged to the daughter of the gynæcologist, Carl Meyer. In May, 1856, he was recalled to Berlin, and the erection of a pathological laboratory was consented to, which Virchow had made a condition of his acceptance of the appointment; and which became a sort of shrine for aspiring medical students. A number of important works have issued from it. Many of Virchow's students and assistants became professors. Of the assistants may be mentioned Hoppe Seyler and Recklinghausen of Strasburg, Grohé, Baeter, and Grawitz of Griefswald, Kühne of Heidelberg, Klebs of Zurich, Cohnheim of Leipsic, and Ponfick of Breslau. But almost innumerable are the practical physicians who have gone forth from Virchow's school, who will never forget the shrewd conclusions and the clear expositions which distinguished the lectures of their eminent master.

Dr. Gaertner, formerly of the "Reichs Gesundheitsamt" in Berlin, has been appointed Professor of Hygiene at the University of Jena. He is known as the author of a paper on "Hygiene on Board Ship,"[1] also for experiments as to the best way of making use of the different antiseptic remedies in the treatment of wounds, on which subject he reported at last year's German Surgical Congress.

Dr. Loeffler has qualified as Privat Docent in Hygiene at the Berlin University. Dr. Loeffler has assisted in the investigations of Koch on the anthrax vaccination, which led later to a scientific feud between Drs. Koch and Pasteur. Dr. Loeffler has worked with Professor Schütz on the disease of glanders, which in 1882 led to the discovery of the specific bacillus. His works on Disinfection through Hot Water Steam and on Diphtheria in Human Beings and in Pigeons are also worth mentioning.

Berlin, May 16th.

DEATH OF A CENTENARIAN.—A woman named Craughwell died recently near Ballinrobe, at the advanced age of 107. Her health up to the day before her death was so good that she attended a funeral within a few hours of her decease. Married at seventeen to a soldier, she went through all the Peninsular wars, and later on was at the battle of Waterloo. She subsequently went to India and China, and returned to Ballinasloe a widow some [illegible] since. A correspondent of the *Cork Constitution*, from which these details are taken, states that on the day of her death he saw her knitting and sewing.

Obituary.

HENRY JACKSON, M.R.C.S.

THIS young, active, and genial member of our profession, whose death took place at Barnstaple on April 26th, passed his pupilage with Dr. Harper of that town, and entered the Middlesex Hospital, where he was characterised by his persevering industry, which won him several class distinctions. Having qualified as M.R.C.S. and L.S.A., and held the resident post of obstetric officer, he returned to Barnstaple as partner with Dr. Harper in 1873. At the time of his death he was one of the surgeons at the North Devon Infirmary and consulting surgeon to the North Devon Dispensary; he was also medical officer and public vaccinator for the second and fourth districts of the Barnstaple Union, and medical officer of health for the Barnstaple Urban and Rural Sanitary Authority. In 1882 he married the only daughter of James Bilney, Esq., of Barnstaple, whom he leaves a widow with three children. The universal respect and goodwill entertained towards him, and the great sympathy felt for his relatives, were evidenced by the very large number of persons who followed him to his grave, and by the still larger concourse which lined the road to the cemetery. In the procession, besides relatives and friends from far and near, were the borough police, one hundred and thirty Oddfellows and Rechabites, a deputation from the North Devon Benevolent Society, all the medical men of the town without exception, the mayor and corporation, and representatives of the various borough institutions with which the deceased was connected, besides a goodly number of patients to whom he had endeared himself by his genuine kindness and professional skill. From one of the local papers we may cull a paragraph, as showing that the public are not wanting in appreciation of the work of the profession, which enables one even at an early age—Mr. Jackson was only thirty-five—to win a very large measure of esteem and goodwill. The *North Devon Herald* writes: "To very considerable attainments Mr. Jackson added infinite painstaking, much industry, and patient attention. His cheery presence, ready sympathy, and unvarying patience were as grateful as his advice; and that his heart was in his work was patent from the energy, time, and thought he gave to it. In his public capacities he well merited the high reputation he possessed for conscientiousness and hard work. As medical officer of health, he rendered valuable and devoted service in improving the sanitary condition of the locality. As one of the medical officers of the union, he was popular with the poor, and although they are singularly prone to grumbling, complaints from them were seldom, if ever, heard. All the more sorrow and regret are accordingly felt that so much steady application and exemplary zeal have been lost by his untimely removal. His illness only lasted some three weeks, and he succumbed to a complication of rheumatic fever, pleurisy, and heart affection."

PROF. LUIGI PAGANUCCI.

THE Tuscan School lost on the 13th inst. an able representative in Luigi Paganucci. He was born at Montalaterone, in the province of Siena, on July 8th, 1808, and devoted himself in the neighbouring seat of learning to the study of the medical sciences. He became especially accomplished in anatomy, on which he wrote a treatise ("Dell' Anatomia Umana"), which long held its ground, and was appointed Professor of the Science in 1850 at the R. Arcispedale di S. Maria Nuova in Florence. The chair, being a supplementary one, was suppressed in 1867, and three years later Prof. Paganucci had put himself on the retired list till, on March 10th, 1873, he was recalled from a by no means inactive seclusion to the Professorship of Descriptive Anatomy in the Istituto di Studi Superiori. In 1874 he assumed the post of superintendent of the Physiological Museum, and also became lecturer on Pictorial Anatomy to the students in the Fine Arts Academy.

His solidly grounded reputation for learning and teaching power was acknowledged not merely in Italy, but throughout Europe, by numerous scientific associations, of which he became active or honorary fellow—such as the Medico-Physical Academy of Florence, the Academies of the Fine Arts in Florence and Perugia, the Physio-Critical Academy of Siena, and many others. Among his published writings, besides the treatise on Human Anatomy already mentioned, may be enumerated "Della Matrice e delle sue Appartenenze nei differenti Periodi della Vita Muliebre, fuori del Tempo della Concezione" ("On the Matrix and its Appurtenances in the several Periods of Woman's Life, apart from the Time of Conception"); "Biography of Professor Tabarran"; "Parere interno all' Individualità dei due Scheletri trovati nel Mausoleo scolpito da Michel Angiolo, e che sta a sinistra di chi entra nella celebre Cappella della Basilica di S. Lorenzo" ("Opinion on the Personality of the Two Skeletons found in the Mausoleum sculptured by Michel Angelo, and standing on the left hand as you enter the celebrated Basilica of San Lorenzo")—a very ingenious tractate; and many contributions to the transactions and periodical literature of the profession.

"His loss," says a Tuscan contemporary, "will be poignantly felt wherever science and its votaries are held in honour. In Florence especially, where he had a wide circle of colleagues, pupils, friends, and admirers, the announcement will be received with a sense of almost personal bereavement."

DR. WILLIAM PATTULLO.

(OF REWA, FIJI.)

THE news of the death (said to be due to acute dysentery) of this accomplished young medical practitioner—only three years after he had accepted, along with Dr. Beith, an appointment in our latest colony—will cause much sorrow among his friends. In alluding to this sad event, Professor Gairdner recently addressed to his class a few words, to the effect that, although the majority of those present could scarcely have known personally how much Dr. Pattullo was beloved and esteemed by all his teachers, he might be allowed to claim for those who could join with him in this tribute the sincere desire to give expression to their sympathy with Dr. Pattullo's sorrowing relatives, their regard for his memory, and their appreciation of his manifold virtues. A "son of the manse," added Dr. Gairdner, "and one of the best of the many good ones I have known as their teacher, he passed through his career as an undergraduate not only with distinction, but with brilliant success, and his bright and sympathetic character made the promise of his future in that far-off home, in one of the finest climates in the world, almost a matter to be rejoiced in as if it were already sure. About a year ago he came home, married, and returned to his post, and now we have the news of his premature death from a disease of which I only know as yet that it seemed to Dr. Beith to require the transfusion of blood from his own veins into those of his companion—a disease, therefore, probably acute, and certainly attended by extreme prostration. We can only now offer this tribute of our sympathy to the young wife whom he has left alone in the world, and to the parents who watched his infancy and his manhood alike with high hopes of his future success and reputation in his profession."

MEDICAL DEFENCE UNION.—On the 6th inst. nearly a hundred members of the profession met at the Birmingham Medical Institute to consider the desirability of forming a Midland Branch of the above Union. Mr. Lawson Tait occupied the chair, and stated, as showing the imperative need for co-operative action in our profession, that he himself, during the last twenty years, had actively assisted in the defence of twenty-one cases in which criminal charges or civil actions had been brought against medical men, in every one of which the charge had broken down. In most of these cases, had it not been for the spirited action of medical brethren, financial and social ruin would have resulted to the defendants. It was resolved to form a Midland Branch of the Medical Defence Union, and about sixty at once joined in the room. At a subsequent meeting, a local committee was formed for the management of the affairs of the Branch. Mr. Lawson Tait was elected president, and Dr. Leslie Phillips of Birmingham and Mr. F. S. Goulder of Dudley hon. secretaries; from these gentlemen any information may be obtained.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Notices respecting the election to the Council, for which there are four vacancies, were issued on Friday to every Fellow whose address is known to the Secretary, and the usual advertisement appeared on that date in the *London Gazette* and two daily newspapers, as required by Section 4 of the Bye-Laws. Fellows desirous of becoming candidates for re-election must apply to the Secretary for the necessary papers, which must, when duly filled up, be deposited with him *not later than Monday, June 7th next* We understand that two of the retiring members of Council will be candidates for re-election. The election will take place on Thursday, July 1st.

The following gentlemen, having previously passed the required examinations, were at the last meeting of the Council admitted Fellows and received their diplomas:—

Charles Wray, Long Marston; Membership dated Nov. 18th, 1881.
Harry Littlewood, Hempstead; April 17th, 1883.

At the same meeting the following gentlemen were elected Fellows as Members of twenty years' standing:—

George Yeoman Heath, Newcastle-on-Tyne; Membership dated May 17th, 1843.
Henry Cayley, Calcutta; December 21st, 1855.

Eighty-eight candidates presented themselves for the Primary Examination in Anatomy and Physiology on the 20th, 21st, 24th, 25th, and 26th inst., of whom 47 passed and 41 were referred.

ROYAL UNIVERSITY OF IRELAND.—The following have passed the examinations in Medicine and Surgery:—

BACHELOR OF MEDICINE.—Upper Pass: *Cornelius Bradley, *James Bradley, George Browne, James Chambers, *James Donelan, *George Freud, R. B. Gorsuch, *John L. Livingston, *Robert W. Nixon, Richard H. Wagner.—Pass: J. J. Attridge, W. F. Browne, J. K. Close, E. Curtin, S. H. Dunlop, G. F. Ewens, E. B. Hazleton, G. A. Junk, T. B. Kane, L. Lyttle, W. E. MacFeeters, W. Milligan, W. N. Murphy, A. T. Nash, J. O'Connor, C. O'Neill, W. J. Richardson, M. J. Robinson, J. T. Shaw, A. E. Thompson, J. J. Tobin, F. E. Townsend, G. R. Young.

* These candidates may present themselves for the Honour Examination.

MASTER OF SURGERY.—Cornelius Bradley, James Bradley, James Chambers, J. K. Close, Eugene Curtin, James Donelan, S. H. Dunlop, J. F. Eagleton, Robert English, John Flynn, B. Forde, G. Freud, R. M. Griffin, M. H. Hannigan, Daniel Lee, J. Livingston, W. E. MacFeeters, John Menary, S. Moore, W. U. Murphy, R. Nixon, John Oliver, C. O'Neill, W. R. Orr, W. Richardson, A. S. Thompson, A. E. Thomson, F. Townsend, R. H. Wagner, G. R. Young.

A meeting of Convocation of the University will be held on July 27th, to elect two members of the Senate in the vacancies caused by the death of Archbishop Trench and the expiration of Dr. Curtis's term of office.

COLLEGE OF PHYSICIANS IN IRELAND.—At the May examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Rodney Harrison Abbott, Arthur Badcock, Louis Birch, Guy Stewart L'Estrange, J. Watson Lonsdale, Daniel McCann, Francis Waldron McCanley, Elrington Simon Tuckay, Barcroft Carroll Manly, Walter John Reed, John Joseph Savage, Patrick Joseph Sheridan, William Edward Waters.

MIDWIFERY.—John H. Griffin, Guy Stewart L'Estrange, James Watson Lonsdale, Barcroft Carroll Manly, John Joseph O'Brien, Patrick Joseph Sheridan, William Edward Waters.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The undermentioned has been admitted a Fellow of the College:—

George Edward Twiss, Army Medical Staff.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 20th inst.:—

Hooper, Ebenezer, Kingston, Ontario.
Smith, Henry Craven, Cravensea, Cockington, Torquay.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The quarterly meeting of the Medico-Psychological Association was held at Bethlem Hospital on May 19th, at 4 P.M. In the absence of the President, Dr. Eames, the chair was taken by Dr. Rayner. The following papers were read:—By Dr. Savage, on a case of "Insanity cured by removal of the Beard in a Woman"; by Dr. Percy Smith, on a case of "Ovariotomy in an Insane Patient"; and by Dr. Bower, on "Suicide and the Lunacy Laws Agitation." It was announced that the annual meeting would be held on August 9th.

DR. MATTHEW HINCHLIFFE has been placed on the Commission of the Peace for the borough of Dewsbury.

FOUR CHILDREN AT A BIRTH.—Mrs. Lars Grindahl, of Chetek, Eau, Claire County, recently gave birth to four children, all boys, who are doing well.

ON the 22nd inst. a boy was rescued from drowning at Chester by the gallant conduct of Mr. Hamilton, a local surgeon.

DR. COURY, of Kilkelly, has sent to M. Pasteur the first Irish patient, a man who was bitten by a rabid dog on the 11th inst.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—H.R.H. the Princess of Wales has fixed Friday, June 25th, at 1 P.M., for opening the new wing of the above hospital.

A BAZAAR in aid of the funds of the Great Northern Central Hospital will be opened at the Knightsbridge Barracks by H.R.H. the Princess Christian on the 31st inst.

THE anniversary banquet on behalf of the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, has been postponed.

PRESENTATION.—The nurses of the Bradford Infirmary have presented Mr. W. J. Spence, the house-surgeon, who is leaving that institution, with a handsome walnut writing cabinet, bearing a suitable inscription.

MANSLAUGHTER BY A LUNATIC.—One of the inmates of the Richmond Lunatic Asylum, Dublin, was killed last week by another lunatic, who fractured his skull. The culprit will be sent to Dundrum Criminal Lunatic Asylum.

GUY'S HOSPITAL.—The Biennial Dinner will be held at the Holborn Restaurant on Friday, June 2nd, Mr. Durham in the chair. H.R.H. the Duke of Cambridge will distribute the school prizes on the same afternoon.

AN inquest was held at Widnes, on the 24th inst., on the body of a man who died two days previously from taking an overdose of laudanum. Although directed to take from ten to fifteen drops, the deceased took forty. A verdict of "Death from misadventure" was returned.

THE members of the Royal Commission on the Condition of the Blind, the Deaf and Dumb, &c., have left England for the purpose of inspecting the institutions for the blind and for deaf-mutes in Paris and the neighbourhood, and the systems of education there pursued.

THE LATE MR. KILGARRIFF.—This gentleman, whose death was referred to in our last issue, left his family unprovided for, and a meeting of friends interested in their welfare took place last week. The meeting was largely attended, and a sum of £200 was promised by those present.

GREAT NORTHERN CENTRAL HOSPITAL.—On Monday next, at 12 o'clock noon, Princess Christian of Schleswig-Holstein has consented to open the grand bazaar to be held at the Riding School, Knightsbridge Barracks, on the above day and June 1st and 2nd, in aid of the new buildings to be erected in the Holloway-road.

ANTHROPOLOGICAL INSTITUTE.—In connexion with the Institute conferences on the Races of the British Empire will be held on several days in the months of June and July, in the Conference Hall of the Colonial and Indian Exhibition. The first of the series will take place on June 1st, at 4 P.M., the subject being the Races of Africa.

WOLVERHAMPTON EYE INFIRMARY.—The committee of this institution have secured a suitable site of land, on the confines of the borough, on which to erect a new building, and a supporter of the charity has promised to erect an infirmary for in-patients, at a cost of £4000, provided that another building in connexion with it be constructed for out-patients, with consulting-room, waiting-room, and dispensary; and also that a sum of £2500 be subscribed as an endowment fund. It is estimated that altogether a total of about £8000 will be required to enable the committee to accept the offer made to them. The operations of the charity are at present carried on in a rented house much too small for the accommodation of the increasing number of patients.

Digitized by Google

CASE OF CATALEPSY IN CORK UNION WORKHOUSE.—There is at present in one of the male wards of the Cork workhouse a man named O'Sullivan, aged fifty years of age, who for over twelve months—viz., April 27th, 1885—has been in a deep sleep except when awakened to partake of food. On the date above mentioned he was found by the constabulary fast asleep in the open air, and removed to the workhouse. When shaken roughly, he awakes and will do what he is told, and when food is placed before him he will take it, but he has to be shaken at intervals to prevent him going to sleep. When he has finished eating, he falls asleep in whatever posture he happens to be in at the time; if put in a standing position with his hands above his head, he remains in that posture until disturbed; and if placed on two chairs, his head resting on one and his feet on the other, he remains so, the body being quite stiff.

THE LATE DR. THOMPSON.—At the meeting of the Council of the Irish Medical Schools and Graduates' Association, held on the 19th inst., the following resolution was passed, on the proposal of the Chairman of Council (Professor Gerald F. Yeo, M.D.), seconded by Dr. Macnaughton Jones (President)—viz.: "That the Council of the Irish Medical Schools' and Graduates' Association, having regard to the late Dr. Thompson's intimate connexion with the Association, first as its founder and honorary secretary, and afterwards as honorary treasurer, hereby desires to convey to Mrs. Thompson its deep sympathy with her in her bereavement, and to express its sense of the loss the Association has sustained by the death of one to whom it has been so much indebted." Brigade-Surgeon W. Alexander, M.D., has been appointed honorary treasurer to the Association.

UNIVERSITY OF OXFORD.—Notices have been issued that examinations for the degree of Bachelor of Medicine will commence in the Medical Department of the Museum as follows:—The Second (or Final) Examination, Thursday, June 17th, at 10 A.M. The First (or Scientific) Examination, Saturday, July 3rd, at 10 A.M., for Chemistry and Physics; and on Monday, July 5th, for Anatomy and Physiology. Candidates for either of these examinations should send in their names on or before June 3rd to "the Regius Professor of Medicine, Medical Department, Museum, Oxford." Candidates for the Scientific Examination are to state whether they have passed the Preliminary Honour Examination in the School of Natural Science; and, if not, whether they desire to present themselves for Physics and Chemistry only at this examination, or for all the subjects thereof. Both the examinations will be conducted this year under the conditions of the statute of 1860.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BOND, J. W., M.D., B.Sc.Lond., M.R.C.S., has been elected a Member of the Honorary Staff of the Hospital for Diseases of the Throat, Golden-square.

BROCKATT, A. A., L.R.C.P., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

BROWNE, OSWALD A., M.A., M.B., M.R.C.S., &c., has been appointed Physician to the Royal Hospital for Diseases of the Chest, City-road, London.

COLLIER, M. P. MAYO, M.S.Lond., F.R.C.S., Senior Assistant Surgeon, has been appointed to have charge of the Throat and Ear Department at the North-West London Hospital, Kentish Town-road.

CROWDY, F. D., M.B.Oxon., M.R.C.S., L.S.A., has been appointed Resident House-Physician to St. Thomas's Hospital.

EVANS, C. S., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

GODFREY, A. E., L.R.C.P., M.R.C.S., has been appointed Non-resident House-Physician to St. Thomas's Hospital.

GOODDY, E. S., M.R.C.S., L.S.A., has been appointed House-Surgeon to St. Thomas's Hospital.

HUTTON, J. S., L.R.C.P., M.R.C.S., L.S.A., has been appointed Resident Accoucheur to St. Thomas's Hospital.

KIDD, H. CAMERON, L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

LITTLE, WM. MAXWELL, M.B., C.M.Edin., has been appointed Junior Assistant Medical Officer to the Norfolk County Asylum, Thorpe, near Norwich.

MACDONALD, G., M.D., M.R.C.S., has been elected a Member of the Honorary Staff of the Hospital for Diseases of the Throat, Golden-square.

MONTAGUE, A. J. H., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

NAIRN, R., M.R.C.S., has been appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

NICKOL, F. C., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

PARSONS, F. G., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

PRINGLE, JOHN J., M.B., M.R.C.P., &c., has been appointed Physician to the Royal Hospital for Diseases of the Chest, City-road, London.

SHAW, JOHN, M.D.Lond., M.R.C.P., Senior Assistant Physician, has been appointed to have charge of the Gynæcological Department at the North-West London Hospital, Kentish Town-road.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

TOBIN, MR., Assistant Surgeon, St. Vincent's Hospital, Dublin, has been appointed Surgeon to that institution.

TRAVERS, OTHO ROBERT, M.R.C.S., L.S.A., has been appointed Medical Officer for the Seventh District of the Battle Union.

WALFORD, EDWARD, M.D., S.Sc.C.Camb., has been reappointed Medical Officer of Health for the Urban Sanitary District of Ramsgate, for a term of three years.

WHITE, WILLIAM HENRY, M.A., M.D., M.R.C.P., &c., has been appointed Physician to the Royal Hospital for Diseases of the Chest, City-road, London.

WOLFENDEN, R. N., M.D., has been elected a Member of the Honorary Staff of the Hospital for Diseases of the Throat, Golden-square.

Births, Marriages, and Deaths.

BIRTHS.

BELEMORE.—On the 15th inst., at Lyndhurst, Eaton, Norwich, the wife of Brigade-Surgeon A. J. Belemore, of a son.

COOMBS.—On the 19th inst., at Redburn, Spring-grove, St. Cuthbert's, Bedford, the wife of Rowland H. Coombs, M.D., of a daughter.

CRAIG.—On the 11th inst., at Sawtry, Petertow, the wife of James Craig, M.D., of Eastwood, Notts, of a son.

MOODIE.—On the 21st inst., at Park-avenue House, Stirling, the wife of Robert Moodie, M.D., B.Sc.Ed., of a daughter.

MORTIMER.—On the 15th inst., at Haslar Hospital, Gosport, the wife of Deputy Inspector-General E. T. Mortimer, R.N., of a daughter.

PERIGAL.—On the 23rd inst., at New Barnet, Herts, the wife of Arthur Perigal, M.D., of a daughter.

WARNER.—On the 18th inst., at Rydal, Woodford-green, Essex, the wife of Percy Warner, M.R.C.S., L.R.C.P.Lond., of a son.

WELSFORD.—On the 21st inst., at 46, Oxford-gardens, W., the wife of George F. Welsford, M.B., of Woodstock, Oxon, of a son.

MARRIAGES.

CLEGHORN—BROWNING.—On the 1st ult., at the Church of the Nativity, Blenheim, New Zealand, George Cleghorn, M.R.C.S., to Annie, daughter of the late James Torry Browning, of Oxford.

MENDS—WILSON.—On the 20th inst., at St. James's, Kidbrook, Bowen Stilon Mends, Surgeon, Royal Navy, to Ada Latham, elder daughter of Colonel John J. Wilson, Royal Engineers.

OMAN—DARRACOTT.—On the 14th ult., at Holy Trinity Church, Sliema, Malta, N. Oman, M.D., to Rosie, youngest daughter of the late Thomas Bligh Darracott, Esq., of Kingsbridge, Devon, and Trinidad, W.I.

PIGGOTT — LAWRENCE. — On the 20th inst., at St. Mary Abbot's, Kensington, Fred. Cecil Holman Piggott, B.A.Cantab., M.R.C.S., &c., of Richmond and Teignmouth, to Ada Maria, daughter of the late Henry and Ellen Lawrence, of Kensington.

SCOTT—HEWETT.—On the 22nd inst., at Batu Gajah, Kinta, Perak, William Duncan Scott, M.A.Oxon., M.B., C.M., of the Perak Government Service, to Alice Mary, second daughter of the late Thomas Douglas Hewett, of H.M.'s Indian Navy.

DEATHS.

CROFTON.—On the 23rd inst., at Carlton Lodge, Teignmouth, Devon, William Crofton, M.D., of Montagu Villa, Cheltenham, and of Lakefield, co. Leitrim, J.P. for that county, in his 73rd year.

JONES.—On the 22nd inst., at Henblas, Bala, Merionethshire, Richard Owen Jones, M.R.C.S., L.S.A., aged 48.

MACNAB. — On the 23rd inst., at Greenhill, Crosshills, Yorkshire, R. A. Macnab, M.D., aged 57.

TROTTER.—On the 21st inst., at Sunny Bank, Holmfirth, Edward Trotter, Surgeon, in the 76th year of his age. Friends will please accept this the only intimation.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE IMPERIAL UNIVERSITY OF JAPAN.

THE Imperial University of Japan has been recently reorganised. One of its most important departments is the College of Medicine, which is presided over by Dr. Miyake. The main course of instruction is modelled after that in the German medical colleges; the foreign professors, of whom there are at present five, are also German. The course covers a period of four years, and the preparatory course three years more. There is also a course of lectures delivered in the vernacular, which is called the special course. The total number of students last year was nine hundred and seventy-two. The medical school of Japan is eleven hundred years old. In its early days it was presided over by a superintendent and assistant, under whom there was one professor of medicine, one of acupuncture, one of massage, one of diseases of women, a teacher of materia medica, botanists, and a number of physicians. The whole course covered seven years.

Mr. R. Hodges is referred to a general notice at the head of this column.

RINGWORM IN NEW-BORN INFANTS.

To the Editor of THE LANCET.

SIR,—The two medical practitioners who have recorded in your pages the discovery of ringworm in new-born infants would confer a boon upon medical science by giving some further proof of the correctness of their diagnosis. It would, for example, be interesting to know whether the diagnosis was verified by the discovery of spores or mycelium under the microscope. Taking into consideration all that is at present known as to the conditions of intra-uterine human life on the one hand, and all that is known as to the natural history of tinea on the other, is it not on the whole more probable that the diagnosis of ringworm was a mistake than that two children were born with patches of fungoid growth on their skin?

I am, Sir, yours truly,

May 23rd, 1886. M.B. OXON.

Mr. C. Clark Burman (Belford) asks if intense cutaneous irritation has been noticed to follow the administration of hydrobromic acid.

PRACTICE IN CANADA.

To the Editor of THE LANCET.

SIR,—Could any of your readers give any information regarding practice in Canada—nature of appointments, and how procurable; if a special licence must be obtained, and fees?—I am, Sir, yours truly,

May 25th, 1886. COLONIST.

NEURASTHENIA AND ABDOMINAL BELTS.

THE inhabitants of this globe may suffer from nervous weakness or neurasthenia simply because they neglect to wear abdominal supports! At least that is the conclusion that naturally follows from the recent teaching of M. Glénard of Lyons, who believes that some cases of nervous exhaustion are attributable to gastroptosis, or lowering of the stomach; to hepatoptosis, or descent of the liver; or to nephroptosis, which is another name for floating kidney. Imagine the following colloquy in a physician's consulting-room:—Patient: "And now, doctor, after all this sounding and examination, pray tell what is the matter with me." Physician: "My dear sir, you have habitually bolted your meals, which have likewise been too abundant; as a consequence you have caused your stomach to descend from its natural situation—*facilis descensus Averni*,—and this gastroptosis, as we call it, has acted seriously on your nervous system, hence your languor, irritability, and general loss of tone, &c. My advice to you is to read 'Strapmore,' put on an abdominal belt, and cultivate a waist!"

Beeaas is bound not to practise without the consent of the principal.

A ROUGH-AND-READY MEDICAMENT.

To the Editor of THE LANCET.

SIR,—Having a strong impression that I once read in the "Mémoires de M. le Baron Larrey," or in some other autobiographical publication of that period, that he (Larrey) or one of his subordinates had resuscitated a quasi-moribund French general or marshal by wrapping him up, *pueris in naturalibus*, in a sheep or horse's skin that had been just stripped off the living beast, during the disastrous retreat from Moscow in 1812, I am anxious to know if such is the case, and if there is any evidence to show that this practice has existed from all historic time—not only among savage races, but also among primitive or remotely situated peoples in our own midst. I believe that such will, on due inquiry, be found to have been the case, and I ask your permission to allow me to solicit authentic deliverances on or references to the point in your pages. Having had some recollection of seeing it mentioned in Homer, I glanced yesterday, with Pope in one hand and the original itself in the other, over this classic, looking especially for any allusion to it under the headings of "Podaleirius" and "Machaon," but utterly failed in this search, and the only descriptions of it I can just now recall stands as follows. Relating a hypothetical case of small-pox—or, rather, dwelling on the peculiarities of its treatment as these are developed on the spot—Mr. Thorburn says, in his "Bannu," p. 115, that the father of our supposed sufferer "nursed him for a day or two, during which the fever showed no signs of abating, and *then determined to apply the great Pathan remedy, which is practised all over Afghanistan.* He had a sheep slaughtered and skinned, and after rubbing a little oil or turmeric upon the skin, wrapped up his son in it while it was hot. He next laid him on the bed, put a large quilt over him, and kept the door shut to prevent any draught coming in. At the end of twenty-four hours the skin was removed, and a new one substituted. This time it had the desired effect, and before Sherdil had worn it ten hours, he said in a faint voice to his father, 'Papa, I have become water.'" I will only here add that the italics are mine, and that the Cabulees I questioned on this issue at Peshawur appeared to be familiar with it. Anyhow, none of them denied its occasional use or efficacy in that country.

In that fragment of autobiography with which Mr. Lockhart begins his interesting Life of Scott (I allude to the Abridgment of it only), it is said that "it is here, at Sandy Knowe, in the residence of my paternal grandfather ..... that I have the first consciousness of existence. ..... Among the odd remedies recurred to, to aid my lameness, some one had recommended that so often as a sheep was killed for the use of the family, I should be stripped and swathed up in the skin, warm, as it was flayed from the carcass of the animal. In this Tartar-like habiliment I well remember lying upon the floor of the little parlour in the farm-house, while my grandfather, a venerable old man with white hair, used every incitement to make me try to crawl. I also distinctly remember the late Sir George McDougal ..... joining in the attempt. Kneeling on the ground before me, and dragging his watch along the carpet, he, too, tried to induce me to follow it." The stratagems or incitements of these two venerable personages are only, I think, an expression of the faith with which, at all ages and in every clime, the "movement" treatment, *alias* massage or shampooing, has been employed for the cure or relief of stiff or painful joints.

I am, Sir, your obedient servant,

Auriol-road, W., May 16th, 1886. WM. GUERRAN.

P.S.—Since the above was written I have looked for information on the point in the works of Gibbon, Pliny, Quintus Curtius, and Rollin, but can find nothing bearing on it in either of these writers, and the words of Curtius would seem to imply that the practice was unknown to the followers of Alexander. Anyhow, they did not resort to it even amid the snows and ice of the "frosty Caucasus"; and we are, I fear, no whit more advanced in our knowledge or treatment of the torpidity, &c., that are produced by extreme cold than they were. "A compluribus torpentes excitabantur," says our author, "neque aliud remedium erat, quam ut ingredi cogerentur"; and if friction, and the warm bath, were here thrown in—which may be, for all we know to the contrary, included in this "excitabantur"—I know of no other, or better, "remedium" for these conditions in these our own days.—W. C.

ALCOHOL IN POOR-LAW PRACTICE AT CAMBERWELL.

DR. GREENE having called for a return of the cost of wine and spirits issued on medical certificates for out-door relief in ten years, the returns show a diminishing quantity—thus: 1876, £67; 1877, £44; 1878, £45; 1879, £22; 1880, £25; 1881, £35; 1882, £30; 1883, £25; 1884, £22; 1885, £16. It would seem that in pauper, as in private, practice the tendency is to a diminishing quantity of alcohol. The profession, however, will not entirely abandon the right to use alcohol when it sees fit, in spite of the startling statement of the chairman of the board that alcohol had only been used in three cases at the London Temperance Hospital since it was opened, and that all three cases proved fatal.

Messrs. Davis, Bergendahl, and Co.—We have no recollection of the article.

MECHANISM OF DEFECATION, MICTURITION, AND PARTURITION.

To the Editor of THE LANCET.

SIR,—In your issue of May 15th I am reported to have said, at the Obstetrical Society's last meeting, "that in defecation, micturition, and parturition there is a reflex tonic contraction kept up in the muscular fibres, especially in the sphincters." As this is not what I said, and conveys a wrong impression of what I meant, I should be glad if you would insert this correction. What I said was that the sphincter ani (externus) and sphincter vesicæ (Henle), and probably the cervix uteri (=sphincter uteri), were ordinarily in a state of reflex tonic contraction, and that during the acts of defecation, micturition, and parturition these three sphincters were respectively relaxed. Not that the muscles actively dilate, but that they passively relax, so that the different expulsive muscles have less resistance to overcome than they would have if the reflex tonic contraction were kept up in the sphincters.

I am, Sir, yours truly,

St. Thomas's-street, S.E., May 24th, 1886. P. HORROCKS.

UNQUALIFIED ASSISTANTS.

One who has Served his Time as a Pupil.—There is nothing in the Medical Bill of the Government to alter the law as regards unqualified practice or bearing on unqualified assistants. Our correspondent's position is one to which little objection has been raised, and is very different from that of an unqualified assistant placed by a qualified practitioner in charge of a so-called dispensary, or in sole charge of patients. A private Bill before Parliament, introduced by Mr. Morgan Howard and others, aims a direct blow at the latter class of cases, and with much justification. The drift of professional and public opinion is in the direction of having all assistants qualified.

Inquirer.—A copy of the Russian pamphlet will be forwarded to our correspondent.

Fairplay.—The matter is more of local than of general interest.

THE STRENGTH OF THE SOLUTIONS OF MORPHIA AND STRYCHNINE.

To the Editor of THE LANCET.

SIR,—I have just purchased the latest edition of "Squire's Companion," and am a little surprised to find that the solutions of morphia and strychnine have been increased in strength. Ought not the medical profession to have been warned that such was the case? for many might prescribe those forms in entire want of knowledge that these alterations had been made.

I am, Sir, yours truly,

May 24th, 1886. IMPRUDENS.

A SCIENTIFIC ADDRESS A HIGHLY PRIVILEGED COMMUNICATION.

IN a case occurring in Pennsylvania before Judge Arnold, in which a Dr. Carl Seller was sued for speaking disparagingly of a proprietary medicine—not to the public, but in the course of an address delivered to the College of Pharmacy—the judge, after hearing the plaintiff's case, directed the jury to bring in a verdict for the defendant. In his charge, the law of the State was declared to be that a scientific lecture before students or a medical association is not only a privileged, but a highly privileged, communication, and that malice must be shown to exist in order to render the lecturer liable for an expression of opinion under such circumstances.

Junior.—Fees received by assistants for any purpose are the property of the principal. But such fees as are mentioned by our correspondent may fairly be shared with his assistant, if the principal sees fit.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—In my observations on Mr. Eve's specimens exhibited at the Pathological Society (THE LANCET, May 22nd, p. 973) I referred not to "Harz's paper on General Anatomy" as reported, but to Harz's monograph published about two years since in the German *Archiv für Mikroskopische Anatomie.*

I am, Sir, yours truly,

Granville-place, W., May 21st, 1886. ALBAN DORAN

THE MEDICAL BILL AND PARIS DEGREES.

A Graduate of Paris.—There can be no doubt that the degree of Paris would be immediately and cheerfully recognised as entitled to registration by the Medical Council under the Bill of the Government should it become law. It is not specified, nor is any foreign or colonial degree; but it is eminently one of the degrees the registration of which is contemplated.

Justitia will find an allusion to the subject in an answer to another correspondent. Unqualified assistants have often themselves to blame for the criticism they incur by placing themselves in thoroughly false positions.

Mr. Buckingham.—We are not in possession of the information.

USE OF ICE FOR DYSPNŒA.

To the Editor of THE LANCET.

SIR,—In a case of advanced phthisis which came under my care recently, and in which acute attacks of dyspnœa, accompanied with, and apparently produced by, a febrile condition of the patient, proved the most troublesome and distressing symptom, I found that ice used locally on wrists and temples, with due regard to the state of the pulse, &c., afforded very great relief, the patient being soothed, the breathing relieved, and sleep obtained. Doubtless the lowering of temperature thus produced tended to check the excessive tissue waste, and in this way threw less work on the defective lungs.

Although I do not remember to have seen this treatment recommended in such text-books as I am familiar with, I venture to bring it to your notice, not as a startling novelty—since, if my explanation be the correct one, it is merely the bringing into play of well-recognised physiological principles,—but rather to elicit, it may be, some further illustrations of its beneficial employment, or some more experienced expression of opinion as to its applicability in cases where similar conditions exist.

I am, Sir, yours obedient servant,

May 25th, 1886. RANKINE DAWSON, M.A., M.D., &c.

A DAY IN THE COUNTRY.

THE REV. J. W. PITCHFORD, of St. Jude's Vicarage, Southwark, asks us to state that he will thankfully receive subscriptions towards a fund for enabling 400 school-children and others who have saved up their pence for the purpose, to enjoy a day's outing in the country.

Mr. Thos. Williams.—It is not incumbent upon a doctor to expose all the latent and possible diseases of his patients, though he is well within his duty in giving them such general hints as are likely to preserve their health.

DIET FOR GOUTY SUBJECTS.

To the Editor of THE LANCET.

SIR,—Will any of your numerous readers suggest the most wholesome diet for a medical brother who is a martyr to gout, with a ravenous appetite and a tendency to corpulency. He has tried "Banting," with an increase of the former evil, and a vegetarian diet with an increase of the latter. Any suggestion will be gladly received.

I am, Sir, yours faithfully,

May 17th, 1886. A SUBSCRIBER.

Medicus (Orange State) and *M.D.* (Mossley) have forgotten to enclose their cards.

ERRATA.—In our last issue, page 980, second column, third line, for "lymph" read *lymphatics.*—At page 995, first column, last line of Extraordinary Cæsarean Operation, for "woman" read *wound.*—In Mr. Leeming's letter on Amnesic Aphasia, published in our last, for "use common words" read *uncommon* words.

Medical Diary for the ensuing Week.

Monday, May 31.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 3 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Dr. Leonard C. Wooldridge: On the Pathology of the Blood.

Tuesday, June 1.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee The Function of Circulation.

Wednesday, June 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Dr. Leonard C. Wooldridge: On the Pathology of the Blood.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. John Phillips and others. Dr. Champneys: On the Artificial Production of the so-called Lymphatic Varix.—Dr. Herman: Note on one of the Causes of Difficulty in Version, with remarks on the Practice of Amputating the Procident Arm.—Dr. John Phillips: Four cases of Spurious Hermaphroditism in one Family.

Thursday, June 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Professor Alexander Macalister: Habit as a Factor in Human Morphology.

Friday, June 4.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Dr. Leonard C. Wooldridge: On the Pathology of the Blood.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Dr. Walter H. Gaskell: The Sympathetic Nervous System.

Saturday, June 5.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. G. G. Stokes: Light, with special reference to Effects resulting from its Action on Various Substances.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

Ingleby Lectures
ON
SOME FUNCTIONAL DISORDERS OF FEMALES.

By WILLOUGHBY F. WADE, F.R.C.P.,
SENIOR PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

THE late Dr. Ingleby was highly reputed in this town and district as a practitioner of the obstetric art. He was further known to the wider circle of professional students as a lucid and successful author. His representatives in 1876 resolved to devote a considerable sum of money to objects which might be serviceable to the poor whom he had so well served, and useful to the profession of which he had been so distinguished a member. Amongst these objects was the endowment of a lectureship for the delivery, annually, of lectures upon some subject connected with that branch of our art which he had loved and adorned. By the favour of the Council of the Queen's College, in whose hands the appointment is vested, I have the high honour of appearing before you to day as the Ingleby Lecturer for the year 1885.

LECTURE I.

The most unequivocal differences between the two sexes are unquestionably anatomical ones—the possession by each of organs of which the other is devoid. These organs are those which are directly concerned in the process of reproduction. This fact suggests that we have here the central point of the human race, that round which all revolves, from which all radiates. But, when we reflect, we perceive that in this fundamental respect we resemble not only all the animal but also the vegetable world.

It is not, then, so much the centre which differentiates us from the rest of the organic world—the same *leitmotif* governs the conjugation of the humble algæ and the gorgeous ceremonies of imperial nuptials. That *motif* is the impregnation of the passive by the active particle in obedience to the imperious obligation of Nature,—

> "So careful of the type she seems,
> So careless of the single life."

True, the radiations, the surroundings, the accidental accessories as distinguished from the essential elements, do place between us and the highest other grades an immense, and between us and the lowest an immeasurable, gulf.

But throughout the whole web of organic Nature one thread is never broken. Upon a common fabric the artificer may broider rude patterns in coarse materials or elaborate and complex designs in fine silk and gold thread strung with pearls and studded with precious stones. The canvas back is the law of reproduction; the rude design and sordid worsted are the conditions under which in the lower worlds this law is operative; the costly and artistic surface represents the grades of civilisation, up to the highest yet reached, which cluster round the same law in the human race. The splendid and fatal Queen of Egypt was fain to confess herself—

> "No more, but e'en a woman; and commanded
> By such poor passion as the maid that milks,
> And does the meanest chares."

Without a just appreciation, much less common than it ought to be—without a minute analysis of the subtle phases of thought and feeling, whose effects pervade the whole female organism, it is impossible to comprehend many of the cases we ordinarily meet with. Still more is it impossible to advise with wisdom in the rarer but still not infrequent cases, where upon our judgment and discretion hang, perhaps, the lasting happiness or misery of two lives. Only an inane prudery, then, can refuse to enter into a free examination of the relations of this law to "those delicate vessels in which are borne onward through the ages the treasures of human affection."

The reproductive cycle can, and indeed for the purpose of study must, be divided into stages. The time at our disposal would not suffice for even a superficial glance at each of these. I purpose, therefore, to confine myself to one, the first or preliminary stage, meaning thereby the transition of the girl into the nubile woman, and the nubile condition up to the time of marriage, which is the conclusion of the first stage. It must be borne in mind that classification is beset by difficulties from which there is no escape. Nature may be said to delight in curves; classification, on the contrary, rejoices in straight lines. "How can two walk together except they be agreed?" Nature refuses to agree to delimitation of territory, or to submit to a scientific frontier. It is as impossible to square the circle of Nature as it is that of the geometer. We shall therefore find that much which we have to consider does not exclusively appertain to this "preliminary stage." Though the circumstances and conditions of the ante-nuptial period conduce in an eminent degree to the development of certain disorders, yet these are seated deep down in woman's nature and constitution, and therefore the tendency to them is never eradicated.

The mother, within certain limits, the most subtle of observers, the nurse, informed with maternal instinct, will often point out psychical differences between the male and the female infant; it may be that such are perceptible even to the duller vision of man.

In childhood, the yearning of the girl for her doll, and of the boy for ruder diversion, presage still more clearly the subsequent divergence of the paths of each. The submission of the girl to the brother's will, her admiration and respect for his greater physical power, her general acknowledgment of his superiority, are not the outcome of an artificial state of society, but the mark of the differences of organisation which Nature has conferred, in order that each may hereafter be in accord with her reproductive laws.

With the advent of puberty, the psychical differences previously foreshadowed become clear and distinct, and there are also added physical differences, which it is unnecessary to specify. The establishment of puberty in the female is, as we know, often not unattended with derangements of the physiological equilibrium. Mothers too often are uneasy at what they consider undue retardation of the special feature of puberty, and this is a matter upon which, as you know, our advice is often sought. These cases may be usefully divided into four categories—namely: (1) Well-developed, strong, healthy girls; (2) girls in other respects healthy and strong, but of backward development; (3) well-developed but more or less unhealthy girls; (4) ill-developed and more or less unhealthy girls.

Before referring more in detail to these cases, let me offer a few words on the menstrual function generally.

We know that much has been written on the differences between the catamenial secretion and blood. That the distinctions made are just from a chemical point of view I am willing to admit. But I none the less firmly maintain that, from a clinical point of view, this discharge is a veritable hæmorrhage, and that this is a cardinal fact which can never with safety be overlooked in practice. That there are cases of menorrhagia which, no one would dispute, are to be regarded as hæmorrhages I assume. And who, I would ask, is prepared to fix the boundary which separates these from ordinary, or even from what are reckoned as insufficient, catamenia? What, then, are the systemic effects of loss of blood? These depend upon the quantity lost, the frequency of repetition, the state of the individual at the time, and no doubt to some, possibly to a large, extent upon idiosyncrasy. The effect of repeated losses depends, further, on the activity of the blood-making organs, and their power to restore the hæmatic equilibrium. It is consistent with our knowledge of these effects, as derived from examples both of spontaneous and artificial hæmorrhages, that the loss of a few ounces of blood should be a matter of indifference to a healthy person whose blood-producing apparatus was normally active. It is therefore quite comprehensible that an average catamenial evacuation, reckoned at about 5 oz., should not produce any very sensible effect on healthy women. On the other hand, in persons already the subjects of anæmia, whether that be due to spontaneous hæmorrhage, to artificial hæmorrhage, or to some more recondite cause, the effect of further loss of blood, in quantity even less than that of an average menstruation, is often to produce very distinct effects. Without going into details, it may be said that the new hæmorrhage removes the symptoms which had resulted from previous hæmorrhages. This may happen time after time, but with a difference. The difference being, that each time the period of relief is of shorter duration; that is, the symptoms return sooner, and probably with an increased intensity. Ultimately, a time comes when the hæmorrhage

Digitized by Google

ceases to be followed by any relief, or if by any, it is so slight and so transient as to be difficult of discernment.

Now I affirm, after very numerous inquiries extending over many years, that the effect upon an anæmic girl of an ordinary catamenial loss is strictly analogous to other hæmorrhages upon similar subjects. There are two standards by which the amount of loss may be adjudged to be normal or abnormal. One is by comparing it with the average loss of women. The other, and the more important, is by comparing it with the usual loss of the individual herself. But I go further, and say that an evacuation subnormal in amount, by whichever standard it is measured, is capable, under certain circumstances of not rare occurrence, of producing similar effects. This is the case even when, in addition to being subnormal in amount, the loss is subnormal in colour. The accuracy of these observations may readily be tested by each one of you for himself. But the critic must be familiar with the effects of repeated loss of blood, even in small quantities. He must further be prepared to make a minute and exact inquiry into the clinical history of his patient. And, lastly, he must enter into the investigation with an unbiased mind, not prepossessed with the idea that because the periods are apparently normal, or even deficient in quantity or colour, it is impossible for them to produce the effects of a hæmorrhage.

But it may be said, granting the accuracy of my observations, do they prove that the anæmia of girls is due to the repeated loss of blood by the catamenia? To this I would answer, in the first place, medical authorities are not agreed to offer us any other, or rather they are agreed to offer us none, and to say that none is known. In the second place, I would ask you this question: If you met with a case of anæmia, in which there was habitual loss of blood by hæmorrhoids, by epistaxis, by hæmorrhage from any other mucous membrane, would you refuse, because the loss was comparatively small, to admit that it was the cause of anæmia, and to base your treatment upon that view? To carry, not my argument, but my statement, a little further, I may add that cases are not unfrequent in which the first period produces anæmia. And on this point let me mention a very frequent source of fallacy. A mother, when she brings her child to us under these circumstances, very often says that she does so because she has never been regular. Whereas, in a considerable number of instances minute inquiry will elicit the fact that there has been one, possibly that there have been two or three periods, and what the mother means is that menstruation has not been "regularly established." Older females will often lead us astray by stating that they have not been regular for so many months, meaning not that no period has occurred, but that it has been deficient in some respect; indeed, sometimes they will make the same statement when the loss has been, in their own opinion, excessive. Again, we meet with females of all ages who, disliking to be interrogated upon this subject, or upon the state of the bowels, or (perhaps even more frequently) upon the state of the urine, will deliberately try to put a stop to our inquiries by telling us point blank that in these respects there is nothing whatever the matter with them. These and such-like misstatements, prompted no doubt by a sense of delicacy, may, by misleading us, be most injurious to themselves. To revert to the subject of anæmia: that term, and not chlorosis, has been used advisedly. That all cases of anæmia in young women are not to be correctly styled chlorosis may be admitted. But does it necessarily follow that they differ in kind? It is held by some authorities that they do; and we are by some told that chlorosis is a neurotic disease. That is a term which in this connexion does not convey to my mind any distinct meaning. To those who use it, it conveys only, so far as I can make out, the idea that the disorder depends primarily upon some as yet undiscovered aberration of a nervous centre at present unknown. Undoubtedly attenuation of the blood may arise from other causes than direct loss of it. Amongst these may probably be included mental depression, [illegible]

As a matter of fact, disturbances of the physiological constituents of the blood-mass do in different persons produce different effects. If the general influences of the blood on the tissues are impaired or interfered with, some tissues or parts will suffer more than others. One patient's characteristic of incapacity [illegible] some active tissue. This inability to [illegible] tissue, to be supplied by [illegible] of the [illegible] tissue, due either to local [illegible] very improbable that we have [illegible] dependence of chloranæmia upon nerve disorder. A formidable objection to this theory will at once occur to many minds: cases of chloranæmia with amenorrhœa, in which a return of the period is followed by an amendment in other respects, which previous treatment had failed to procure. I pass by the explanation that possibly the flow was the first expression of returning health. It must be kept in mind that the effects of loss of blood are of two classes: one, the depression of the system at the time; the other, the totally opposite condition of "hæmorrhagic reaction."

Probably in no case would the use of venesection be more unanimously reprobated, be regarded as more inconsonant with modern views, than in long-lingering subacute rheumatic fever. Many years ago a physician, than whom no one was more profoundly acquainted with symptomatology and with the therapeutics of the old school, no one a more acute observer—the late Dr. Eccles,—made to me an observation which seemed to me then, as it seems now, a most remarkable one. It was that in several such cases, which had thwarted his best advised efforts, recovery, speedy and complete, had followed venesection.

Another consideration is by no means unimportant. While a disastrous disappointment may be concealed, so, on the other hand, may be the renovating buddings of hope; hope based oftentimes on circumstances so commonplace, or attentions so trivial, as to escape the observation of the most sympathising and watchful relative; hope sedulously concealed from the most intimate and trusted friend; hope almost unconsciously entertained by the patient herself. We are thus often left in ignorance of that indisputably potent factor in the well-being of a girl—the "state of her heart."

It seems to me a truism, the formal statement of which almost requires an apology, that a repeated loss of blood must produce anæmia unless the system is able in the interval to replace that which has been abstracted. Protracted clinical observation has made it appear to me just as true that, as a matter of fact, the system is in innumerable instances unable to effect this replacement; that, indeed, it is not unfrequently unable for a time to replace that which is lost by a first, even if small, menstruation.

The following quotation from one of the greatest clinicists of this century commands at least respectful consideration. "I may add," says Niemeyer, "that, according to my observation, obstinate chlorosis attacks all young girls without exception in whom the menses have appeared in the twelfth or thirteenth year, and before the development of the breasts and pubes"; that is to say, before the blood-forming apparatus is sufficiently active to do more than replace blood consumed in ordinary wear and tear.

It will be here convenient to remark that probably race and climate, and also no doubt other conditions, have something to do with the development of anæmia and the phases of chlorosis. During the first six or seven years of my medical life I was familiar with the practice of the Derby Infirmary. A notable feature there was the number and severity of these cases. Nor did this circumstance seem to be entirely due to the fact that the patients were many of them employed in the large hot rooms of silk-mills. When I came to Birmingham as house-physician to the General Hospital, I was struck by the comparative infrequency of severe cases; and although no doubt a good many minor cases applied for relief, these did not seem to me at all proportionate to the difference in the population and in the number of patients.

It is interesting to observe that the opinion of American writers is very strongly in favour of the neurotic theory of chlorosis. Now, so far as I have had opportunity of forming an opinion, it is that among the inhabitants of the United States are to be found an eminent proportion of neurotic constitutions. There seems, at any rate, reason to think that here, as elsewhere, the justness of our ultimate conclusions is likely to be proportionate to the breadth of our survey. Indeed, it seems to me to be antecedently probable that the secondary or more remote effects [illegible] be different in those whom we call neurotic subjects to what they would be in persons whose nervous system is differently constituted.

It will be convenient here to offer a few [illegible] upon the meaning and objects of menstruation. A superficial glance at the respective phenomena [illegible] a resemblance, and so suggests a possible [illegible] the periods of the human and the [illegible] females. It requires but little further [illegible] guish differences as marked as the resemblance.

Digitized by Google

this latter evidence it has been concluded, in my judgment prematurely, that no analogy existed between these two physiological processes.

Evolution, though it may not prove to be the highest theory possible in the future, is one which has unravelled many of the mysteries of nature. And no inquiry of the kind now under our notice can claim to be exhaustive which has not called in this theory to its assistance. In the lower mammalia, intromission is not permitted during the intersextual periods, and therefore it is only during the *œstus* that impregnation is effected. There is not, so far as I know, any direct evidence to show whether, if permitted, it might be, or could not be, effective. In the human female these conditions are practically reversed. It is during the intercatamenial period that congress is permitted, and there is reason to believe that impregnation may occur at any date between two periods. Such an antagonism is certainly formidable. Its force is enhanced by a statement recently made in an article on the Theory of Menstruation, by Dr. Mary Putnam Jacobi, who says, "Neither can any such rhythmic alternation of sexual instinct be demonstrated in women as could lead to the inference that the menstrual crisis was an expression of this"—that is, of *œstus*.

This statement, in consequence probably of a pardonable euphemism, is somewhat obscure; but if it means what I take it to mean, I am obliged in the most unqualified manner to deny its accuracy. It seems to me to be generalised from insufficient data—that is, to be more or less a reasoning from the particular to the universal; or, if true in America, it would indicate that there is there a wider departure than in other countries from (what I am about to suggest is) the original type. It is a matter upon which, for obvious reasons, it is somewhat difficult to acquire numerous facts; but no doubt exists in my mind that it is far from exceptional to find that there is an extreme enhancement of concupiscence in the immediately precatamenial period. There is also, I believe, a general concensus of opinion that proximity to the period increases the likelihood of impregnation. I am satisfied that evidence is obtainable that in some instances ardour is at its maximum during the actual period, and suspect that cases occur in which it is almost, if not entirely, limited to that time. All this points to the probability that we are dealing with a typical example of evolution. That the period is a partially, though far from a completely effete, *œstus*.

This aberration from the original type is coincident with, and probably correlative to, other changes in the intersexual relations: the continuous affection of the woman for her husband, as contrasted with the intermittent, but when present irrepressible, attraction of the lower mammalian female to the male; the abiding love of the mother for her child, as contrasted with the ferocious defence of its young by the lower mother during the period of lactation, and the utter estrangement between them shortly after and for ever. This theory, speculation if you like to call it so, suggests why, in the interest of the perpetuation of the race, the sextual periods should recur at shorter intervals than in the lower animals, where the proclivity to congress, being purely instinctive, is more immediately imperative, and is not impeded or thwarted by the interference of higher psychical centres. Why the period should be of a twenty-eight day type, instead of any other number of days, is a mystery. The only other twenty-eight day type that we know is the moon's, and, secondarily, that of the tides. It is conceivable that the catamenial cycle may have originally coincided with the lunar phases, and the existing non-coincidence is another evolutional departure from the primitive type.

The ovulation theory has of late received a serious, perhaps fatal, blow from the fact that in a number of cases menstruation has continued after the removal of both ovaries. But we are not at present in a position to affix limits to the persistence of an acquired organic habit. It is, therefore, not quite certain that this continuance of the periods may not be an example of such persistence. I have my doubts whether the ovulation view is scientifically entitled to rank as a theory. The same remark applies to the salpingeal view. Even were it proved that the first overt act of menstruation is the grasping of the ovary by the tube, this would seem to me to be, not a theory, but a fact, though a fact of the very highest significance and importance. I should claim it as strong corroboration of the sextual hypothesis, that the first overt act, and, if it were so, *primum mobile* of the period, should be one so eminently conducive, if not essential, to impregnation.

Any complete theory must explain not only the mechanism of the period, but its recurrence. Now, in the case of all periodical manifestations the causes of which we have been able to fathom, we find the cause to be a continuous one. Day and night, the changes of the seasons, the ticking or striking of a clock, regularly recurring phenomena, are each due to a continuously acting force. The theory of Dr. Mary Jacobi has this claim to attention that it is based upon systemic changes continuing during the intermenstrual period. One of these—the progressive increase of urea—has not yet, perhaps, been unimpeachably established. Another—the progressive increase of arterial tension—is of great significance. In other recurrent hæmorrhages, notably in epistaxis, we find with great uniformity an antecedent state of high arterial tension. The old prognostic of hæmorrhage—slow pulse—is really an example of antecedent high arterial tension, followed by outpouring of blood. The immediate or, as it would formerly have been termed, proximate cause of the catamenial discharge she holds to be an enlargement of the peri-uterine plexuses, an enlargement in which the state of the arterioles must needs be a factor. This, commencing early in the menstrual interval, reaches its maximum at the following period. These views are to me extremely interesting. Clinical experience has for a long time pointed out to me the importance of using such drugs as the bromides and ergot systematically during the interval, when the object is to limit the amount of blood lost at the period. Such treatment appears to me of great advantage, inasmuch as in a large number of persons the amount lost is somewhat in excess of the reproductive capacity of the body. This theory, then, confirms the propriety of this therapeutic method by explaining its *modus operandi*.

We appear to have wandered somewhat far from the topic immediately before us. But, in the first place, it is impossible to consider the subject of first menstruation, adequately, without a consideration of the subject as a whole. In the second place, it is not conducive to sound therapeutics to draw a too stringent line of demarcation between commencing puberty and the disordered effects of its establishment, or those which may subsequently attend its continuance.

In well-developed, strong, healthy girls, we ought certainly to abide events without interference. In such we can only assume that the uterine system is less forward in its development than the system at large. Statistics show that fifteen years is the age at which, as compared with any other ages, a first menstruation is most common. But, on the other hand, there are a large number of persons in whom it is delayed for two or three years, and in not a few even later. With regard to girls who are healthy and strong, but of somewhat backward development, it is still more imperative not to interfere.

When we come to deal with the next class—that, namely, of well-developed but more or less unhealthy girls—there is room for more doubt. It is certainly a popular opinion, both within and without the profession, that there is no room for any doubt whatsoever. Menstruation, it is said, is a physiological process which ought to have come into operation, and it is our duty to establish it *vi et armis*. When there are repeated but ineffectual efforts, I think we are right in considering that nature is asking for assistance and should have it. Or, if the disorders distinctly indicate a disturbed balance of the circulation, I think we should interfere; still more, if this disturbed balance manifests itself by hæmorrhages. If the blood is to be lost, it is better, probably, that it should be lost in the natural manner. Some authorities of admitted repute refuse to recognise the existence of such a disorder as vicarious menstruation. It does not seem to me to make any exaggerated demand upon our credulity or imagination. If we admit an antecedent progressively increasing arterial tension before each period; if we admit the frequency of such an increased tension connected with other hæmorrhages; if we admit that the circulation in various parts of the body, and consequently the distribution of the blood, not only may be, but often is, affected by the menstrual *sinus*—then I think that it is not difficult to admit the possibility of vicarious menstruation.

No doubt it is not correct to assume that in every case where hæmorrhage from some other part and amenorrhœa coexist we have an example of this disease. For example, it is easy to understand that a girl may have an ordinary loss of blood from a gastric ulcer, and subsequent amenorrhœa in consequence of that loss not having been compensated.

Digitized by Google

That I would admit, but I should ask to have it admitted, on the other hand, that, in a girl with gastric ulcer, it might happen that the disturbance of the circulation, coincident with or due to a menstrual *nisus*, might determine a hæmatemesis, which otherwise would not have happened. Any careful attention to the prodromata of the period will show frequent instances of the cotemporaneous disturbance of the circulation in other parts.

Sir Charles Locock, not a mean authority, believed in the existence of menstrual epilepsy. It is now a matter of ancient history, but perhaps worth while recalling, that it was for such cases he recommended the use of bromide of potassium. The use of that drug was subsequently extended to other cases of epilepsy, and we all know with what splendid results. Since then its use has become widely spread to other cases, often wisely and seasonably, but, on the other hand, too often unwisely and unseasonably. The lungs often afford evidence of the effect of the *nisus* upon distant organs. I have seen cases of true menstrual asthma—that is, asthma coincident with the *nisus*—passing off with the establishment of the period, and absent in the interval. In persons suffering from a bronchitis, more or less chronic, interferences, if less conspicuous, are infinitely more common; just, indeed, as bronchitis is an infinitely more common disease than asthma. If a bronchitic patient in whom the expectoration is easy, copious, and thick, is exposed to a chill, and the expectoration immediately becomes scanty, viscid, and difficult, we readily accept the view that cold has been caught. We find no difficulty in associating the change of symptoms with a change in the circulation of the mucous membrane. What difficulty, then, is there in conceiving that the circulatory disturbance attending the *nisus* should disturb the already ill-balanced circulation of the bronchial mucous membrane in a superior degree to that of other parts whose circulation is well balanced? If the associated disorders are not very distinctly and directly connected with the state of the circulation, we should be more chary of direct interference; that is to say, more reluctant to attempt to precipitate the advent of the menses.

What applies to the treatment of such cases applies also to that of the irregularities of a later period, and the attendant anæmia or chloranæmia. It is, doubtless, of advantage that we should be able to take a wide and comprehensive view of any case; that we should plant our therapeutics upon a broad basis, and so avoid trying to adapt our remedies to every little turn and phase. We thus may hope to avoid a tinkering and feeble treatment; to avoid grasping at the shadow and missing the substance. But it is of equal importance that we should retain the power, and on occasion exercise it, of disintegrating a case into its compound parts. For it happens from time to time that what seems only a part may yet be greater than the whole. It is especially necessary to bear this in mind in the case of any disorder for which we have a reputed specific. In the anæmia of girls both theory and experience combine to show that we have something approaching to a specific in the preparations of iron; but they do not always succeed. It is very likely that these failures may appear to a consultant to be more numerous than they do to others. A considerable proportion of the cases which come under their notice are what we may call therapeutical misfits—cases in which the diagnosis of the disease as a whole has been correct, and the treatment in full accordance with established rules. In such cases it is that we ought to cease to regard the disease as a whole and look at the details of its compound parts. Two recent examples occur to me. In one, the patient had failed to respond to a routine treatment skilfully adjusted. On analysis of the symptoms, the most striking special feature was the rapidity of the heart's action and the deficiency of arterial tension. Treatment, mainly by belladonna, regulated these, and general relief was procured. In another case, which indeed has been before me since the lecture was commenced, a well-marked chlorosis had not only not yielded to iron treatment, but had under it become markedly worse. Analysis of this case seemed to show that its special feature was chronic gastric catarrh. Treatment founded on this view, and mainly by ipecacuanha, was followed by immediate and progressive improvement, which has proved permanent. There is nothing very mysterious in such cases. Assuming that anæmia and chlorosis are expressions of the fact that the blood lost at the periods has not been made up, they are very clear.

Without entering into any vexed question as to where new red corpuscles originate, we shall all most likely agree that the integrity of various parts is necessary to their completion. If so, it necessarily follows that imperfection in any one of these parts may be responsible for their insufficient reproduction. Over-feeding, under-feeding, over-exercise, under-exercise, insufficient air, undue exposure, late hours, or too much bed, too much brain-work, perhaps too little, too rapid growth—any one or more of these may prevent the restoration of the blood; they may also prevent that normal plethora of which the first period is the normal cure. The brunt of any of these unhealthy influences may fall upon any one organ rather than on another. The practical inference from these considerations is that we should, at all events, delay interference in cases of afferently retarded menstruation, or of subsequently developed anæmia, till we have satisfied ourselves, by minute inquiry, that such causes have been removed, and until we have at least made a vigorous effort to rectify any functional aberration of the viscera.

As regards the last class of cases, those in which the girl is not only backward in development, but also in an indifferent state of health, no doubt we do see instances of improvement following, and sometimes apparently due to, menstruation. In some such it may be that its occurrence is an indication that the developmental forces have made a spring, of which the fresh result and sign is the period. In other cases, it may be that the sudden call upon the blood-forming organs has roused them to a response—a circumstance which, as we have seen reason to believe, may happen from the artificial removal of a portion of blood. But, if we free ourselves from a blind belief in menstruation as a sort of physiological fetish, we see other cases—cases in which the patient is precipitated by a first menstruation, or by two or three repetitions, not into a better, but into a worse state of health, and often into phthisis. One such case of phthisis has come under my notice within the last few weeks. I am quite willing to admit that this is rather a question of interpretation than of fact. No doubt, many who would admit the existence of such a case as the last, and the sequence of events, would regard it from a different point of view. They would consider, not that the menstruation had killed the child, but that a case on which such a beneficial act had failed to act beneficially was intrinsically hopeless and incurable.

Well, I ask you to study this subject for yourselves; you have plenty of opportunities. Study it dispassionately; lay aside the too common prepossession that a moderate discharge must necessarily be beneficial, and cannot possibly be injurious. Ascertain minutely, and consider, without prejudice, the primary and secondary effects of each such discharge upon the individual patient. Compare these with the well-ascertained effects of artificial or of other natural hæmorrhages, large and small. If you will do this, I think some of you will come to the conclusion that, if I have now overstated the case on one side, you have in your own minds been accustomed to overstate it on the other.

Clinical Lecture

ON A

CASE OF THORACIC ANEURYSM TREATED BY A NOVEL METHOD.

BY RICHARD BARWELL, F.R.C.S.,

SENIOR SURGEON TO CHARING-CROSS HOSPITAL.

GENTLEMEN,—I desire to call your special attention to this case, which most of you have watched, and I believe with considerable interest, for some time past. The man (aged thirty-nine) was sent to me by Dr. Churchill of Chesham, and was admitted into the hospital on October 7th, 1885. Twenty years ago he had a chancre, and suffered, but not severely, from secondary syphilis for about eight years. Till ten years ago he drank a good deal, chiefly beer. His present illness began three years ago with pain in the right mammary region. After a few months his breathing became embarrassed. He first noticed tumefaction about a year since. I will detain you but a short time with a description of his condition on admission. The particular

Digitized by Google

symptoms, studied very closely as they were throughout their modifications, are of no great importance for my immediate purpose, which is to give you details of a new mode of treatment and my reasons for adopting it.

When the man came into the hospital he had a plainly visible tumour commencing above at the left side of the sternum, between the first two costal cartilages, very close to the middle line, and running thence obliquely downwards and outwards to the lower border of the third cartilage, two inches from the middle line. The length was four inches and a quarter; the breadth of the enlargement was three inches and a half. Not the tumour only, but also its pulsation was visible; the beat seemed very close to the hand. The sac at that part was very thin. Over this space there was no bruit, but the second sound of the heart was strongly marked. No fulness of surface veins was present. The radial pulses were equal, or nearly so. There was no evidence of pressure on the œsophagus; but considerable pressure—not probably on the left bronchus itself, but on some of its branches—was evidenced by the absence or diminution of breathing on the lower part of the left lung, by the peculiar notes, the mucous râles and dulness, and by the extremely troublesome cough, with expectoration of muco-pus.

The diagnosis was an aortic aneurysm, large, probably very large, springing from the lower or concave part of the arch, and progressing both forwards and backwards. In such a case any deligation of vessels was evidently out of the question, and I treated him by rest and restricted diet; in consideration that he had had syphilis, also by iodide of potassium[1] for a few weeks, by small doses of aconite, and by the salicylate of atropia. You will remember that under this treatment the man, though his condition varied considerably from time to time, certainly improved up to the beginning of the year 1886; indeed, in the earlier days of January the pectoral tumour had so far diminished that the chest was almost flat. Then began a period of exacerbation, the cough became worse, and the tumour, both intra- and extra-thoracic, increased. I need hardly say that when this aggravation set in my mind was greatly occupied with considering whether any more directly surgical method might be available; the only ones that appeared to me at all feasible were electrolysis or the introduction of a foreign body—wire, horsehair, catgut, or the like. The result of neither method is encouraging. It is true that of 37 cases of aortic aneurysm recorded by Ciniselli[2] he gives 6 cures, but this differs so widely from other statistics that I can hardly accept it. Dr. Vivian Poore[3] gives a much smaller number of cases, with 6 deaths. The latest writer[4] gives of aneurysm of the thoracic aorta 114 cases, with 69 benefited, 38 deaths, and 45 failures; but of the 69 benefited, the benefit, whatever it might be (if any), lasted but a few months in 37, not a longer time than might be accounted for by rest, not so long a period as that during which the symptoms of this patient had improved.

Let us turn to the other method. Foreign bodies, such as are named above, have been introduced eight times, and in all without success, save in a case of brachial aneurysm too small to furnish any data.[5] And yet both these methods recommend themselves to our reason; they seem as if they ought to succeed. What, then, is the cause of failure in every or very nearly every case? The question is important, because if the correct answer can be found it may help us to eliminate the cause or causes of failure, and lead us to success. Electro-puncture, when so carried out as to avoid irritation on sloughing of the sac—in other words, so as not to be injurious,—fails, I believe, for the following reasons. The cases in which it is used are of necessity large aneurysms, with sacs capable of containing twenty, thirty, or more ounces of blood, and into this large space from one to four needles are inserted. If these be connected with the positive pole, a hard but very small clot will be formed round each needle. It seems to me that the difficulty, the rarity of success, depends on the very slight influence that one, two, or three little nodules of coagulum can have on so large a mass of blood. If, now, we consider the other method, we find in all probability an opposite defect—namely, the wire or other substance occupies a considerable space in the sac; and I think there is little if any doubt that the blood will coagulate round substances thus introduced; but the clot is very soft, of that sort which Broca called passive; it is unstable; and some clinical facts show that such clot may be redissolved, and there is possibly also a danger that some shreds of it may be washed away in the form of embola. This review of the probable cause of failure of both methods led me to consider that if we could increase the area of galvanic action, or increase the hardness and stability of clot formed on foreign substances, we might be led to a successful method. This it seemed might be effected by introducing into an aneurysmal sac steel wire arranged to lie in wide coils, and then by passing along it a carefully regulated galvanic current.

By this time the patient was in a very critical state; both lungs admitted but very little air, in places none at all; his cough was very painful and constant; the expectoration frankly purulent, the wave of blood in the extra-thoracic part appeared almost subcutaneous. In the mechanical arrangements there was a little difficulty; an ordinary trocar and cannula, such as have been hitherto used for passing wire into sacs, was evidently unfitting on account of its conducting power. A tubular needle of vulcanite with a steel tip and several other devices were procured and rejected. At last a tube of ivory sharpened like a hypodermic needle was accepted as the most feasible arrangement. On March 2nd, the skin being rendered insensitive by the injection of cocaine, a fold was pinched up and a little incision made from within outwards over the tumour; the ivory needle was then thrust in without difficulty and about ten feet of the finest steel wire passed into the sac. The wire, having been first wound on a wooden cylinder half an inch in diameter and being of the best steel, must, after being paid through the needle, coil itself up again in the sac. Dr. Murray had kindly undertaken the management of the galvanic arrangements, whom I must thank for the great pains he took to carry out the intentions which I had explained and for writing the following short account. "The wire was connected with the positive pole of an eight-celled Garnet's battery. The negative was applied to the upper dorsal region a little to the left of the middle line. Between the electrode and the skin was interposed a piece of amadou about a foot square, thoroughly saturated with hot water. A galvanoscope and a voltameter (Gaiffe's) were included in the circuit. The resistance in the voltameter was so great that the strength of the current did not exceed four milliampères. Twenty cells of a Coxeter's "practitioner's voltaic battery" were therefore added to the Garnet battery, and the current strength was raised to about nine or ten milliampères. At this level it was maintained during the operation. The current was passed for an hour and ten minutes. Some redness of the skin was caused by the negative pole, but no indication of irritation at the place of puncture." For twelve hours signs of consolidation were absent, or nearly so; but at the end of that period the pulsation seemed considerably more distant and the tumour much harder, and this change rapidly increased. The lungs began to unload themselves of their accumulated pus and muco-pus; expectoration, very difficult previously, became easy and somewhat copious, showing decrease of pressure on the bronchi. But on March 5th (fourth day of operation) a new tumour appeared to the right of the sternum and rapidly increased. The man also became weaker. He died on March 9th, a week after the attempt, partly from exhaustion, and partly, as it appeared, from rupture of this second sac.

At the post-mortem it was found that the interior of the bronchi were of a deep-purple colour; in places the mucous membrane was nearly or entirely absent; the substance of both lungs airless and tough, sinking in water, but not from inflammatory consolidation. I have elsewhere remarked on this condition,[6] and will not now detain you with a further description. The very large aneurysm occupied the concave aspect and lower part of the front of the first and second part of the aorta; it had eroded a portion of the sternum and the ribs; the anterior portions of the almost solid lungs, more especially of the right lung, seemed to form part of the sac. On opening the aneurysm, it was found to consist of two parts: a left portion, much the larger; and a secondary or right portion, which seemed to

[1] Under this drug the sac wall seemed to become thinner.

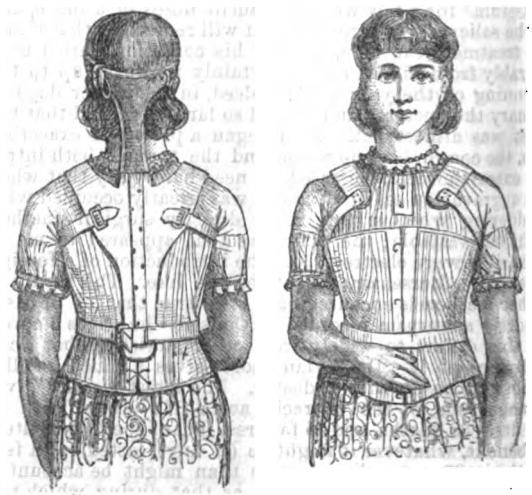
Digitized by Google

have recently increased in size, and which, where the lung formed a part of the wall, had burst and given exit to 2 lb. 8 oz. of blood, which was found in the right pleura. The left portion contained large wide coils of steel wire, each of which was surrounded by a pretty thick coat of firm colourless fibrin, strongly adherent to it at many places—that is to say, wherever the metal was in contact, or within a moderate distance of the wall, the wire was bound to the sac by this fibrin, thus greatly increasing its strength and resisting power.



Now let me especially point out to you that my attempt was evidently too late; the man's lungs were already all but useless. The conformation of the aneurysm also was unfortunate, in that it possessed a secondary sac, into which my wire could not pass—not a new one developed after the operation, for the man told me in writing three days before his death that the tumour to the right of the sternum had existed two years previously. The endeavour to save life was by these circumstances frustrated. But consider what the condition of things found in the large sac means. Evidently it means that by passing a galvanic current not merely along two or three needles, which are afterwards removed, but along some feet of wire which is left *in situ*, we have a device by which a considerable quantity of hard, firm, and persistent clot can be produced in large quantities even though, as in this case, the aneurysm may be close to the heart. I hope I am not too dogmatic in saying that if a galvanic current and coils of wire are to be of service in such cases, they will only be so when used in combination, after the manner thus illustrated.

REST IN THE TREATMENT OF SCROFULOUS NECK.

BY FREDERICK TREVES, F.R.C.S.,
SURGEON TO, AND LECTURER ON ANATOMY AT, THE LONDON HOSPITAL.

SINCE surgery had a place in literature the treatment of scrofula has been the subject of considerable discourse. Upon few matters has the ancient writer of medicine proved more verbose and demonstrative. Like other chronic and protean maladies, scrofula has attacked and absorbed the pharmacopœias of successive generations. The strumous being has afforded ample material for experiment, and in few diseases has the subject been less affected by the manifold changes in its therapeutic environment. The treatment of this disorder has not possessed perennial interest. It has rather aroused from time to time a paroxysmal concern in the surgical mind, and its place in the history of medicine has been marked by a series of literary gusts. One such gust has lately blown. After a long period of neglect the treatment of strumous diseases has been refurbished with great vigour by certain continental surgeons. Considerable additions have been made to the burdened literature of the subject. Various new modes of treatment have been devised that are without doubt excellent, that have been well founded, and that are likely to prove of permanent value. They have been introduced and extensively adopted in this country, and are to be credited with very admirable results. Under the circumstances, therefore, some excuse is needed for adding to the further discussion of the subject. Limiting the excuse to the conditions covered by the term "scrofulous neck," it has appeared to me that there is at least one thing lacking in even the most modern modes of treatment. This one thing, I venture to think, can claim so paramount a position among the local methods of treatment as to render those methods inefficient when employed alone, and insignificant when placed in comparison or competition. This therapeutic factor consists merely in securing rest for disturbed parts. It cannot therefore be considered to be in any way new in theory, although it is, to the best of my belief, not yet recognised in practice, so far at least as the present affections are concerned.

The treatment of inflamed and damaged structures by rest can claim an antiquity that it shares only with the earliest records of surgical science. Viewing the matter from a liberal standpoint, it may be said that the familiar procedures directed against inflammation and disturbance are little other than ingenious and manifold applications of this rudimentary principle of treatment. It is strange that some of the commoner affections of the neck should have been considered exempt from such elementary influences where the art of their healing is concerned. It is needless to point out that scrofulous gland swellings in the neck, together with scrofulous abscesses and the sinuses that result therefrom are, as a rule, very chronic in their course, and very obstinate in their relation to treatment. There is little in the anatomy of the neck to account for this. The part is vascular; it is easy of access; it is not dependent. The arrangement of the cervical fascia is certainly obnoxious to the easy progress of an inflammation, but in many of the most indolent cases this fascia is in no direct manner concerned. There is this, however, to be noted: that the neck is a part of the body that is in almost constant movement, and if rest is of real import in the treatment of inflamed tissues, then there can be few parts of the body where it is more clearly demanded than it is in this place. If in the axilla or the groin there be a glandular swelling or a chronic abscess or a lingering sinus, the first injunction to the patient is an injunction to rest. Few would undertake the care of such cases if the patient persisted in continued movement of the limb. Yet there is this anomaly—that when like disorders are met with in the neck the need of rest is overlooked, and it may be possible to see an individual with a sinus about the elbow treated by splints, and a like sinus below the jaw treated without restraint of any kind. It is difficult to understand how an inflamed gland situated beneath the sterno-mastoid muscle can heal so long as it is kept in a constant condition of unrest by the movement of that

muscle, and it is still more difficult to conceive an easy and wholesome career for a sinus or an abscess cavity so placed. I would venture to urge that the employment of rest should be a routine measure in the treatment of every case of scrofulous neck; that it should supplement all other local procedures, and among them hold a predominant place. The application of this measure may be considered before the detailed treatment of the affection is discussed.

To secure rest to the neck I originally used a simple "stock" of gutta-percha.[1] This I found to be somewhat cumbrous and uncomfortable, and not applicable when any disease existed about or below the inferior maxilla. Moreover, the stock concealed from view the seat of trouble, and required to be frequently removed. For the last three years I have made use of a splint, the main features of which can be gathered from the annexed woodcut. It is made of felt, and takes its fixed point from the shoulders and back. The centre of the splint is strengthened by a slender strip of metal. This strip is carried up along the back of the neck, and at the occiput meets a cross-piece which is moulded to the outline of the skull. The cross-piece is kept in place by a narrow ribbon that encircles the forehead. In young girls and women the cervical part of the splint can be entirely concealed by the hair. The splint in children and in males may be secured by straps, as shown in the figure; in adult females it may be more conveniently attached to the stays. The felt is freely perforated, and the whole appliance is exceedingly light. It has been made for me by Messrs. Krohne and

Sesemann. I have made extensive use of this simple apparatus. It keeps the neck still, but not rigid, and after the first few days of its use it ceases to be irksome. Patients have worn it without interruption for three, six, and nine months. It is perhaps needless to say that it is not worn at night. Of its value I can speak in strong terms, and to this employment of rest I would ascribe results in some cases that I believe no other method of treatment would have secured. I have used it not only in the treatment of scrofulous affections, but also as a splint after operations upon the neck, in cases of burn and of accidental wound, in carbuncle, and also in cases of lupus that have been treated by scraping. Under these varied circumstances I have convinced myself that the healing process has been very materially aided by this simple appliance, and in many instances the wearing of the splint has increased rather than diminished the patient's comfort for the time being. So much for this one measure. It will now be convenient to consider the treatment of scrofulous neck in general terms.

Scrofula and the pathology of the scrofulous process have been legitimate objects for contention from early times. The matter is as yet by no means disposed of, and is likely to remain disquieted until the pathology of tubercle has been placed at rest. Some recent writers have urged, with affectation, that scrofula does not exist; but the paradox, being meaningless, does not advance the discussion. One point perhaps will be very generally allowed, and it is this—that the main phenomena of the scrofulous process are the outcome of a chronic inflammation of a low type. It is a matter of no great moment whether that inflammation is or is not produced by tubercle, or whether the tubercle is a product rather than a cause of the local trouble, or whether tubercle itself is a thing for terror, and not a phantasm or a pathological fetish. The great point still remains that the treatment has to concern itself with a condition the outward and visible signs of which are those of an ill-moving inflammation. In the treatment of the gland enlargements, it is necessary, in the first place, to bear in mind that the gland trouble is secondary, and will have followed some lesion in the periphery. The more recent the case, the more important is it that the initial lesion should be sought out. It is obviously a waste of means to treat an inflamed gland while the cause of that inflammation remains active and untouched. It is of little avail to rub ointment on a strumous gland in the neck while the coryza, or the sore-throat, or the eczema of the scalp that caused the enlargement remains untreated. A thorough examination of the lymphatic periphery should be an early care. The disturbances therein that may lead to gland enlargements are numerous and varied, and among them may be placed pharyngitis, especially that incident to measles or scarlet fever, tonsillitis, diseased teeth, coryza, ozœna, otorrhœa, conjunctivitis, eczema, and the like. To the relief of these disturbances, so far as relief is possible, the earliest treatment should be directed. In rare instances the gland mischief in scrofula may be primary, and I have seen such primary mischief in the neck as the result of a blow on the one hand, and of a definite exposure to cold on the other. A mysterious enlargement of many cervical glands coincident with the outbreak of phthisical changes in the lung is probably familiar to many.

As the next step in treatment, the general management of the scrofulous patient may be briefly considered. The more essential points would appear to be the following: The healthiest possible surrounding, with plenty of fresh air and especially of light, then residence by the sea, above all for those who live inland and in great towns. In the choice of a seaside resort, I think it matters little whether the spot be east, west, north, or south, so long as it presents this feature—a beach upon which a large extent of seaweed lies exposed at low water. Iodine is, or can be, obtained from seaweed; and it is reasonable to conjecture that this volatile substance may be given off into the atmosphere when acres of seaweed are drying in the summer sun. An iodine-laden air is an ideal atmosphere for a scrofulous person. Certain it is that those sea towns are most beneficial where this condition is pronounced; and it is to this circumstance and the fact that it lies surrounded on three sides by the sea that Margate probably owes its great repute as a place of healing. Sea-bathing, under proper restrictions, should play also a conspicuous part in the treatment. The bath should be in the open sea. A domestic sea-bath, constructed out of fresh water and salt, approaches the confines of a therapeutic burlesque. Such is the circulation in the majority of the scrofulous, and such is their disposition to catarrh, that every care should be taken to avoid exposure to fluctuations of temperature. To meet this end in some way, woollen garments should be worn next the skin both winter and summer, and the patient should keep within doors after sunset and on other than fine days.

Out of the medley of medicines employed, these may be selected—iodine, iron, quinine, lime, and cod-liver oil. Iodine in some form appears to be necessary in the treatment of scrofula, and the preparations that are the most useful are the syrup of the iodide of iron and iodide of potassium. Iron and quinine take place as tonics. Phosphate of lime often appears to be of great value, especially when suppuration exists. Sulphurated lime (commonly known as sulphide of calcium) is largely used in strumous gland affections. Its action is, however, most uncertain. It is supposed to concern the suppurative process. In many cases it has appeared to distinctly check the formation of pus, and to limit suppuration when the discharge has been fully established. In other instances its action has been simply negative. In any case of strumous disease, but especially in cases where suppuration exists, it is well to suspend in the patient's room a few crystals of iodine in a chip box. The air becomes lightly charged with iodine, and the patient is surrounded by an atmosphere that is at the least mildly antiseptic. Cod-liver oil is probably the most important medicine of all. It may be given as a mixture with tartarated iron, or alone, or in the form of an emulsion with the hypophosphites. It is perhaps best to administer it during the spring, autumn, and winter, and to omit it entirely during the summer months. Patients who cannot take cod-liver oil may perhaps be induced to increase the amount of fat in their food by the addition of fat bacon, clotted cream, and the like.

To return finally to local measures. I take it that the day of local applications is over. It is no longer a routine measure to paint iodine over the skin of the neck in all cases of cervical gland enlargement. Such painting appears to be of most use in certain chronic cases where the glands—few in number—have become quite inert, listless, and free from all tenderness. In a large number of instances it does harm, probably by adding to the disturbance already existing in the periphery. Suppuration in glands has, I think, been often determined by iodine paint used by lavish hands. In some slowly progressing cases, where the glands are not tender and there is no distinct evidence that suppuration exists, a steady rubbing of the part with the ointment of the iodide of lead appears often to effect considerable improvement. Poultices of seaweed and compresses of salt water do little more than divert the patient and increase his risks of catarrh. In early cases, where the trouble is active and progressing, the use of the cervical splint alone is the most effective of local measures. With its application the parts are placed at rest, the glands cease to be painful, and very commonly cease to increase. The same may be said with reference to chronic enlargements that have become once again the seat of active change.

So manifold are the aspects of the scrofulous neck, and so varied the circumstances that mould its clinical being, that the conditions under which certain operations are advisable can only be considered in bare outline. Excision with the knife, so far at least as the neck is concerned, can be but rarely practised. It is adapted for cases where a solitary gland or a small well-limited cluster of glands persists obstinately after other manifestations of scrofula have disappeared. Such glands should be movable, free from the adhesions of peri-adenitis, and emphatically chronic. Operations upon larger gland clusters, even when the individual tumours appear quite free, are often exceedingly dangerous. The glands are found on exposure to be less movable than they appeared, to extend deeply, and put in danger the great vessels and nerves or the dome of the pleura if obstinately pursued with a knife. Extensive operations of this kind appear to me to be rarely justifiable. Cautery puncture is admirably adapted for large perfectly indolent gland tumours that are near the skin, are fixed, and are too large for scraping and unsuited for excision. A slender cautery point is introduced into the gland and then thrust in many directions through its substance. The ill-conditioned mass inflames, its parts break down, and the cautery aperture affords a free exit for the débris that results. In many instances this measure has been most successful, and the resulting scar slight and without the conspicuous characters of the common strumous cicatrix. Scraping away the gland mass with a

Volkmann's spoon is a measure that has been very extensively employed, and is applicable to a large series of cases. It is best adapted to cases where sinuses exist, or where the gland is fixed and either breaking down or else quite disorganised. The gland so treated should not be of great size. In many instances the instrument does little more than remove the products of disintegration; in other cases the diseased but still living gland tissue is broken down and removed, and the surgeon effects in a few minutes what nature would accomplish only in weeks or months by means of the suppurative process. When no sinus exists an opening should be made into the gland with the cautery. This measure is not without risk, and it cannot deal with the gland capsule that remains behind, but in spite of theoretical objections it must be owned that the procedure answers well in practice. It is obviously not applicable to an extensive series of glandular swellings.

In conclusion, a word may be said with reference to strumous abscesses and sinuses of the neck. The former, as a rule, depend upon gland disease. The pus may be within the capsule of the gland, or, as is very frequent, in the loose connective tissue around it (peri-adenitis). In other instances the collection is independent of glandular trouble, and has to be classed with cold or tubercular abscesses. I think that in any case the pus should be evacuated by cautery-puncture. The cautery point, if very highly heated, is less painful than the knife and quite as rapid. The small opening made cannot close, and as a charred tract is established between the surface and the abscess cavity, undermining of the skin can hardly occur. The cavity should be allowed to empty itself. The fussy squeezing of a recently opened abscess that appears to be to many an irresistible temptation is strongly to be condemned. When the purulent cavity has emptied itself it is duly drained. The sinuses that are so often left in the neck after the strumous storm has passed over it are ill-conditioned and seldom amenable to one stereotyped plan of treatment. Some are best dealt with by a free incision. In others, where the tract is long and narrow and deep, the sinus may be fully dilated with a sea-tangle tent, and then carefully dressed from the bottom. In any case a free scraping of the sinus wall with a sharp spoon rids it of its feeble purposeless granulations, and puts it into a fair state for healing. The bottom of the fistula should be exposed whenever possible, for in that position it is not uncommon to find an ancient fragment of a diseased gland that has secretly maintained the mischief. It only remains to be said that in all cases, and especially in all instances where operations are performed, the inflamed and disturbed tissues must be placed in a condition of rest.

Wimpole-street, W.

THE ALBUMENS OF THE URINE.[1]

By ROBERT MAGUIRE, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE OUT-PATIENTS AND WARDEN OF THE COLLEGE, ST. MARY'S HOSPITAL.

WE are accustomed in our ordinary clinical examinations of the urine to speak of albumen being present or absent according as a precipitate is or is not obtainable by the reagents we employ, and we commonly, too, consider that the precipitate so obtained is one simple albuminous body. This is not so. The precipitate obtained by nitric acid, for instance, in an albuminous urine ordinarily consists of two distinct albuminous substances—serum-albumen and paraglobulin; it may consist of egg-albumen or of hemi-albuminose; it may be confounded with a precipitate consisting of mucin, and the urine may contain peptones when no precipitate whatever is thrown down by the nitric acid. I have thought it of some scientific interest, and, as I hope to show, not without some practical value, to review the conditions under which these different substances and their modifications may be present in the urine, and to detail the results of some observations I have made in this connexion.

It is probable that the serum-albumen present in the urine may vary in its physical, although not in its chemical, properties. Just as the original albumen of the blood-serum may, according to the researches of Dr. Halliburton,[2] be separated into at least three kinds, which coagulate at different temperatures, so in all probability the serum-albumen present in the urine may so vary. But in a complex fluid like the urine these minute differences are very difficult to prove, and it is still more difficult to avoid errors. Thus Dr. Parkes and Dr. Pavy suggested that the increase of albumen in the urine after food might be due to some change undergone in digestion, which rendered the albumen more diffusible. Lépine[3] has actually found that the albumen passed after meals is more diffusible than that passed before meals, and is more easily changed into peptone by artificial digestion. Again, Drs. Lauder Brunton and Power[4] examined albuminous urines at various intervals before and after meals; they found certain differences in the temperature at which the albumen coagulated in different specimens, but their results were inconstant. Dr. Saundby,[5] on the other hand, obtained results which were at variance with both the sets of experiments mentioned. Bouchard, again, asserted that the specific gravity of the urinary albumen, or, as he called it, the "retractability," might vary. He believed that in cases of so-called physiological albuminuria the albumen coagulated by boiling did not sink to the bottom of the tube, but floated on the top of the urine. This also has been disproved. It seems, therefore, that but little help may be looked for in our clinical work from an investigation of the mere physical differences of the urinary albumen; but a chemical investigation seems to be more promising.

I have mentioned that the precipitate obtained by nitric acid in an albuminous urine ordinarily consists of both serum-albumen and paraglobulin. Paraglobulin resembles serum-albumen in being coagulated by heat and by nitric acid, and therefore comes down together with serum-albumen in the ordinary routine of testing. It may be separated from the serum-albumen in several ways. If the urine from certain cases of Bright's disease be poured into a large quantity of water, preferably water which has stood for some time, and to which a very small amount of acetic acid has been added, a cloudy precipitate is formed. This is believed to consist of paraglobulin; it is held in solution in the urine by the small quantity of salts then present, and when the percentage of these salts is diminished by copious dilution, as in the above experiment, the globulin is thrown down. Some years ago I investigated a number of urines with the view of ascertaining when this reaction was present, and found it as a rule only when there was a large amount of albumen to be detected by the ordinary tests, and generally in advanced Bright's disease. Lately I have not been able to get this reaction with urines containing no other albumen than globulin, but this in only comparatively small quantity. It is evident, however, that the above reaction can only be a very rough test for globulin, and at the best it does not show that globulin is present in excess over serum-albumen. Senator[6] attempted to separate globulin from serum-albumen by diluting the urine and passing through it a stream of carbonic acid gas. By this method he found globulin more especially in the urine of patients suffering from amyloid degeneration of the kidneys and catarrh of the bladder; but his method, again, was very unsatisfactory.

Probably the best method of obtaining globulin from its solutions is to saturate the solution with magnesium sulphate, when the globulin will be precipitated in an uncoagulated form, and can afterwards be redissolved in water. Estelle,[7] adopting this method, found that the amount of globulin in the urine always exceeded that of the serum-albumen, and in two cases he showed that the proportion of globulin to serum-albumen in the urine was exactly that of the serum from which the albumen was derived. Now, in applying this method a very essential precaution is to neutralise the urine before adding the sulphate of magnesium. One of the best tests for albumen in urine is a mixture of five parts of a saturated solution of sulphate of magnesium with one part of nitric acid, as recommended by Sir William Roberts.[8] In an acid urine magnesium sulphate alone will form an albumen test in a certain degree similar to the above; it is true that no free acids are present, but it has been shown by Ott[9] that magnesium sulphate in com-

Digitized by Google

bination with the acid salts of the urine is sufficient to precipitate a certain amount of serum-albumen together with the globulin. All determinations in which this precaution of neutralising the urine is not adapted are liable to show an excessive amount of globulin to be present, and as it does not appear from Estelle's paper that he did neutralise the urine, it is not improbable that this may account for the large amount of globulin which he found. I am the more inclined to think this as my own observations in which this precaution was adopted showed in chronic Bright's disease an excess of serum-albumen over the globulin, instead of an excess of globulin, as found by Estelle. A similar objection of imperfection of the methods then known will also attach to the observations of Dr. Saundby, in which he found in two out of forty-two cases that the whole of the albumen was precipitated by magnesium sulphate, and therefore seemed to consist of globulin. Nevertheless, Dr. Saundby concluded that the body present in the urine which is precipitated by heat is almost invariably serum-albumen, and rarely globulin, and that the occurrence of paraglobulin in the urine is obscure, and not attached to any particular clinical group of cases.

Still another method of separating globulin from serum-albumen has lately been recommended by Hofmeister and Pohl,[10] in which use is made of the fact that if albuminous urine is treated with sulphate of ammonium, the globulin is precipitated when the amount of sulphate of ammonium reaches 24·11 per cent., while the serum-albumen is not thrown down until 33·55 per cent. of the salt is dissolved. There are various sources of fallacy in connexion with this method which render it somewhat unsatisfactory, and before adopting it I preferred to wait until further observations might prove its value. I have therefore made use of the sulphate of magnesium method in the investigation of a number of albuminous urines, and I aimed, not at the mere demonstration of the presence of globulin, but at a percentage determination of the relative amounts of serum-albumen and globulin respectively in different cases and at different stages of the same case. In each experiment fifty cubic centimetres of the urine were first neutralised by liq. potassæ, and to them was added a considerable quantity of magnesium sulphate. The mixture was then placed in an incubator and maintained at a temperature of about 40° C. for at least twelve hours. It is advisable to warm the mixture in order to ensure the complete saturation of the urine by the magnesium sulphate, but it is essential that the temperature should not be raised sufficiently high to coagulate the albumen, since then serum-albumen would come down together with the globulin. During this period the mixture was well shaken several times, and if necessary more magnesium sulphate added until some remained undissolved. The solution was then filtered, the filtrate containing the serum-albumen, the precipitated globulin remaining on the filter-paper. This was well washed with a saturated solution of magnesium sulphate, the washings being added to the filtrate. The filter-paper containing the globulin was now digested in water at a constant temperature, and a solution was thus obtained containing the globulin of the original urine. The serum-albumen and the globulin in these solutions were estimated by the nitric acid dilution method. Since the object of the experiments was to ascertain the *relative* amounts of globulin and serum-albumen—and any error in the method would apply equally to the solutions of each of these—it was thought that this method of estimation was sufficiently accurate for the purpose. Manifestly, the method, especially in the presence of magnesium sulphate, is not accurate enough for exact and absolute determinations, and I am at present engaged in controlling the estimates by the more tedious process of weighing. Examined in this way, I found that the proportions of globulin and serum-albumen varied exceedingly in different urines. The first case I have to mention is one of granular kidney, with albuminuric retinitis.

CASE 1.—Thos. G——, aged forty years, was admitted into St. Mary's Hospital under Dr. Cheadle in March, 1886, and came under my care in Dr. Cheadle's absence. The family history presented no remarkable points, and his habits had been temperate. Twenty-four years before he had suffered from disease of various joints, causing ankylosis of the left elbow, and rendering necessary an amputation of the right leg. For more than twenty years, however, there had been no active joint trouble. I mention these details to show that there was present no cause for amyloid disease. The patient had never had scarlet fever or diphtheria, but had been exposed to wet and cold. The first symptoms of his present illness showed themselves eight months before admission by frequent attacks of vomiting and headache. Two months before admission his eyesight became dim. On examination the patient was somewhat pale and puffy, and a slight amount of œdema was noticed in the leg. The pulse showed very high arterial tension. The apex beat of the heart was in the sixth interspace and in the nipple line. There was a prolonged first sound of the heart, and the second was remarkably accentuated at the aortic cartilage. Several hæmorrhagic and many whitish spots were seen in each retina. The urine was copious, very pale, sp. gr. 1010, and reaction acid; it contained albumen and hyaline casts. On examination by the magnesium sulphate method, I found that in 50 cc. of urine there were 0·02125 grm. of serum-albumen and 0·0085 grm. of globulin. This would show the relation of albumen to globulin to be as 2125 to 850, or about 2½ to 1.

CASE 2.—According to its clinical appearance this case was also one of granular kidney, but complicated by mitral stenosis. Lucy B——, aged thirty-three and married, was admitted under Dr. Broadbent on April 2nd, 1886. She had suffered from rheumatism three years before admission, had been exposed much to wet and cold, and had undergone great privations. About six months before admission the patient had an attack of hæmoptysis, and four months afterwards her feet began to swell. Without going into details with regard to the present condition, I may say that there was a presystolic murmur heard at the apex of the heart; the apex beat was situated two inches below the nipple and in the sixth interspace, while it was also somewhat more to the left than is normal. The pulse was of higher tension than the mitral stenosis would account for. The urine was pale, neutral in reaction, sp. gr. 1016, and contained a considerable amount of albumen, stated in the clinical report to be one-third. Here we evidently had to do with something more than the ordinary cardiac kidney, and the low specific gravity of the urine, the high tension pulse, with the evident hypertrophy of the left ventricle when there was only mitral stenosis with no regurgitation, pointed pretty clearly to a diagnosis of granular kidney in addition to the cardiac affection. After rest in bed for a few days and medicinal treatment the œdema of the legs and the cardiac distress present on admission disappeared, and it was only after some days that I obtained a specimen of urine for examination. This showed in 50 cc. 0·0292 grm. of serum-albumen and 0·0076 grm. of globulin, or about 4 parts of albumen to 1 part of globulin.

CASE 3.—This was a case of anæmia with albuminuria, the latter being due in all probability to fatty degeneration of the kidney, combined with the vascular disturbance. This patient also was under Dr. Cheadle, and came under my care for a time in his absence. There was no history of scarlet fever or diphtheria; but the patient had had one attack of rheumatic fever, followed by perfect recovery, as far as her own account could be trusted. On admission, she was exceedingly pale, and had some œdema of the lower limbs. The *bruit de diable* was well marked in the neck; the cardiac dulness was somewhat increased in extent; the apex beat diffused, not lowered, but apparently somewhat displaced to the left. A post-systolic murmur was heard at the cardiac apex, conducted best in an upward direction towards the pulmonary area. The pulse did not show very high tension. Under treatment the œdema and paleness disappeared to a great extent, and so also did the cardiac murmurs and the apparent dilatation of the heart. The urine had in the early part of the case been found albuminous, but my attention was first called to it later on. While in bed the urine was apparently normal and contained no albumen. When, however, the patient was allowed to sit up and walk about the ward for the first time, albumen appeared in the urine. During the remainder of her stay in the hospital the albumen was very variable in its appearance, but always showed in its amount a distinct relation to the amount of exercise taken. On separating the globulin from the urine, I found that 50 cc. of the urine contained 0·0560 grm. of serum-albumen and 0·01407 grm. of globulin, or 1 part of serum-albumen to 2½ parts of globulin, the exact reversal of the proportion found in the first case described.

(To be concluded.)

LIGATURE OF THE INNOMINATE ARTERY.

BY BENNETT MAY, B.S., F.R.C.S.,
SURGEON TO THE QUEEN'S HOSPITAL, DEMONSTRATOR OF OPERATIVE SURGERY AT QUEEN'S COLLEGE, BIRMINGHAM.

AN annotation in THE LANCET of April 3rd favoured with special notice the case in which, seven days previously, I had tied the innominate artery for aneurysm. The patient was then doing well, but died from secondary hæmorrhage on the nineteenth day. This further record is from the bedside notes of our house-surgeon, Mr. A. B. Bennett.

J. N——, aged thirty, a brewer's labourer, was admitted into the Queen's Hospital on March 3rd, 1886, suffering from a large aneurysm of the right subclavian artery. His occupation had exposed him for a long term of years to great exertions and violent straining, as in carrying heavy sacks on his shoulder, and the joint of this side had been dislocated on three occasions. He had never had syphilis or rheumatism, and had been a very moderate drinker. The first symptom of the disease appeared about seventeen months previously, in the form of shooting pains down the arm and forearm, with occasional numbness of the limb; but, in spite of increasing suffering, he struggled on with his work, doing most of it with the other arm. He discovered a local swelling above the clavicle about nine weeks before admission. This steadily and rapidly grew in size, and with it the pain became more severe. He then came under the care of Mr. W. B. Sparrow, of Burton-on-Trent, who diagnosed the aneurysm and sent him to me for its treatment.

March 5th.—The tumour lies just above the inner half of the clavicle; it measures three inches in the transverse and two inches and a half in the vertical direction. On the inner side it disappears under the sterno-mastoid; externally it reaches nearly to the acromion. The common carotid artery is carried inwards towards the middle line of the neck, and can be felt distinct from the tumour, over which it can be made to roll. Pulsation in the tumour is very strong, but bruit is either extremely faint or absent. There is a pulsation in the episternal notch, obviously that of the root of the common carotid, which is prominent here. Pressure effects on the brachial plexus are marked by intense pain with numbness down the arm and forearm and wasting of the muscles. The pain, which at times is excruciating and causes extreme restlessness, appears to affect mostly the peripheral area of the musculo-spiral nerve. There is no œdema or venous engorgement of the limb, but the nails are slightly clubbed. The brachial artery, which is very superficial above the bend of the elbow, is no larger in calibre than a No. 3 catheter. The radial pulse is distinctly smaller than on the other side. All the superficial arteries are slightly fibroid. The right pupil is much smaller than the left. No laryngeal or pharyngeal symptoms exist. The chest was examined by Dr. Suckling, who found no evidence of disease of the heart or of the large bloodvessels.

Treatment.—The man was placed on Tufnell's aneurysm diet, consisting of ten ounces of light dry solid food with eight ounces of fluids daily. He would not keep recumbent, owing to the severity of his pain, which caused him to sit up in bed and roll his arm about a great deal. Hypodermic injections of morphia in frequent half-grain doses seemed almost powerless to relieve him at first. Ordered ten grains of iodide of potassium three times a day.—11th: The pain is somewhat less, the morphia being more efficacious in giving relief. Aneurysm the same.—18th: Condition much as before, but the patient is wearying of the diet, and he is thinner and weaker.—25th: The slight improvement which was at first apparent has not been sustained. Pulsation is as strong as ever, and its superficial area is much larger, while the pain is as severe as at any previous time. He is clamorous for food, and not willing to continue the restricted diet any longer.

Under these circumstances I determined upon operative treatment, and therefore abandoned all medicine and placed him on a liberal dietary for a few days. After carefully considering all the circumstances of the case, together with the results of recent experience in operations on large arteries, there appeared to me no ground for excluding our most direct and certain method of procedure—viz., the Hunterian—by ligature of the innominate artery. Accordingly on March 27th, the patient being brought well under chloroform, I made an incision along the inner third of the clavicle, and another down the line of the common carotid artery, so as to meet the first in the episternal notch. This skin flap was then dissected up, presenting veins tied and divided, the sternal with part of the clavicular origin of the sterno-mastoid cut across, and the sterno-hyoid and thyroid muscles also divided. The carotid sheath was then arrived at and opened on its inner side low in the neck. Proceeding down this artery the innominate was found. It appeared a vessel of unusually large dimensions, and was rather superficial. It seemed to be nearly an inch in diameter, but showed no local or fusiform expansion. Compression made against the sternum by a finger behind the vessel was found to control the pulsation both in the tumour and the carotid. I could not define its bifurcation nor make any approach to the first portion of the subclavian, as the structures over this vessel were matted and could hardly be identified. I afterwards found that it was flattened out over the aneurysmal sac. It was rather an arduous task to get the needle round the vessel; the difficulty was partly owing to its size, but mainly to the existence of adhesions binding the vessel to the sternum and the parts on its outer side. The needle used was an old-fashioned silver one, broad, and well rounded at the point, with a large eye, and sufficiently flexible to take any desired curve. This was passed satisfactorily round the vessel, and then threaded with a small cord, to which a strip of ox aorta material, kindly sent me by Mr. Barwell, was attached, and by it pulled through. In tightening the tape, I had to draw the ends with very considerable force to stop the pulsation, the vessel offering great resistance and pulsating with great force. Just at the critical moment, however, the material gave way and broke across, and a second piece introduced in a similar way suffered the same fate. I then endeavoured to imitate the principle of the flat ligature by using a cord made up of five or six medium-sized threads of catgut. This bore the strain very well, and after tightening with sufficient force to completely stop pulsation in the tumour and branches of the carotid, I drew on the ends still further, to allow of some subsequent relaxation in fixing the knot. At the same time I endeavoured to avoid crushing the coats of the artery. The ligature was secured with a third knot and cut short; the wound was dried from all clot, its edges brought partly together, a tube and strip of antiseptic gauze being left in one corner for drainage. The whole proceeding had been conducted under the spray and careful Listerian antiseptic details. The wound was then well padded, and covered with a gauze dressing secured by an elastic roller. On leaving the table no pulse was perceptible at the wrist or in the aneurysm. Four hours afterwards there was a faint pulse at the wrist. He had not much pain, but was restless from heat. Temperature normal; pulse 102; respiration 22. Had rallied well from the operation.

March 28th.—Seems very comfortable except for pain and burning of the arm. Temperature 98·8°; pulse (evening) 106; respiration 22. A small thready pulse can be felt at the wrist and also in the superficial temporal.—29th: Wound dressed to-day; thoroughly aseptic; tube removed, and drainage effected by a strip of antiseptic gauze carried to the bottom. This being the first occasion of exposure of the aneurysm since the operation, I found that pulsation had returned in it, and that a current of blood still continued through the sac. The force of pulsation would be represented by an estimate of about one-half of that previous to operation. The early reappearance of a pulse in the radial and superficial temporal arteries had led me to expect this, and rendered it probable that, in spite of the apparent tightness with which the ligature was drawn, a chink existed between the folds of the crumpled-up artery through which the direct current continued.—31st: Wound dressed: thoroughly aseptic. Pulse 96; temperature normal; respiration 20. I may say now that this condition was maintained throughout, the patient kept absolutely free from fever or constitutional disturbance, and the wound aseptic till the final hæmorrhages necessitated a discontinuance of the dressings; these were changed about every third day. The pulsation in the aneurysm was slightly less than on the previous occasion, and in the radial artery was still further diminished. I hoped to favour the process of consolidation and cure of the aneurysm by immobilising the arm to the side, but though his pain and suffering were materially better than before operation, he was rather intolerant of this, and

Digitized by Google

it could not be carried out very effectually.—April 5th: Has had rather more pain again, for which the use of morphia was resumed. Aneurysm harder and smaller. Pulsation distinctly less; radial pulse almost imperceptible; temporal pulse increasing.—8th: Aneurysm still harder and smaller. There appears now less doubt about the object for which the operation was undertaken being accomplished if he should recover from its effects.—10th: A stain of blood looking a day or so old was seen for the first time on changing the dressings.—11th: Late at night a sharp hæmorrhage occurred, which was stopped by plugging the wound.—12th: Several small hæmorrhages took place every few hours, and were controlled by pressure. Patient kept well under morphia.—13th: Late at night another general hæmorrhage.—14th: Died in the evening.

Necropsy.[1]—Part of the incision was firmly cicatrised; the unhealed part opened into a cavity containing clot. The walls of this cavity were well consolidated, and at the bottom was the artery, on which the knot of the ligature could be felt. The aneurysm was of much larger dimensions than appeared on the surface; it completely filled the upper aperture of the thorax, bulging into this cavity; it lay against the spinal column, and had absorbed and eroded almost quite across the bodies of several of the vertebræ; it was quite inseparable from the column. The cords of the brachial plexus were flattened out behind the tumour; the internal jugular and subclavian veins were collapsed and flattened in front of it. The aneurysm sprang from the upper and back part of the artery. The mouth of the sac was very large, extending from within half an inch of the commencement nearly to the termination of the artery, so that the whole of the second, about half of the first, and a considerable portion of the third stages of the vessel were occupied by it. All the branches of the artery were in this area and opened into the aneurysmal sac. The remainder of the first portion of the vessel was of large size and flattened out in front of the sac, to which it was adherent. The aneurysm contained a large central mass of passive clot. Some portions were lined with old fibrinous layers to the depth of a quarter of an inch, and within these and also incorporated with other parts of the sac wall was a less firm coagulum. Elsewhere, and particularly near the large mouths of entering vessels, the interior appeared as a serous lining. The arch of the aorta and innominate were vessels of large dimensions, but without local or fusiform expansion. They contrasted markedly with the exceptionally small size of the left common carotid and subclavian and of the right subclavian beyond the aneurysm; the latter was much reduced in size. The aorta was thickened and atheromatous; the innominate also thickened and fibroid to a less degree. The position of the ligature was marked by a deep constriction almost exactly in its centre; the structures over the ligature were solid and organised, except at the knot, which was exposed; there was no purulent infiltration. The ligature still retained a firm hold on the vessel; one or two of the threads were partially absorbed and softened, but others scarcely changed. The knot, unfortunately very large and hard, was quite unaltered. Under the knot, in the front of the vessel and in the line of a fold or bend of its wall, was the obvious source of the hæmorrhage, in the form of a ragged hole about the size of a small pea; this opened into the vessel on both sides of the ligature. The further appearances were interesting and instructive in view of the debatable questions surrounding the use of animal ligatures. The wall of the innominate was thickened on each side of the ligature, the thickness gradually decreasing away from it. With the exception of the hole corresponding to the knot, no part of the arterial wall was injured or divided, though under the ligature itself the wall was thinner than elsewhere. The inner coats were intact. It was obvious that a small chink remained between the crumpled-up folds of the vessel, the remainder being occluded by adhesion of the inner coats. The chink was closed by a moderately firm clot; a similar clot, with conical end, extended along the distal side of the artery nearly to the bifurcation. The clot was only slightly adherent to the interior of the vessel, except under the ligature, where the adhesion was more firm. The hole in the wall of the artery having been closed, it was shown, by injecting water, that the vessel was wholly occluded at the seat of ligature. On the heart side there was a thin diaphragm of clot with a conical end, but it extended a very inconsiderable distance. As the bulk of the hæmorrhage no doubt occurred here, some of the clot may have got carried out during life. The walls of the common carotid were thickened, its cavity much contracted, but free from clot. There was free communication between it and the subclavian.

The observations which I submit on this case will be very brief. Into the general history and merits of the operation I do not propose to enter. Mr. William Thompson has recently handled this part of the subject in a complete manner,[2] and the grounds on which he defends and justifies the operation in suitable cases appear to me to be thoroughly sound. His own case, which is reported in his able and exhaustive paper, and which so nearly obtained success, goes far in support of them. I certainly do not think that, on the experience of the old methods of ligature, we are to regard the subject as a closed book not to be reopened. In dealing with this particular case I was not unmindful of the alternative courses. I had satisfied myself that medical treatment would be unavailing, while the severity of the patient's suffering rendered it most undesirable to abandon the case altogether. My reason for selecting this operation was simply its directness and certainty of action, and the belief that in it alone lay any hope of cure. I at once eliminated from consideration such methods of treatment as galvano-puncture and introduction of foreign material, on the ground that, from what I have read and seen of them, they are exceedingly fatal, while their value as a means of cure is almost problematical. Proximal pressure was impossible, the aneurysmal sac lying behind the first part of the artery. Amputation at the shoulder-joint needs, I think, more to recommend it than the hitherto limited experience of its use affords us before a surgeon will strongly urge such a serious mutilation on a patient. The distal ligature might have been tried, and could I have realised beforehand the condition of the artery it is quite likely this would have been the case. However, the vessel was fully exposed before I was aware of its state. There was no physical sign in the chest to reveal it, and the pulsation in the episternal notch was clearly that of the common carotid displaced by the tumour. Moreover, it appeared from the position of the tumour and the absence of a bruit that the mouth of the sac was of large size, and included just that portion of the vessel most occupied by large branches. Consequently I entertained but little hope of any backward development of a thrombus and a cure in this way. The post-mortem examination verifies the truth of this. When the artery was exposed the condition was obviously very unfavourable to success. I could see there would be increased difficulty in stopping pulsation and unusual risk of rupture of the artery, but I did not feel called upon to abandon the operation and close the wound, as so large a share of the operative risk had already been surmounted, and the vessel, though large in size, showed no local or fusiform expansion. I regarded the dilatation as in great part due to the resistance of the aneurysm beyond. The fact that I was unable to complete the ligature with the material originally intended may be matter for regret. The subsequent history and the post-mortem appearances show that if a knot could be avoided a different result was possible, even on a vessel so unfavourable. But I confess that the case would scarcely have been a fair one as a test for the material, and I quite anticipate that Mr. Barwell would not contemplate its application to such a vessel. In explanation of the breakage, I think it fair to say that the ligature was not only submitted to an exceptionally severe strain, but had probably got damaged in its dry state. The use of silk, or of any material which, though having the advantage of unlimited strength, must necessarily cut through the vessel and be cast off by ulceration, was out of the question. In employing catgut, sufficient had to be used to bear a good strain in tightening, to last a considerable time without absorption, and to maintain the integrity of the arterial wall. To gain all these advantages I used a cord of five or six medium-sized threads laid side by side, and as a material like this requires very careful tying to secure it, I felt it prudent to make a third knot. This knot, lying on a fold of the vessel, was, by its hardness and resistance to the forcible pulsation, the immediate cause of rupture of the artery.

In undertaking the operation, I entertained the greatest confidence, as I do now, in the value of the animal absorbable material for ligature, of the strict antiseptic condition of the wound, and in the principle of maintaining the integrity of

the arterial wall by the flat ligature so ably advocated by Mr. Barwell. It is on the latter of these points that opinion seems to be most divided. Should the arterial coats be cut through or not? I do not think we need seek to give one uniform answer to this question for all cases, but that it may wisely vary for different circumstances. With vessels of secondary size, in positions where the strict antiseptic condition of the wound is pretty sure, and, above all, where early deep union of the wound can be effected, a simple round cord of absorbable material (ordinary catgut), tied so as to divide the walls, leaves little room for improvement. There is in the latter point an additional security for permanent occlusion of the vessel. But it is well known that if the wound inflames and suppurates, the advantages of the animal ligature may be forfeited by solution of continuity of the vessel. It is to be recognised that the wound after ligature of the innominate is ill adapted for early union, and difficult to keep antiseptic. Though I was successful in securing the latter point in this patient, I found that the bony framework of the chest prevented deep apposition of the parts, and that a considerable cavity resulted in spite of graduated and elastic pressure applied to that end, as recommended by Mr. Thompson in the paper referred to. There can be little doubt, therefore, about the importance of the principle of maintaining the integrity of the arterial wall by the flat ligature in the case of the innominate artery. That an artery ligatured in this way becomes permanently occluded has been amply proved by Mr. Barwell's cases, and by those of Lister, Thompson, and others; it also seems that the existence of a chink at the point of ligature permitting a direct current of blood is no bar to the process. On this latter point I think the post-mortem appearances in my case bear in an interesting manner. They show that such a process of occlusion was in actual progress, though to an inconsiderable degree. When I found that pulsation had returned in the sac and in the radial and temporal arteries, I inferred that this was wholly due to the direct current past the ligature, and I seriously entertained the idea of reopening the wound and replacing it. Then, as the pulsation in the sac and the radial subsequently diminished, it appeared as if occlusion were gradually being effected by coagulation at the ligature, and there seemed increasing likelihood of the aneurysm being cured if the operation were survived. But the pulsation was still going on at a time when, as the necropsy shows, there could be no direct current past the ligature, so that it appears as if a good deal of this pulsation was due to the current of blood into the sac from the mouths of the large vessels opening there and from the common carotid. This fact, with the comparatively little change effected in the aneurysm, leave it still open to doubt whether the object for which the operation was undertaken would have been accomplished had the patient lived. The collateral circulation might have proved too direct and free.

ABSCESS OF THE SPLEEN OCCURRING IN ENTERIC FEVER.[1]

BY ROBERT S. ARCHER, B.A., M.B.
PHYSICIAN TO THE NETHERFIELD FEVER HOSPITAL, LIVERPOOL.

ON assuming duty at Netherfield Fever Hospital towards the end of last October, I found a boy, aged fourteen years, suffering from what appeared to be an intercurrent relapse or recrudescence of enteric fever. He had been admitted to hospital on Oct. 5th, 1885, under the care of my colleague, Dr. Dunbar, with a history of illness of two days' duration, which commenced with anorexia, vomiting, and rigors. His throat is reported to have been sore, and the tonsils superficially ulcerated. He, as far as I could ascertain, presented none of the common signs or symptoms of enteric fever; in fact, I believe he was sent to hospital as suffering from scarlatina, which was doubtless owing to the slight throat symptoms and a doubtful evanescent red rash. The temperature, which had been febrile since his admission, became normal on Oct. 18th, or about the sixteenth day of apparent illness. It remained normal until the 21st, when it again became febrile, and remained so till the patient's death on Nov. 1st. Oct. 24th was marked by slight pain along the course of the lower ribs on the left side, which was thought might have been due to pericarditis or pleuritis. However, careful examination failed to detect the existence of either of these conditions. On Oct. 26th the left hypochondriac pain became more marked, and on the evening of the following day there was slight general abdominal tenderness. The next twenty-four hours was marked by vomiting, intensification of the abdominal tenderness, and increased tympanitis, especially manifest along the course of the transverse colon. All these signs became more painfully apparent during the next three days, and there was superadded a certain amount of stupor and low muttering delirium. The patient died early on the morning of Nov. 1st apparently from peritonitis, due, as was thought, solely to perforation of the intestine.

At the necropsy (made about ten hours after death) there was fairly marked rigor mortis and considerable emaciation. The abdomen was generally and equally distended, and there was distinct general purulent peritonitis. The omentum and coils of the intestines were loosely held together by layers of yellow puriform lymph. A large quantity of yellow fluid, which had evidently escaped from the intestines, occupied the depending portions of the abdominal and pelvic cavities. The intestines contained some yellow semi-solid fæces. There was a perforation situated about a foot and a half from the ileo-cæcal valve, occupying the base of a cicatrising ulcer. Several of Peyer's patches were observed to be ulcerated, quite free from sloughs, and evidently in process of cicatrisation. The long axis of the ulcers was usually transverse to the course of the intestine, owing, I suppose, to the fact that cicatrisation had commenced from each end, and not laterally. There was a mass of almost entirely cicatrised ulceration in the neighbourhood of the ileo-cæcal valve. The liver was enlarged and pale. The spleen was enlarged, and generally soft and congested. Its convex surface was covered by a more or less uniform layer of yellow puriform lymph. In its upper part, and under the surface of its external aspect, was an abscess which would contain a large-sized walnut. This collection of pus had ruptured into the peritoneal cavity. The lungs were found to be hypostatically congested, but otherwise healthy. The pericardium contained a considerable quantity of clear, straw-coloured fluid. The heart was healthy.

Remarks.—Abscess of the spleen, a rare affection under all circumstances, would appear to be, contrary to what might be expected when we have regard to the fact that this organ is always affected to a greater or less degree in enteric fever, of very infrequent occurrence in this disease. Murchison's vast experience gives only two cases, both of which died, in what appeared to be a relapse, from general peritonitis, and he mentions five others from other authors. A considerable number of necropsies on the bodies of patients dying of enteric fever at Netherfield Fever Hospital during the last five years supplies only this single example of splenic abscess. In November, 1883, Dr. Coates showed at the Calcutta Medical Society a boy aged four with enlargement of the spleen, the result of malarious fever. An incision was made into an abscess, and about ten ounces of pus discharged.[2] As regards diagnosis, it may be mentioned that in this case the actual condition of affairs, as far as the spleen was concerned, was not determined clinically. But if in another case there were presented for our observation tenderness in the region of the spleen, pain under the left ribs, and a "creeping" peritonitis gradually extending from this as a centre over the abdomen, the existence of splenic abscess would be suggested to the mind; and, further, that the abscess had burst and set up general inflammation of the serous membrane would be quite a reasonable conclusion to arrive at. Although the boy was reported to have been taken ill only two days before admission to hospital, judging from the condition of the ulcers I am strongly inclined to believe he must have been going about with the fever on him for at least a week before the apparent onset of the disease. The reappearance of febrile symptoms after an apyrexial state of three days cannot be regarded as a relapse in the true sense of the word, but must be looked upon rather as symptomatic of the splenic mischief, just as in this disease, as well as in any other of the specific fevers, a continuance of the fever beyond the usual time, or a reappearance of fever, accompanied by manifest local lesions, must be regarded as purely symptomatic.

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF IDIOPATHIC ŒDEMA OF SCROTUM, FOLLOWED BY SLOUGHING OF ITS GREATER PORTION, WITH CELLULITIS AND SUPPURATION OF ABDOMINAL WALL; RECOVERY; REMARKS.

(Under the care of Mr. MORRANT BAKER.)

OUR readers will probably recollect the two cases of a similar description which are referred to in the remarks by Mr. Morrant Baker (see THE LANCET, 1885, vol. ii., p. 124). In both there was albuminuria, and the patients were considerably older (fifty-four and sixty-four) than the man whose case is recorded below. In one the symptoms had commenced a fortnight before he came under observation, and in the other seven days; both died, but the latter recovered from the local effects of the disease. The age of the patient in the present case, and the fact that he came under surgical treatment soon after the commencement of the symptoms, were greatly in his favour. For the notes we are indebted to Dr. F. Wigmore, late house-surgeon.

William P. H——, aged twenty-six, a cabinet-maker, was admitted into Harley ward on Feb. 16th, 1886, suffering from œdema of the scrotum. The patient stated that he was quite well until about **six weeks** ago, when he noticed a swelling in the right groin, which grew larger for about a week, and gave him a good deal of pain. It was opened at the Metropolitan Free Hospital, and, some pus being let out, he had no further trouble until the day before his admission into St. Bartholomew's, when he was suddenly seized with a severe pain in the scrotum, which swelled with extreme rapidity, and was very tender when touched.

On admission he was found to have a scrotum swollen to the size of a large cocoa-nut. It was very tense, and of a dusky-red colour with patches of dark purple. It presented all the appearances of approaching sloughing. The perineum was quite unaffected. The urethra also was entire, a No. 8 black catheter passing easily into the bladder. Four incisions were made into the scrotum where it appeared most tense, and a little blood and a good deal of serum escaped through them. The pain was much relieved. A charcoal poultice was applied. The temperature was 100·4°.

Feb. 17th. — The swelling has considerably diminished, and pieces of slough have come away. His temperature is normal. In the evening he was delirious and violent, and his temperature went up to 102°.

18th.—He obtained no sleep last night, in spite of chloral and bromide and the hypodermic injection of morphia. He appears much weaker, and his mind is very confused. The scrotum is quite lax, and most of the anterior part is occupied by a greyish slough. Urine: sp. gr. 1020; loaded with urates; contains a large trace of albumen, but there is no blood or pus. In the evening he became more delirious, and his temperature went up to 103°. His bowels have not yet been open.

19th.—Had a better night after the hypodermic injection of morphia. His temperature is 102·8°. He complains of great tenderness in the left groin, and great thirst. The skin of both groins is red, the redness extending up the left side to a considerable distance; poultices were applied over the inflamed areas; has been sick; pulse 132. He was transferred to the erysipelas ward in the afternoon. His temperature in the evening was 102·6°.

20th.—Had a much quieter night. His temperature this morning is 101·8°, and his pulse is 128 to the minute. The redness has spread up both sides, the left being the larger area. The sloughing of the scrotum has increased, and the discharge proceeding from it is very foul. The patient was put under chloroform, and several superficial incisions were made around the inflamed patches.

22nd.—The patient has improved. General condition better. Temperature 99·1°; pulse 136; respiration 48. The anterior aspect of the scrotum has almost entirely disappeared by sloughing, and both testes are exposed. The smell is still very foul. The erysipelas has diminished, and not extended beyond the incisions in any place. Charcoal poultices are applied to the scrotum, and large ones of linseed to the abdomen. The patient has developed a pleuritic friction sound, and some broncho-pneumonia over both bases. He is kept under a tent, with steam playing into it.

23rd.—Has not lost ground. Slept well. Temperature subnormal this morning; pulse 130; respiration 44. The urine contains no albumen now.

25th.—Is doing as well as can be expected. The condition of the base of the left lung is improving, but the signs have rather developed at the right base. The scrotum is healthier, and less foul. Erysipelatous condition nearly subsided. Temperature 99·2°; pulse 124, very soft; respiration 40.

28th.—The redness has completely disappeared. Odour from scrotum very offensive.

March 1st.—Feels slightly better. Temperature normal; pulse 120; respiration 40. A swelling has developed on the left side of the abdomen on a level with the umbilicus; it is red and distinctly fluctuating; it is also tender. There is an offensive blackish-green discharge from the scrotum. The patient was put under chloroform, and Mr. Baker made an incision into the swelling at its upper end and back part in the anterior lumbar region, when some dark, bloody, and very offensive discharge escaped. A long probe was then passed into the opening thus made, and the abscess cavity was found to track downwards and forwards to the pubes. Two other openings were made, the lowest just above the pubes, and drainage-tubes inserted. The poultices were continued.

3rd.—Seems considerably better this morning. A good deal of pus has escaped from the incisions of yesterday, and free drainage is maintained by the tubes. The discharge from the granulating scrotum not nearly so offensive as heretofore. Temperature subnormal; pulse 108; respiration 34.

8th.—Getting on well. Takes food well. Local conditions much improved.

10th.—Better in every way. Condition of abdomen very good; very little discharge. Tubes taken out; scrotum looks healthy.

15th.—Patient quite well up to 9 o'clock last night, when he became feverish, and his temperature went up to 101·6°. This morning he complains of headache and thirst. Edges of scrotal wound thickened and œdematous. There is redness over the right groin and extending a little upon the abdomen and over the buttock. Several incisions were made in the skin surrounding the patch.

16th.—The redness has almost entirely disappeared; the incisions seem to have controlled its spread. Scrotum healthier and less œdematous.

17th.—Redness less. Patient much better. Urine natural.

23rd.—Scrotum granulating nicely; dressed with boracic ointment.

April 21st.—Patient went to a convalescent home nearly well.

Remarks by Mr. MORRANT BAKER.—The foregoing case is an interesting example of a disease which is very apt to be confounded with extravasation of urine, and the notes may be compared with those of similar cases recorded in THE LANCET of July 25th, 1885. The diagnosis from extravasation of urine may be made, indeed, without much difficulty; but the superficial likeness in the two cases is very close. Apart from the history, the less marked hardness and tension of the scrotum, with the absence usually of any tense swelling in the perineum, in the erysipelatous cases will raise a suspicion of the nature of the disease, and the passage of a full-sized catheter without difficulty into the bladder will complete the diagnosis. In the present instance the extension of the cellulitis with suppuration to the abdominal wall above the line of Poupart's ligament is of much interest in connexion with the other points of similarity in the two groups of cases. The benefits arising, in what seemed a hopeless case, from free incisions of the abdominal wall, both in preventing extension of the disease and subsequently, with free drainage, in allowing the escape of decomposing fluid, which tracked from the scrotum nearly to the loin, were most marked. In many cases erysipelatous sloughing of the scrotum seems indicative of some profound deteriora-

Digitized by Google

tion of the general health. The patients whose cases were recorded last year both died; one within a few hours after admission into the hospital, and the other within a week or two of going to a convalescent home. The present case—a much younger patient—seems to be an exception, if one may judge from the apparently complete restoration to health which took place before his leaving the hospital.

MONTGOMERYSHIRE INFIRMARY.

A CASE OF PREGNANCY WITH ALMOST COMPLETE OCCLUSION OF THE VAGINA. (? CONGENITAL.)

(Under the care of Mr. C. E. MONRO.)

TOWARDS the end of October, 1884, C. K——, aged twenty-two, single, was brought by her mother, for the purpose of ascertaining the existence or non-existence of pregnancy. The mother, in common with the neighbours, had noticed her daughter's marked increase in size, and had arrived at the conclusion that she was pregnant. While strenuously denying this, the girl admitted that she had not menstruated since the beginning of April; menstruation had always been painful to her. The breasts were full, and the nipple and areola typical in appearance. She would not admit marked morning sickness, but indigestion, acidity, and flatulence were generally present, especially in the earlier portion of the day. It was endeavoured to ascertain the presence or absence of *balottement*, but about an inch and a half within the vagina an obstruction was found, which appeared to be complete—in fact seemed to form a "cul de sac"; apparently there was no aperture, but it was thought at one part of the obstructing membrane there was a slight depression. The urethra was suggestively dilated, admitting the index finger, and she had suffered from a certain amount of incontinence of urine. The opinion was then expressed to the mother that her daughter was about six and a half months advanced in pregnancy, but that there existed an obstruction which would necessitate an operation before she could be delivered. At the same time she was recommended to send the patient into the infirmary. It was then ascertained that when she was two years of age a boy had pushed a pointed stick into the vagina, causing laceration and hæmorrhage. When taken to a medical man, he expressed the opinion that "the injury might cause future trouble."

On admission she was examined with a speculum, and by means of a probe a minute aperture was discovered, just admitting an ordinary probe; by cautiously pushing it some distance above, the cervix could be felt. It was proposed to defer any operation till the child was viable, which would be about the second week in November.

Nov. 12th.—Assisted by Dr. Gowan and Mr. W. B. Ray, having first placed the patient under chloroform (before which both Dr. Gowan and myself detected the fœtal heart sounds to be 144 to the minute, the mother's pulse being 72, though the patient still persisted that she did not feel any fœtal movements, and that she was not *enceinte*), Mr. Monro proceeded to divide the obstruction with a hernia knife through a speculum from before backwards, the blunt-pointed knife being pushed through the minute aperture above mentioned; the incision was somewhat limited, the rest of the tissue being broken down with the fingers. The hæmorrhage was inconsiderable. The os uteri was then felt high up, with the fœtal head presenting. The vagina was washed out with permanganate of potash solution, and a Barnes's hydrostatic dilator (medium size) introduced; after the lapse of twelve hours this was removed, the vagina again syringed out, and the dilator reintroduced. This treatment was persisted with until the full-sized dilator had been brought to bear upon the still somewhat constricted portion of the vagina.

After a day or two it was deemed advisable to bring on labour; the os was dilated, the membranes ruptured, and a dose of ergot given. A fair labour followed, and, without any unusual difficulty, a moderately nourished child was born, weighing five pounds and a half, which survived its birth several hours.

Remarks by Mr. MONRO.—My reasons for heading this case "? congenital" are—1. That the slight injury in childhood was to the vulva or hymen (or is it possible that the obstructing membrane could have been the hymen abnormally placed and persistent?). 2. The appearance and feel of the tissue divided was that of a musculo-membranous structure similar to that of the vaginal wall, and by no means *cicatricial* tissue. If the case had not presented itself when it did, it would have been a critical complication at term, with the descending head pressing upon the obstruction. She was discharged from the infirmary at the end of three weeks, but was treated as an out-patient for incontinence of urine, from which she recovered. I ascertained that the vagina had again contracted so as to admit my index finger with difficulty, and then strongly cautioned her against running the risk of becoming pregnant again. My advice does not appear to have been taken, for I was informed that two months after leaving the infirmary she was married.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Report of Albumen Test Committee.—Aneurysm of Hepatic Artery.—Treatment of Nævus by Excision.—Suppuration in Mastoid Cells, with Thrombosis of Lateral Sinus and Septic Embolism.—Simultaneous Inflammation of Serous Membranes.

THE last ordinary meeting of this Society was held on the 28th ult., Sir Henry Thompson, Vice-President, in the chair.

The Albumen Test Committee presented a report of the work accomplished by them, which, according to custom, was received without discussion. In it the committee briefly reviewed the various modes of urinary testing for albumen in common use, and compared in turn Dr. Oliver's test-papers, Dr. Johnson's picric acid method, the potassio-mercuric iodide and acid, Dr. Pavy's pellets, the acid brine method, picric acid and brine, the acetic acid, and the nitric acid methods. The portability and delicacy of reaction of Dr. Oliver's papers were strong recommendations, but, apart from the question of easy carriage and compactness, the committee considered that nitric acid was most reliable and delicate. All the methods were said, however, to be respectively useful for the determination of the various proteids that might be contained in urine.

Dr. R. CATON read a case of Aneurysm of the Hepatic Artery. Only ten cases were believed to have been placed on record in European and American medical literature. The patient, a man aged forty, was admitted on Aug. 8th into the Liverpool Northern Hospital. He had had an attack of pain in the right hypochondrium accompanied by jaundice at Christmas, 1884; this lasted fourteen days, and was followed by complete recovery. Otherwise he had enjoyed good health till August 3rd, when the pain and jaundice recurred with great severity. He was admitted complaining of intense cutting pain in the right hypochondriac region; was in a state of partial collapse; the face and forehead covered with cold sweat; the pulse feeble and beating 92 times a minute; the temperature normal. He recovered under the administration of stimulants, warmth, and hypodermic injections of morphia. The hepatic dulness was found to extend 3½ in. in the mammary line, and percussion elicited tenderness over the liver. A rounded tender swelling, taken for the gall-bladder, was felt below the liver, a little to the left of the mammary line. The tongue was furred; skin and conjunctivæ yellow. The bowels acted with copious loose dark evacuations. The heart's dulness seemed increased; the thorax generally was hyper-resonant on percussion. The day after admission the patient was in a peaceful state. But the pain returned a day later and vomiting set in. On Aug. 11th the stools contained blood clots. This was the first time there had been any evidence of the presence of blood in the stools; it was now understood that the dark-coloured evacuation spoken of by the patient had consisted of altered blood. The diagnosis hitherto had been that of obstructive jaundice due to impacted gall-stones, but the occurrence of hæmorrhage cast doubts upon it. Two or three theories suggested themselves—viz., hæmorrhage from the bile duct, but the amount of blood was too great for such a source; or hæmorrhage from the bowel, having no special connexion with the liver affection; this seemed more probable, but was not a satisfactory explanation. Dr. Caton confessed that aneurysm of the hepatic artery never occurred to him. During the whole of Aug. 12th the pain was absent. Two stools were passed, both containing blood. The tongue was thickly furred. Temperature in the morning, 99·4°; and at 8 P.M., 102°. At 11.15 P.M. the house-physician was hastily summoned to the

Digitized by Google

ward, where the patient was found lying on the floor apparently dead. His face was pale and contracted, large drops of perspiration stood on his forehead, the pulse was scarcely perceptible, and he was for a few minutes only partially conscious. An ounce of brandy was administered, and half a grain of morphia was injected subcutaneously. The patient rallied for a time. He stated that sudden and intense pain had occurred in the right hypochondrium, and in struggling he had fallen out of bed. Considerable quantities of blood were vomited. He gradually sank, and died early in the morning. At the necropsy, an aneurysm about the size of a large marble was found in the hepatic artery; it had burst into the hepatic duct; the blood had passed back, injecting all the large bile ducts in the substance of the liver; it had also entered the gall-bladder, which was full of clots; and a large quantity of blood was also found in the duodenum, stomach, and intestine generally. Nothing noteworthy was found in any other organ.—Dr. GLOVER inquired whether a bruit had been detected over the tumour, and if there were any history of syphilis in the patient.—Dr. CATON replied in the negative to the first question; the notes would not supply an answer to the second.

Mr. R. W. PARKER read a paper on the Treatment of Nævus by Excision. He first read notes of a case of suppurating nævus situated on the back of a child aged ten months. It was of the mixed variety—that is, partly cutaneous and partly subcutaneous. When first seen it measured 2½ in. by 2½ in., and was considerably raised above the surface. The central (cutaneous) area was bright-red in colour; the subcutaneous (raised) portion extended several inches around this central one. It was stated that it had rapidly increased in size within the last few weeks. The nævus was excised through an elliptical incision, the edges of which were subsequently brought together with catgut sutures, and then coated with iodoform collodion. The child made a rapid recovery and left the hospital within three weeks. After removal the nævus was cut into and found to contain about an ounce of blood-stained pus. The interior of the sac was rough and corrugated, and divided into numerous loculi by strands of shreddy tissue running across the cavity. This case, the author said, was selected as being unusual on account of the suppuration within the sac; and because, on account of the size and of the largely subcutaneous nature of the nævus, it well illustrated the adaptability of excision as a means of treatment for this (mixed) variety of nævus. Mr. Parker divided nævi into three chief classes—the cutaneous, the subcutaneous, and the mixed variety, the last mentioned being by far the most numerous. For cutaneous nævi one of the simplest and most efficacious methods of treatment was the application of fuming nitric acid; for the subcutaneous variety, he advocated electrolysis or excision; for the mixed variety, excision was regarded as the surest and most speedy as well as the most radical method. The paper concluded with an analysis of 564 cases, and a description of the histological characters of nævus, microscopic specimens of which were exhibited.—Mr. GOLDING BIRD took exception to the sweeping statement that excision should be applied to all cases of nævus. Ligature was much to be preferred in cases which occurred in out-patient practice. A smaller scar followed the ligature than after excision, and the latter method was inapplicable to nævi of the scalp. In nævi below the lower eyelid and at the end of the nose the galvanic cautery alone could be used, and neither ligature nor excision could be adopted in these situations. Properly employed, the cautery left a minimum of scar and the least amount of contraction; cicatrisation being slow and cauterisation frequent at first. The cautery should be applied always at the circumference in commencing the treatment. He had lately employed this practice frequently.—Dr. WARD COUSINS said in some cases the knife was the best mode of treatment, but the worst in others. Some nævi disappeared under any kind of treatment. Nævi of the eyelids and nose should be cautiously and slowly treated; frequent and long-continued scarification was the method he himself adopted for these nævi. He approved of the extended use of the actual cautery, and never now made use of injections and never employed the ligature under any circumstances.—Mr. PARKER, in reply, said he had formerly had much experience in the use of the actual cautery. For nævi about the nose and eyelid he employed electrolytic needles. He advocated excision as being a radical cure, and because the after-treatment was so simple, especially when the edges of the wound could be brought well together.

Mr. VICTOR HORSLEY read a case of Suppuration in the Mastoid Cells complicated by Thrombosis in the Right Lateral Sinus, and Septic Embolism of the Heart and Left Lung, in which Recovery followed Trephining of the Mastoid Process, &c.; with Remarks on the Prevention of Septic Embolism in such cases. The patient, a female aged seventeen, was admitted into University College Hospital on July 31st, 1885. The history of the present illness showed that she had suffered from chronic otitis media since an attack of the measles at three years of age. This was aggravated by small-pox at thirteen years of age. Fourteen days before admission she "caught cold," and the parts around the right ear became acutely inflamed. The present state revealed total deafness in the right ear and extensive cellulitis, extending in front over the parotid, and above as high as the parietal eminence, while posteriorly it covered the mastoid bone and extended on to the occipital. The patient was evidently very ill, the temperature was 101°, and there was a foul discharge from the ear. Immediately on admission, Dr. Penrose, the house-surgeon in charge, made a free opening over the mastoid process. A quantity of fetid pus escaped, and the bone was found to be bare for some distance. On August 6th the patient's condition had become more unfavourable, and at midday the temperature was 105°. Mr. Horsley therefore considerably extended the wound, and found that the skull was bare over the lower and posterior fourth of the parietal bone, the whole of the mastoid, and part of the occipital. He trephined into the mastoid antrum, opening up the cells freely afterwards with a gouge, &c. He then cut away all the posterior wall of the external auditory meatus, converting the whole of the middle ear, mastoid cavities, &c., into an open gutter. The mastoid was full of horribly fetid pus. The whole wound was very thoroughly disinfected, and dressed with iodoform and iodoform wool. Next day the patient was drowsy, and the temperature exhibited a typical pyæmic curve. On the 9th—i.e., three days after the foregoing operation—the patient was seized at midnight with severe præcordial pain, dyspnœa, &c., lasting about half an hour. These symptoms of cardiac embolism were soon changed for those of pulmonary embolism, for the patient complained of severe pain under the lower angle of the left shoulder-blade, and here the physical signs of such a condition became evident. The patient, who had been treated at first with antipyrin, which produced violent and exhausting after-effects, was now kept perfectly quiet, and given large doses of Warburg's tincture. From this time she slowly gained ground, and convalesced completely about the end of September. In December the drainage-tube was left off. The suggestion was that thrombosis of the lateral sinus, if diagnosed (the symptoms were summed up in the original paper), could be successfully treated by very thorough clearing out of the temporal bone, &c. It became an open question whether under these circumstances it was not justifiable to ligature the internal jugular vein, since awkward complications arose from the very simple effect of detachment of portions of the septic clot.—Sir WILLIAM DALBY thought a procedure such as ligature of the jugular vein would require much careful consideration. It was important, however, to formulate rules for the opening of the mastoid cells. Many lives were sacrificed because this was too long delayed. These rules had been suggested by himself in former papers read before the Royal Medical and Chirurgical Society. When great tenderness existed, and a discharge was present through a ruptured tympanum, with pain and with high temperature, it was time to think about opening the mastoid cells. In one case symptoms of infantile palsy suggested the operation, the results being good. A special drill, devised for the purpose by himself, allowed of the easy and safe opening of the mastoid cells.—Mr. HORSLEY agreed as to the advisability of early opening of the cells; he would like to have discussed the question of opening the tympanum in cases of otitis.

Dr. HALE WHITE read a paper on Simultaneous Inflammation of several Serous Membranes. The patient, a girl aged nineteen, had never had rheumatic fever, but her father and mother had both died of heart disease. On admission she had some fever, abdominal pains, tenderness, constipation, impaired abdominal movement, slightly albuminous urine, and general pains about the body, especially the legs. The signs of peritonitis increased, but no cause for it could be made out. Two days after admission, the heart, which was normal on her coming to the hospital, showed increased cardiac dulness, extending upwards to the lower part of the second rib; there was a basic systolic murmur. The next day she was much worse, passing everything under her, and was sick. The breathing was entirely

Digitized by Google

thoracic. The cardiac dulness extended to the right of the sternum, and the cardiac pulsations were very visible over the whole area. Two days later there was a pericardiac trill present. In addition to the basic systolic, there was an apex systolic murmur. There was some dulness at the base of the right lung. A few days later some fluid was drawn off with a hypodermic needle from the right base. The signs of pericarditis became definite, and a pleuritic rub appeared on the right side. From this time the patient began slowly to improve; the cardiac dulness became normal; the dulness at the bases of the lungs disappeared, as did also the signs of peritonitis. During her convalescence the basic systolic murmur remained, but the apex systolic gave way to a presystolic, which persisted till her exit from the hospital, at which time, except for the presence of these murmurs, she was quite well. The examination of the sputum for tubercle bacilli and the choroid for tubercles gave negative results. During the severe part of her illness she was treated with opium, during her convalescence with iron and quinine. There can be no doubt that this patient had pericarditis, peritonitis, and pleurisy, and, in addition to this inflammation of three serous membranes, endocarditis, which led to a permanent presystolic murmur. The causes for inflammation of several serous membranes might be tubercle, Bright's disease, rheumatism, and pyæmia; or it may be that in certain exceptional cases the serous membranes have a tendency to inflame apart from any of the above causes. With regard to tubercle, it is certainly a possible cause in this case, for a boy was some years ago admitted into Guy's Hospital with pericarditis, pleurisy, and peritonitis. He got better and was discharged, and was readmitted shortly after with meningitis, which proved fatal, and it was then discovered that the pleurisy, pericarditis, and peritonitis were tubercular; but in the present case such an explanation leaves unexplained the endocarditis, and a careful examination of the sputum and choroid gave negative results. The slight albuminuria present on admission quickly disappeared, and the patient clearly had not got Bright's disease, and certainly also she had not pyæmia; and then, again, pyæmia rarely, if ever, caused peritonitis, apart from a spreading from some local suppuration. The late Dr. Fagge used to teach at the bedside, and had also mentioned in his recently published book, that sometimes he met with cases in which the three serous membranes now under consideration were inflamed at the same time apart from any cause that has been previously mentioned. The present may be an example of such a group of cases. Lastly, there is the rheumatic hypothesis. In favour of this is the fact that the patient's parents died of heart disease, that during the attack she developed endocarditis, and that the pains in the legs, which at the time were set down to her febrile condition, were severe, and might possibly have been rheumatic. The great objection to this view was that many who have had large experience deny the existence of rheumatic peritonitis, although now that it had been shown that Bright's disease would cause peritonitis, we must allow the existence of general causes for it. The case was put on record because it was of great interest as belonging to the very obscure group of inflammation of several serous membranes, and might perhaps, by the light of future cases, show that they were due to a rheumatic diathesis.

The following living specimens were exhibited:—Mr. Wainewright: Vertical Fracture of Head of Radius with Fracture of Coronoid Process of Ulna, treated by removal of the fractured portions. Mr. Godlee: A case of Myositis Ossificans. Mr. Battle: Charcot's Disease of Knee-joint in a woman aged forty-seven.

HARVEIAN SOCIETY.

Nerve-stretching for Leprosy.—The Albumens of the Urine.

A MEETING of the Society was held on May 20th, J. Hughlings Jackson, M.D., F.R.S., President, in the chair.

Dr. E. DOWNES read a paper on Nerve-stretching for Leprosy, founded on a large experience in nerve-stretching for leprosy and sciatica in Kashmir. Of forty-two cases recorded, thirty-two were well-marked cases of leprosy, and in all these anæsthesia of the lower extremities was an early and well-marked symptom. It was sometimes absolute and sometimes partial, being occasionally accompanied by absence of pigment or by tubercles, the latter occurring more commonly on the face, and often with severe neuralgia of the deeper parts. Ulceration commonly occurred in course of time, and especially in the feet, possibly beginning in some cases as a result of direct injury to the anæsthetic tissues, and often extending to complete destruction of the parts. Some of the cases recorded had lasted from one to seven years, and longer in two instances. The operation was done through a three-inch incision at the back of the thigh, the finger being hooked round the nerve and the limb lifted from the table. All the cases were benefited by the operation, and in some the ulcers healed completely and sensation was nearly restored to its normal state; the latter generally took place in the first few days. This success was fully appreciated by the patients, who repeatedly sent their friends suffering from leprosy to be similarly operated upon. The author observed that an exclusive diet of dried fish was not always an element in the production of the disease, many of his cases coming from districts where none was obtainable. He believed the ulceration to be due to peripheral neuritis, consequent upon some altered condition of the blood, for which the presence of bacilli might be answerable.—Dr. BUZZARD observed that these cases afforded direct proof of the relation of leprosy to affections of the peripheral nerves, and not to those of the spinal cord. The neuralgia and the immediate results of stretching were strong evidence in this direction. Although few English medical men had to deal with leprosy, he thought that a practical knowledge of the disease would lead to more thorough investigation of other forms of degeneration of nervous origin. Leprosy was at one time endemic in England, and he suggested that remnants and traces of it might still be existent in the form of localised atrophy or leukoderma.—Dr. DOWNES, in reply to questions, stated that in one of his cases sensation had continued good for two years; none others had been under observation for so long a period. He had obtained uniformly good results in nerve-stretching for neuralgia and sciatica.

Dr. ROBERT MAGUIRE read a paper on the Albumens of the Urine, the first portion of which will be found in our present issue.—Dr. BROADBENT, in acknowledging the extreme practical value of Dr. Maguire's observations, commented upon the clinical varieties of urinary albumen, sometimes associated with conditions of high arterial tension and sometimes with the reverse. Patients in the former condition were rarely in vigorous health, as suggested by Dr. Maguire, but always more or less ailing, and tonics did no good; these cases were generally associated with over-exertion or mental worry. The albuminous condition in early chronic renal disease was not always of the ordinary type.—Dr. SEDGWICK asked for information as to the relative amount of urea in the cases examined.—Dr. M. HANDFIELD JONES commented on the prognostic value of Dr. Maguire's experiments in deciding upon treatment in cases of albuminuria in pregnancy.—Dr. MAGUIRE warned the Society that his experiments must not be accepted as absolutely proven facts until they had been confirmed by further work. He had not estimated the quantity of urea.

ACADEMY OF MEDICINE IN IRELAND.

Causation and Treatment of Pneumonia.—Hyperpyrexia in Rheumatic Fever.

AT a meeting of the Medical Section on Feb. 26th, Dr. MARTIN (Portlaw) read a paper on the occurrence of a large number of cases of Pneumonia within a period of three months in a space about equal to half a mile square in that town. In only one instance did two cases occur in the same house, and in one of these the man was seized while working at a place six miles distant, where he had been residing for three weeks previously, and only returned home to be nursed. No person occupied in attending on or nursing a case was affected, even under circumstances particularly favourable to such a result. A certain amount of insanitary surroundings generally existed, and to this, aided by the particularly unfavourable climatic influence which prevailed, he attributed the outbreak, especially as in almost every instance the patient stated that the illness was produced by a chill caused by exposure to the peculiarly severe easterly winds which prevailed, when heated by exertion. Of the twenty-eight individuals attacked, twenty-six recovered. The treatment was based on old-fashioned lines: in the early stage, aconite, salines, diaphoretics, poultices, leeches; and in the advanced stage, occasionally flying blisters, and after their removal cotton-wool covered by gutta-percha paper, the patient's strength being supported all through by milk, beef-tea, eggs, and sometimes stimulants, but in very moderate quantities.

Digitized by Google

Dr. MARTIN tried quinine in some cases, and though perhaps with advantage, he was not in love with it as a remedy, preferring brandy when the temperature ran high, which agreed better with the patient and acted more speedily; but he stated that when one considered the very unfavourable circumstances under which he had to treat these patients in their own homes—seldom clean and amidst extreme dirt and poverty—his opinion on the action of a special drug like quinine could not be very positive or reliable.—Dr. H. KENNEDY did not look on pneumonia in any form as an infectious disease. In any acute disease rigor was the rule, and therefore he did not give any particular weight to its occurrence in pneumonia. He knew of an instance of nine out of twenty-one cows, all grazing on the same grass at Santry, dying of pneumonia; but the nine were Alderney cows, while the remaining twelve which remained healthy were of a different breed; in those cases he set down the disease to the difference in breed. Again, as to the epidemic character of pneumonia, he remembered, a good many years ago, having within three weeks nearly twenty in hospital in whom the upper lobe of the lung—generally the right—was attacked. The health of animals was no doubt deteriorated by bad sewage, but why the result should be pneumonia at one time and typhoid fever at another was a matter still *sub judice*.—Dr. WALTER SMITH said we must still confess to ignorance of what determined the outbreak in a large number of cases. He was struck with the remarkable contrast which the mortality of Dr. Martin's cases presented (only two deaths out of twenty-eight cases) as compared with that of the epidemic in Dublin. In Dr. Martin's cases it was of great practical interest to note that the pneumonia left permanent traces behind, as contradistinguished from the usual experience of acute pneumonia, which as a rule subsided, and the lung in many cases perfectly recovered, the patient being not a whit the worse—excluding, of course, cases of bad pleurisy—Dr. W. MOORE, referring to the contagiousness of pneumonia, instanced the case of a man, aged seventy, who died of it, and whose attendant, aged twenty-two, was attacked three or four days afterwards with the disease, from which he recovered.

Dr. A. N. MONTGOMERY, in the absence of Mr. W. Langford Symes, read his paper on Hyperpyrexia in Rheumatic Fever. The patient was a lady aged twenty-seven years, who, on a passage from Liverpool to Valparaiso, was attacked on board ship with all the symptoms of acute articular rheumatism. The temperature rose on the third day to 102°. She was put on the salicylate of sodium treatment, and in ten days the temperature was normal, and the patient was walking about free from pain and fever. However, after a convalescence of ten days she got wet through while in bed by the sea coming through the port-hole, and all her old symptoms returned, with a rapid rise of temperature to 106° within thirty-six hours. A full dose of twenty grains of quinine failing to have any effect in lowering the temperature, which continued to rise rapidly until the thermometer reached 108°, as a *dernier ressort* recourse was then had to the ice-pack, using towels wrung out of iced water, the application being gradually extended from the head to the lower extremities, and the patient being then rolled up in blankets, she was kept thus for ten minutes at a time. After the third and last application the temperature had fallen to 97·8°, thus making a sudden fall of 10·2° in the space of forty minutes, with marked relief to the head symptoms, as she completely lost her delirium, spoke rationally, and expressed her delight at feeling the icy cloths around her. The temperature after three days rose again to 102°, but never went higher; and from this point the pains diminished, and she finally landed in Chili thirty days after her first attack, free from any acute rheumatic symptoms other than a damaged mitral valve. The author remarked that though this plan of treatment was not free from danger from endocarditis, considering the weakened condition of the heart, still in this case, when other methods had failed to reduce the high temperature, it had succeeded, when if left alone the case must have ended fatally. He therefore thought that he was justified in using it.—Dr. W. MOORE believed there was no disease in which hyperpyrexia occurred less frequently than in acute rheumatism. He saw recently a young gentleman with this affection, and the temperature never rose above 101°; and very lately he saw a lady perfectly powerless, whose pulse was 120, while her temperature was normal. As to temperatures of 108°, 109°, and 110°, he never saw them. There was a form of rheumatism, which for want of a better name was called pyæmic, in which high temperature might occur.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

TUESDAY, JUNE 1ST.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

A LETTER was read from Sir Henry Pitman, resigning his appointment as member of the Council; and official notifications were read of the appointments of Sir William Gull as representative of the University of London, and of Sir Dyce Duckworth as representative of the Royal College of Physicians of London.

The PRESIDENT then delivered his opening address. He said that in this its thirty-ninth session the Council entered on its accustomed work with better hope than in past days, there being a fair prospect that the delay of the last fifteen years in granting further powers to the Council might come to an end in a way which might be considered a safe adjustment by the Legislature and the public. Having given a general outline of the new Medical Bill, he said that the new powers imposed no fresh duties on the Council, but enabled it to discharge with facilities the duties which hitherto it had not been able to fulfil. "The constitution of the Council," he said, "and even the individual members of the Council, remain the same, with the addition only of such fresh blood as the practitioners of the three divisions of the kingdom may in their discretion see fit to add to your body. Thus your educational work now in continuous progress need receive no check, but will obtain assistance rather from the cessation of a weary period of uncertainty. You can steadily proceed with that which is in hand without the fear, hitherto always impending, that your labour might be thrown away. For this result the medical profession and the public have reason to be grateful to the Government. I proceed to say briefly what is the work before the Council in this session. Primarily, it is still educational. Time was when it was hoped that some final resolutions would be arrived at, and that a royal road could be found for laying down rules for general, for scientific, and for professional education and examination. This road, after much exploration, is not yet discovered. But assuredly for the present we have data enough without further reports and inquiries. Do not students, not to say teachers and examiners, want rest rather than change? Do they not all need the assurance that their work, faithfully done, with the simple aim of making good practitioners, will be accepted without the endeavour to draw 'hard and fast lines' which will be frequently changed? Can it be that such details as the modes of marking the duration of time for written papers, and even the modes of distributing the papers, adopted by the great examining bodies, are to be any longer subjects of detailed and costly investigation? For myself, I feel bound to say that, should the Council deliberately believe it needful to see, for instance, that the mode of supervision during the writing of the papers is correctly carried on by any of the licensing bodies, the question arises whether the certificates of such institutions are any longer entitled to credit. But, in fact, inquiries of this elementary nature may, perhaps, be considered as completed by the publication of the series of papers now to be laid before you on the final examinations of the universities. These papers, together with the report of Mr. Teale, Professor Gairdner, and Mr. Stokes, substantially give a picture of the condition of all the licensing bodies in the kingdom up to the present date. It is not alleged that any body now wilfully makes default in examining, though it may be still possible that among large numbers of candidates some good are rejected, and also that through the skill of 'crammers'—or, to be more truthful, through the want of power to make examinations an unerring test of practical knowledge which cannot be evaded—some bad occasionally succeed. It is therefore proposed to refer the whole subject once again to a committee, which shall, at the next meeting of the Council, report on the whole subject of examinations. No one can reasonably doubt that each licensing body in the kingdom will accept recommendations deliberately made by the Council, and all the more if these recommendations are not often changed, and are not drawn out in too minute detail.

Digitized by Google

The Government Bill seems somewhat unnecessarily to dwell on the importance of appointing inspectors. The branch Council of England judiciously lays before you a brief but careful account of the course which visitations have taken in the last twenty years; it draws attention to the great increase of expense which has taken place in conducting them, and chiefly for this reason it recommends a complete revision of the regulations concerning them. In cordially agreeing to this proposal, I would not wish to be understood to express a doubt as to the expediency of the steps hitherto taken, nor as to the work of the visitors, whose zeal and success is appreciated by all. These steps have necessarily brought us by successive stages from a condition of educational chaos to one of more and more complete information. But I venture to repeat that, if there be any body which needs constant and minute inspection, from whatever cause, it is quite unfit to be entrusted with the function of licensing. Within the last quarter of a century the examination conditions have been greatly altered. The broad principles of medical education are now universally understood. If there be any bodies which do not, or cannot, adopt them, they are not entitled to public confidence. Personally, I do not believe that any such bodies now exist." After referring to several subjects to be brought before the Council, the President proceeded:—"It is clear that the machinery of medical education in this metropolis is about to undergo complete revision. The new buildings of the Royal Colleges, with their projected apparatus for education and examination, will, by aiding the unity and completeness of examination, aid the unity and completeness of teaching in the now numerous and separated schools of London. As the colleges in the old English universities have united in various ways for teaching purposes, so it is not impossible that the great medical schools may find an advantage in some form of union, both professorial and tutorial. Equalised instruction will in the present day generally produce higher and better organised instruction. We have to get rid of the old idea that all competition is downwards. The reverse is becoming the case. It is certain—and it is almost startling to say this—that some of the instruction given in London hospitals for the average learner is tenfold more detailed and more precise than in the student days of Hunter and of Brodie. Still, that it should be equal in all schools is impossible. But the clinical material in the hospitals, workhouses, and dispensaries is amazing by its vastness, as is too well known to philanthropists. Whether very minute teaching of this mass is valuable for the strong and independent youth, already trained and disciplined in scientific methods and university life, may, perhaps, be open to question. Strong men with large opportunity teach themselves. Students trained through really scientific methods will outstrip their less fortunate comrades at the bedside. But the general result throughout the whole kingdom of this movement must be a prudent regulating of the average education of the so-called pass-men. This is our real business. And then will follow of necessity the question, if it has not already been raised, of the recognition of such pass or training by title or degree. Then almost with certainty will be forced on this Council, in some form, the nature of 'higher titles.' The old traditional notion is not yet exploded that the titles of Fellow or Doctor, howsoever obtained, imply distinction. Is not the time now coming when an educated public will know that it is not the name, but the body that gives the name, which sets a stamp of honour or of nullity? The meetings of this Council will, under the pressure of new conditions, become a means of valuable interchange of thought on methods of study, by a skilled representative from every part of the kingdom, rather than meetings to inquire into examination details which are thoroughly understood by all examining bodies, and whose discussion will therefore be a thing of the past. The coming modes and the progress of the average teaching will, while science moves onwards, be a never-failing object of careful study." Having briefly expressed the regret of the Council at the loss of Dr. Storrar and Dr. Scott Orr, the President concluded:—"When, at the outset of my address, I spoke of the relief afforded to the Council by the thought that the constant threat of legislation might cease for a time, in consequence of the change which has been made in the constitution of the Council, I did not intend, certainly not from the chair, to express any opinion on the legislative policy of appointing persons to the Council in a particular manner. In this chamber, however constituted, whether we be many or few, there is highly complicated educational work to be done, and the will to do it. The present faith in large numbers of electors rather than in individual responsibitity may or may not be a passing political faith. On matters such as this, it is not for me here to speak. But of one thing I may remind you: under this Bill all the old local institutions are left unaltered to carry on their work. It rests with them whether their representatives on this Council shall labour for some supposed gain to any one division of the country and to their own special class, or whether, by here maintaining touch with their peers, they seek in the department entrusted to them the common weal of the Empire, at home, in India, and in the Colonies. If they steadfastly do this, they will continue to promote the health and comfort of large portions of mankind, sending out capable and upright men, to prevent, as well as to treat, disease in every part of the globe."

The Executive Committee was then appointed, consisting of Dr. Haldane, Dr. Quain, Mr. Marshall, Dr. A. Smith, Mr. Simon, and Dr. Humphry.

Sir Dyce Duckworth was appointed a treasurer in the place of Sir Henry Pitman, and Mr. Marshall was appointed chairman of the Business Committee.

The Finance Committee having been appointed, the President, in the absence of the public, made a statement of the facts that had come to the knowledge of the Council in regard to the discovery of Mr. Philp's defalcations. On the readmission of the public, the usual tables were received showing the results of preliminary education in 1885; the number of exceptional cases in 1885 under Clause 20 of the Council's recommendations on education and examination; the results of professional examinations held in 1885 for qualifications granted under the Dentists Act; also returns from the Army Medical Department, and the reports of the visitors of examinations held in 1885, with the remarks of the bodies visited.

Mr. MARSHALL moved, "That a committee consisting of five members, including one from each Branch Council, to prepare a summary of the reports of the Visitors to the examinations of the universities, and of the remarks by the bodies visited, now presented to the Council; and that this summary be submitted to the Council at its next meeting, together with such comments as the committee may think it desirable to make."

Dr. QUAIN seconded the motion.

Mr. MACNAMARA said he could not agree with the proposal. He considered that it would be a waste of time to appoint the committee, because the whole matter would have to be discussed by the Council. He deprecated altogether the Council shunting on to the shoulders of a few the duties that should be undertaken by the whole Council. The Council was established for the special purpose of discussing medical examination and education. Visitors had been appointed, their reports had been furnished and circulated to the bodies interested, and those bodies had sent in their answers, and no advantage could be gained by the appointment of a committee. The Council would be abdicating its functions and exposing itself to very just public censure if they were to give over into the hands of a committee that which it was their own duty to discharge. It might be said that members of the Council had not had time to master these reports, but he thought that would be a reflection as to the manner in which they were discharging their duties. The reports and answers had been sent to each member, and it was their duty to have studied them and be prepared to discuss them at once. Another reason why they should not be referred was that some of the remarks contained in the reports were anything but complimentary to some of the bodies that had been visited, and it was not just to such bodies that they should remain for perhaps twelve months longer under those imputations. In justice to those bodies the matter should be discussed forthwith.

Dr. CHAMBERS agreed that it was the duty of the Council to read through the reports, and to form an opinion upon them. He thought it would be impossible for a committee to draw up a summary without giving a colour to certain items, and, however convenient such a course might seem, would be a dangerous proceeding.

Dr. PETTIGREW objected, on the part of St. Andrews University, to keep the matter waiting a whole year till the preparation of a summary might prevent members from reading the entire reports.

Dr. DUNCAN thought that the main object [illegible]

Digitized by Google

by the reports had been already accomplished, and that it was necessary for the Council to give a judicial decision upon them.

Mr. TEALE considered that the reports ought to be summarised as proposed, and that the object sought should be, without any judicial decision, to ascertain broadly what could be learned from the picture brought before the Council as to the principles on which examinations should be conducted.

Dr. HERON WATSON said that the reports of the Visitors of the corporations were duly considered by a committee of the entire Council, and recommendations founded on them were issued, and he saw no reason why that course should not be adopted on the present occasion. It was proposed to postpone the matter to the next meeting, but who could tell when that would be, or how long the present Council would exist? The new Council might decline to take up a matter which it had not initiated.

Mr. SIMON objected to an indefinite delay, and thought that a small committee might at the present sitting deal with such parts of the reports as claimed judgment.

Dr. HAUGHTON opposed remitting the subject to the next meeting of the Council. He felt, with regard to his own body, that he was on his trial, and wished to be tried at once. He should have some very hot and lively remarks to make on the subject when it came up for discussion. (Laughter.)

Dr. A. SMITH preferred that the subject should be considered at once, and not kept in suspense.

Dr. STRUTHERS suggested that the committee also consider the reports of the Visitors of examinations of 1881.

Dr. QUAIN said that the reports were extremely valuable, and he should regret extremely if they were to be hurriedly dealt with at the present meeting of the Council. If each report were to be brought up and the Council were to act as arbiter in each case, the proceedings would be endless. He thought their consideration had better be postponed till the winter session.

Dr. HAUGHTON moved as an amendment: "That a committee be appointed consisting of five members, including one from each Branch Council, to prepare a summary of the reports of the Visitors to the examinations of the universities, and of the remarks by the bodies visited, now presented to the Council; and that this summary be submitted to the Council at this meeting, together with such comments as the committee may think it desirable to make."

Dr. PETTIGREW seconded the amendment, which, on being put to the Council, was carried.

On its being put as a substantive motion,

Mr. SIMON moved as an amendment: "That a committee be appointed, consisting of five members, including one from each Branch Council, to suggest for consideration during the present session of the Council such resolutions as they may think requisite in relation to the reports of the Visitors to the examinations of the universities, and of the remarks by the bodies visited, now presented to the Council; that other members of the Council desiring to suggest resolutions be requested without delay to send them to the committee."

Dr. MATTHEWS DUNCAN seconded the amendment, which after a short discussion was put and negatived.

The first amendment was then put as a substantive motion, and carried by nine votes to eight.

On the motion of Dr. HAUGHTON the committee was thus constituted: Sir Dyce Duckworth, Mr. Marshall, Dr. Haldane, Mr. Teale, and Dr. Lyons.

The Council then adjourned.

WEDNESDAY, JUNE 2ND.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The reports of the English, Scotch, and Irish Branch Councils, in regard to the methods hitherto adopted and to be adopted in the future in the visitations of examinations and the cost of such visitations, were received.

Dr. STRUTHERS moved a series of resolutions founded on the reports and the tables accompanying them; but on an expression of opinion on the part of several members of the Council that they should be postponed till the committee appointed yesterday had reported, he withdrew them.

The Council then resolved itself into committee for the consideration of reports by the Branch Councils in regard to the subject of elementary mechanics. The English and Scotch Branch Councils recommended the enforcement of the regulation of the General Council that the subject should be passed before registration; but the Irish Branch reported that, in its opinion, to insist upon compliance with the regulation would be impracticable and undesirable, owing chiefly to the want of appliances in the colleges and schools for teaching statics, dynamics and hydrostatics.

Dr. HUMPHRY moved: "That in accordance with the report of the English Branch Council, elementary mechanics of solids should form one of the subjects of preliminary examinations." Those reports, he said, indicated a desire that elementary mechanics should form one of the subjects of the preliminary examination. In order to ascertain whether it would be advisable to insist on this, he obtained information from various quarters. The Secretary of the Science and Art Department at South Kensington wrote that at the examination in theoretical mechanics, in May, 2375 candidates presented themselves. At the last local examinations at Oxford, 104 senior and 82 junior candidates took mechanics; and at the local examinations at Cambridge, 783 boys under sixteen took mechanics. It was therefore evident that a large number of students in England were taking mechanics, and in a very considerable number of schools there were means for studying the subject. But with regard to hydrostatics, a different state of things prevailed. Although there were numerous good elementary books on mechanics, from which students could obtain a knowledge of the subject, there was hardly any such book on hydrostatics.

Dr. HAUGHTON: Oh, yes; Galbraith and Haughton's. (Laughter.)

Dr. HUMPHRY said that at present the demand for a knowledge of hydrostatics had not been sufficient to induce anyone to bring forward a good elementary book upon it. Much, therefore, as he might desire for the purposes of physiology, that students entering the profession should have a knowledge of hydrostatics as well as well as mechanics, it seemed that at present that object could not be attained. The Irish Branch Council did not seem to have made that distinction. They sent to the various schools to ascertain what was the teaching in mechanics and hydrostatics, and the result came out that the two subjects were not by any means generally taught. Had the Irish Branch Council inquired separately as to mechanics, they would probably have obtained information similar to that received in England.

Dr. HAUGHTON said that elementary mechanics included hydrostatics.

Dr. HUMPHRY said the expression was commonly understood to relate only to solids.

Dr. PETTIGREW seconded the motion.

Dr. HERON WATSON objected to the exclusion of hydrostatics. It appeared from the report of the Scotch Branch Council that in Scotland there was no real difficulty in carrying out such an examination as had been recommended by the Council, including hydrostatics. If they departed from the repeatedly expressed opinion of the Council they would be creating great confusion in the minds of students, and introducing serious difficulties in the way of registration. As long as the subject of elementary mechanics was not enforced the subject would not be generally taught; but if the requirement were insisted upon the supply would soon meet the demand. He would move as an amendment: "That an examination in the subject of elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics, should be required as an essential part of the preliminary examination, and should be passed before registration on the Students' Register."

Dr. PETTIGREW asked and obtained permission to withdraw his seconding of the motion of Mr. Marshall, sharing, as he said he did, the views expressed by Dr. H. Watson.

Mr. SIMON said that the Council had so often affirmed its recommendation, that the continual reopening of the question reminded him of the labours of Sisyphus. It was not a question of enforcing the subject, but merely of recommending it as far as practicable. There was no good reason for cutting the subject in two, and thereby dislocating arrangements already made. Indeed, it was more important that students should be taught hydrostatics than that they should be taught solids and statics, and the importance of the subject had been over and over again affirmed.

Mr. MACNAMARA said he would second Dr. Humphry's motion; the regulation was compulsory and not merely a recommendation, and the Registrar of the Irish Branch

Digitized by Google

Council would not register any student as a medical student who had not passed in the required subject. It was because that Branch Council were impressed with the importance of the subject that they claimed to allow students to pass the examination before the first professional examination. It had been said that the demand would cause the supply, but he believed the result would be a sham examination.

Dr. HUMPHRY, speaking to the amendment, said that at the universities there were higher examinations in classics and mathematics than those required by the Council, but they did not include some of the subjects which the Council were endeavouring to enforce. They did not require hydrostatics, because it did not form, in England, a sufficient subject of school education. A few years hence there might be a change, but meanwhile he suggested a compromise. It was a great pity that the regulations of the Council should be such that the several great educational bodies should not be able to comply with them.

Dr. PETTIGREW thought that the Council would double back on themselves if they omitted hydrostatics as a part of the preliminary examination, and he hoped that they would see their way to simply reaffirm their regulation, for the supply would undoubtedly arise to meet the demand.

At this point, the hour having arrived when two medical practitioners (Wm. Turnbull and Robert Thorburn) had been summoned to appear before the Council, the debate was adjourned, and the Council resumed and considered the cases of the practitioners in private. On the readmission of the public, the President informed the Council that the Registrar had been instructed to erase from the Register the name of William Turnbull, Licentiate of the Society of Apothecaries, London, 1854, Member of the Royal College of Surgeons of England, 1859, convicted of manslaughter in an attempt at abortion, and sentenced to ten years' penal servitude; and also the name of Robert Thorburn, M.D. Edin., convicted of theft and sentenced to six months' imprisonment.

The Solicitor (Mr. FARRER) then read the opinion by Mr. Muir Mackenzie on a case in regard to the removal of qualifications from the Medical Register on the withdrawal of such qualifications by the licensing bodies. The effect of the opinion was that the removal could only be effected after the Council had been satisfied that the withdrawal of the qualifications by the licensing bodies had not been in consequence of the adoption of any particular theory of medicine or surgery.

Dr. A. SMITH said it would be in the recollection of the members that last year a letter was received from the Registrar of the College of Physicians, Ireland, stating that the name of Robert Locke Evans as Licentiate in Medicine and Surgery had been erased from their roll, and he thereupon moved that those qualifications should be removed from the Medical Register. An amendment was, however, passed postponing the consideration of the case until counsel's opinion had been taken as to the right of the Council to know the nature of the offence for which the name had been removed. He reported that decision to his College, who by resolution unanimously approved of his action in refusing to state the reasons. On Jan. 1st it was resolved: "That the President be authorised to give their representative on the General Medical Council a certificate in conformity with Section 28 of the Medical Act, that Mr. Robert Locke Evans' name was not removed for adopting or refraining from adopting the practice of any particular theory in medicine or surgery." He now produced the certificate, and moved: "That the qualifications of Licentiate in Medicine and Licentiate in Midwifery of the King and Queen's College of Physicians in Ireland, appended to the name of Robert Locke Evans in the Medical Register be removed by the Registrar."

Dr. BANKS seconded the motion, which was agreed to.

Mr. FARRER then read Mr. Muir Mackenzie's opinion on the case of Henry Francis Partridge, whose diploma in Dental Surgery, Royal College of Surgeons in Ireland, had been withdrawn, "because of his having, in violation of his undertaking given to the College, resorted to advertising in connexion with the Ladies' Dental Institution, South Kensington." The opinion was to the same effect as that previously read, and the Solicitor accordingly thought that the Council had power to remove the name from the Dentists' Register.

Strangers were again requested to withdraw, and on their readmission,

The PRESIDENT announced that the Council had passed the following resolutions: (*a*) "That the qualification of Licentiate in Dental Surgery of the Royal College of Surgeons in Ireland, appended to the name of Henry Francis Partridge, be erased from the Dentists' Register." (*b*) "That the name of the said Henry Francis Partridge be also erased from the Dentists' Register."

On the motion of Mr. MARSHALL, seconded by Mr. SIMON, counsel's opinions were referred to the Executive Committee with a view to the proposal of a standing order guiding the procedure in dealing with similar cases in future.

The Council again resolved itself into committee to continue the consideration of the motion and amendment relating to elementary mechanics.

Dr. CHAMBERS said he thought it very unlikely that the University of Oxford would be able to comply with the desire of the Council that hydrostatics should be made a subject of preliminary examination. The schools which fed the University were not able to introduce good teaching of it into their curricula. It was found that the higher physical sciences were not good gymnasia for the mental faculties in boys. These sciences, which involved the doctrines of classification, such as botany, general natural history, and chemistry, might be introduced into the curricula, but hydrostatics could not be made a compulsory subject.

Dr. HAUGHTON said that if the original rule of the Council were adhered to, the most highly educated students would cease registering. Would it not be better to go back to the regulation that the student might pass in elementary mechanics either before registration or before the end of the first professional year?

Mr. MACNAMARA said that it had been clearly demonstrated that it was impossible to give education in these subjects at present in the Irish schools; and an extra year was inflicted on the medical student, at a cost of £100, for not doing what it was impossible to do.

Dr. HERON WATSON thought that if the Council insisted on maintaining their regulation, the schools would soon be compelled to provide the requisite appliances.

Dr. PETTIGREW said that if mechanics were not passed at the preliminary, the first year's study in anatomy and chemistry would be seriously interfered with in Scotland.

Dr. STRUTHERS supported the amendment. Oxford and Cambridge had only to say, "Our entrance examination will require this subject," and it would be taught; or if some schools did not conform, intending students would go to others that did.

The debate was adjourned.

THURSDAY, JUNE 3RD.

The Council resumed the debate on the subject of elementary mechanics, and finally resolved, "That examination in the subject of elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics, should be required in the preliminary examination, and should be passed before registration on the Students' Register; but in universities with a prolonged curriculum, where the examination in mechanics required for a degree is taken at a more advanced period of study than before commencing medical education, the registration may be effected on having passed the examination in mechanics, and it should be the duty of the Registrar to antedate the entry to the period at which the preliminary examination was passed."

The Council then proceeded to consider the following motion by Dr. Haughton: "That in the opinion of the Council it is highly important to visit and report upon the methods of teaching required by the licensing bodies." Dr. Struthers was in possession of the meeting when the hour for adjournment arrived.

A fuller report of the day's proceedings will appear in our next number.

THE YORKSHIRE COUNTY FOOTBALL CLUB.—At a recent meeting of the committee of this Club it was resolved to apply the sum of £1000 to public charities of the county from the proceeds of the Challenge Cup Competition. The following are the sums awarded to the medical charities:—Leeds Infirmary, £200; Bradford Infirmary, £110: Clayton Hospital, Wakefield, £85: Halifax Infirmary, £85; Huddersfield Infirmary, £85; Hull Infirmary, £85; Dewsbury Infirmary, £70; York County Hospital, £60; Batley Cottage Hospital, £60; Keighley Cottage Hospital, £20; Bradford Eye and Ear Hospital, £20; Doncaster Infirmary, £10; Sheffield Infirmary, £10; Beverley Cottage Hospital, £8 10s; Harrogate Bath Hospital, £10.

THE LANCET.

LONDON: SATURDAY, JUNE 5, 1886.

THE Medical Bill still continues its precarious existence. If the Government survive a week or ten days, it may survive too; if not, it will share the fate of all its predecessors for the last fifteen years. On Monday night Sir LYON PLAYFAIR hoped to run it through Committee. We are sorry to use such an expression, but the duty of accuracy compels us. It is to be hoped that Parliament goes into other matters more thoroughly and with more knowledge of what it is about and of the principles which should determine legislation. But it is difficult to believe in the case of a Medical Bill that it approaches the subject with any such clear intelligence. It is a scramble between one corporation and another, or one university and another, or one division of the kingdom and another. When the Bill comes on in the small hours, most of the members have gone home to bed exhausted with the close air of the House and the excited debates of the period, and only a few interested members or obedient servants of the whips remain. When the division bell rings, most of them issue from the smoking-rooms as if they had been indulging in sleep rather than in tobacco. Some attempt at amendment of the fifth clause was made by the Irish members, but without any immediate effect. This is the clause that provides a new era for the Apothecaries' Companies, and which cynical critics say is the object of the Bill. But those who remained in the House in the small hours of Tuesday morning with any active purpose were divisible into two classes—those who wanted to get additional representation for their particular corporation, and those who perceived that the corporations have already too much power in the Council and have made it the powerless body which it is. The fight for more representatives of the bodies on the Council led to two divisions. It prevented the Bill getting through that night, which, in the present state of affairs, is very much like saying that it took away the last chance of the measure becoming law. The Bill proposed that Durham and Victoria Universities should have a joint representative, just as the Scottish universities have had since 1858. The first fight, begun by Sir HENRY ROSCOE, was to get a single representative for Victoria University. In this he was backed by Dr. FARQUHARSON, who, with characteristic honesty, announced that he supported Sir HENRY because he had a similar fight to make for the University of Aberdeen and expected to be backed by him in return. Sir HENRY magnified the claims and prospects of the Victoria University, though he could not maintain that it represented more than fifty medical graduates. He and all his supporters spoke very disparagingly of the Durham University and its methods. In spite of a spirited protest from Dr. FOSTER against increasing the already too large Council, Sir HENRY prevailed, partly we must say, from a most unfortunate want of firmness in Sir LYON PLAYFAIR. After this successful division came another discussion and another division on the claims of Aberdeen and St. Andrews to a separate member. Dr. FOSTER here was helped in his able opposition by Dr. TANNER and Sir JOHN LUBBOCK, and the motion was lost. But, as it is, we have the prospect of a Council with twenty-nine members, in which university representation will predominate. At present the interests stand thus: Crown five, corporations nine, universities ten, and direct representatives of the profession five. After the House had been treated to two discussions and divisions on the claims of universities, it was nearly 3 o'clock, the patience of members was gone, and progress was reported—which means that no further progress was made. Dr. FOSTER does not mean to let the matter rest where it is, but to try hard to get six direct representatives of the profession. We do hope that Sir LYON PLAYFAIR will give his hearty support, and will resist further attempts on the part of the bodies already over-represented.

IT is not long since we recorded some of the difficulties experienced by Australian colonies in the matter of the imposition of quarantine against cholera importation, the special instance being the emigrant ship *Dorunda*, which appeared to have contracted the infection after coaling at Batavia. Now, again, difficulty has arisen with the emigrant ship *Quetta*, which, after similarly touching at Batavia, was reported on March 29th to have arrived at Cooktown after having had on board during the preceding seven days several cases of diarrhœa and vomiting. She was, however, allowed free pratique; but the health officer at Townsville was prepared in advance and ordered to make careful inspection of her on her arrival. He telegraphed information to Brisbane to the effect that twenty-eight cases of colic and twenty-seven cases of diarrhœa and vomiting had occurred, and also that four persons had been poisoned by cocoa-nuts; adding that he had ascertained that the diarrhœa had been prevalent before, as well as after, touching at Batavia. But he recommended that the vessel should remain "in quarantine for observation" at Townsville. The Colonial Secretary, on the other hand, declined to sanction the proceeding, and hence the latest intelligence was to the effect that the *Quetta* was proceeding down the coast in the usual way, touching at the usual ports and landing passengers at each. Such a conflict of opinion and the setting aside of the advice of the medical officer of health on such a point are most unfortunate. Still, we cannot but feel that the difficulty arises mainly from the system which it has been decided to follow as regards infectious diseases on vessels touching at Australian ports. Where there is any substantial risk, or the fear of risk, the medical officer of health is bound to act on it; whereas the lay official, knowing but little as to the real risks, simply trusts to his common sense, and acts upon it. In all probability there was no cholera on board the *Quetta*. If so, there was no need for the detention. And if there had been cholera on board, anything more cruel than the proposed detention of the vessel under "observation" can hardly be conceived, for the result probably would have led to a considerable diffusion of the disease, and this under circumstances which would give the sufferers the worst chance of recovery. If instead of this so-called "observation," which under a new name retains the worst features of quarantine, the system known as that of medical

Digitized by Google

inspection had been adopted, no one would have been the worse for it; and, as it would have produced no avoidable hardship, the medical officer of health would doubtless not have found his opinion overridden. In short, no one could object to the landing and isolation of actual cholera cases, nor to a brief detention for the purposes of diagnosis of persons whose illness was such as to give rise to a genuine suspicion of cholera. But to detain a whole ship's crew and passengers, the majority of whom are in perfect health, merely to see if a certain disease prevails amongst a few of them, is a proceeding which is harassing to commerce and passenger traffic, and is a direct wrong to the healthy; because if the fears of those who detain the vessel are realised, it simply means that the healthy are to remain exposed to infection. The story of the *Dorunda* and that of the *Quetta* seem to imply that those who are responsible for the protection of public health against disease imported by sea in these colonies are halting between two opinions. The quarantine system advocated by the colonies is but a slight advance on the antiquated system of quarantine to which the Turk clings with tenacity; and the progress exhibited in favour of the system of medical inspection, as carried out in this country, is also so slight that it is but little akin to it; and the result is that there is no uniformity of practice, and that, although medical judgment is sought in the individual case, it may at once be set aside on other than medical grounds. The system resorted to is mainly responsible for the anomaly.

WE are glad to see that the movement for granting degrees to medical students in London, on the same conditions as those now existing at many of the universities, is making steady progress. A meeting of the Metropolitan Counties Branch of the British Medical Association, at which only one or two members were in opposition to the movement, showed clearly how strong is the feeling in its favour among London practitioners and teachers. It is so clearly a demand for simple justice and fair play, that, except for the fact of there being already a University in London, it is difficult to understand on what basis opposition could really be made. Sir ANDREW CLARK so forcibly and clearly put the demand and the reason for it, that practically nothing further remains to be said. "The curriculum is equal, the examination is equal, the age is equal, but the result is an unequal symbol of efficiency. It is a real practical grievance, which affects medical men in England, not only socially and materially, but even in their practice with their professional brethren, when the holder of a degree is held in higher estimation than the holder of the diplomas of the two Colleges." The professional examinations of the Conjoint Examining Board are admitted by all to be equal and in some respects superior to many universities granting a degree, and the teaching in the London schools is quite as good as at the universities, whilst the clinical teaching and the means for clinical instruction are far better. The difference to the average student is not in the curriculum of study, but in the reward for his industry. In the one case he gets a diploma, in the other a degree, and he quickly learns that the latter is more profitable and held in higher esteem by the public, and even by the profession, than the former. It is idle to suppose that the University of London will do anything to meet this just demand. The path on which it entered as an examining board, whose degrees were only to be attained by a select few, is one along which it is impossible for it now to retrace its steps. It may and should do much to facilitate the taking of its degrees, but the conditions on which they may be obtained can never be so altered as to make them attainable for the student of average ability and industry, and it is on behalf of these that the demand has been raised. No one suggests that a degree should be conferred on minimum terms, and the large majority of students come between the minimum and the maximum standard as fixed by the London University. An examination in general education of a higher class than at present demanded by the College of Preceptors, and another in elementary biological science, could easily be passed by such students, and then there could not be the slightest cavil at either their general culture or their professional knowledge. Sir GEORGE YOUNG has just taken an opportunity of publicly denying that the project of a Teaching University for London has "fallen through"; but if his scheme is to live it will only be by its fusion with this movement of the two Colleges, and thus gaining a first start in one Faculty.

THE state of the laryngeal muscles concerns the general physician as well as the neurologist and laryngologist. The last two numbers of THE LANCET have contained matter relating to the question. As the knowledge concerning these muscles does not appear to have become diffused throughout the profession, the present seems a favourable opportunity for a review of the subject, our aim being to place before our readers the actual facts and general tendency of knowledge. We shall not concern ourselves with those facts of laryngeal physiology that have but little present bearing on high pathology. Thus we are narrowed down considerably in our task, for the high laryngeal pathology of to-day has chiefly to do with the abductors and adductors of the larynx, or, more strictly speaking, with the openers and closers of the rima glottidis. The posterior crico-arytænoid is the chief abductor, and the lateral crico-arytænoid is the most important adductor. Both sets of muscles are supplied by the spinal accessory nucleus, which transmits its influences along the nerve fibres contained in the pneumogastric and recurrent laryngeal trunks. If all the muscles of the larynx be paralysed (complete palsy) the vocal cords are in the "cadaveric posture"—that is, a position of slight abduction from the middle line. During inspiration the vocal cords are separated by a considerable interval from one another. During expiration the cords come closer together, and in phonation are approximated still more. This close approximation or adduction is also seen when the recurrent laryngeal is stimulated by a strong electrical current—a remarkable result when we remember that the electrical stimulus must act equally, so far as its mere physical characters are concerned, on the nerve fibres of the abductors as well as on those of the adductors. The bearing of this fact will be understood later on.

Much discussion has taken place on the position of the vocal cords in disease of the neuro-muscular apparatus of the larynx, and the influences at work are so numerous that

Digitized by Google

this is not to be wondered at. But what there is to be known may be stated in a few propositions. If both the abductors are paralysed, the vocal cords are nearer together than in the "cadaveric posture"; they can still be brought closer together by voluntary action of the adductors, and after the abductor palsy has lasted some time, a secondary contracture of the adductors keeps the cords in a state of proximity almost equal to that of phonation. This abductor palsy may be caused by disease of the nuclei in the base of the brain; but palsy of one abductor may also be due to a general affection of the whole recurrent laryngeal nerve on the same side—a curious fact to be borne in mind with the equally interesting and in a measure complementary fact that electrical stimulation, as above mentioned, of the same nerve causes adduction of the cords. Indeed, this naturally leads up to the most interesting question in connexion with laryngeal pathology and physiology. Why should a general cause acting on the recurrent laryngeal effect adduction if it be of a stimulant character, and a tendency to adduction also if of a depressant kind? In a general way an answer to this problem is not difficult to discover. We may start with the assumption that the adductor apparatus is naturally stronger than the abductor system. A lowering of the power of both together finally leaves the adductor alone effective, whilst an increase, as by electrical stimulation, does but improve the adductor advantage. Now the difficulty is to know whether this difference between the two sets of muscles is of nervous or muscular origin, or whether it is related to both the nerves and muscles. The larynx is not without its parallel in possessing muscles and nerves of obviously different power. The generalisation made by Dr. FERRIER in *Brain* some seven years ago, to the effect that the abductors and extensors of the body generally are weaker than the flexors and adductors, may be mentioned here. Dr. FELIX SEMON'S anatomical and clinical proof, established by a large series of observations, that the abductors are more prone to paralysis than the adductors, is really of the same order as Dr. FERRIER'S generalisation, but the similarity in the names of the muscles enjoying power and relative weakness can perhaps hardly be regarded as more than accidental. The great truth to be recognised is that muscles of antagonistic action are not endowed with equal strength. This difference in strength shows itself in a greater proclivity to paralysis, as well as in a less ready power of recuperation. In the larynx progressive disease of the recurrent nerve has been observed by several laryngologists to show itself first by abductor palsy, which passes on to total palsy, with corresponding changes of position of the vocal cords, which are first in a position of slight adduction, later still more closely approximated, and finally assume the cadaveric posture. Whilst admitting that there is a general difference in the strength of the antagonistic apparatus, Dr. GOWERS has brought forward a strong argument[1] tending to show that a mechanical explanation would go far towards interpreting the reason why adduction is more powerful than abduction. "A force acts on a lever at greatest advantage when applied at right angles to the lever." The mechanical advantage at which the chief adductor acts, as compared with the chief abductor, gives greater power to the former, since it passes nearly at right angles, whilst the abductor passes at a very acute angle, to their identical insertion into the muscular process at the outer angle of the base of the arytænoid cartilage. This mechanical consideration may afford at least some explanation of the effect of a general under-action of the recurrent nerve in impairing "the effect of the abductors more than that of the adductors, just as the general over-action on electrical stimulation increases the effect of the adductors out of proportion to that of the abductors." In some cases of slowly progressive paralysis it has been observed that, notwithstanding a final total palsy, the vocal cords have been nearer together than in the cadaveric position. This has been explained by assuming that secondary contracture, having lasted a long time, had given rise to fibrotic processes, which had *set* the adductors in a fixed position, much as happens in the permanent rigidity of cases of hemiplegia and infantile palsy. Another interesting fact of laryngeal pathology is the establishment by Dr. FELIX SEMON and Dr. ORD of a progressive weakening of the abductor muscles in the laryngeal *crises* occurring in some cases of tabes dorsalis.

[1] See Diagnosis of Diseases of the Brain, p. 101.

UP to the present time nothing has transpired at the Medical Council calling for much notice or likely to affect either medical legislation or education. The President, in his Address, skims pleasantly and benignantly over everything that has been, might have been, or may be. Sir HENRY ACLAND is one of those happy men who see the good of everything that happens, and if things don't happen that he expects he is happy enough to see the good of their not coming to pass. The indiscriminate acceptance of whatever turns up may be a cheerful, perhaps a pious, frame of mind. But it is not one which excites our highest admiration. We could wish from a President more positive guidance, more decisive deliverances, more outspoken approval or condemnation. Let us take an illustration or two. A Bill is before Parliament adding seriously to the size of the Council, but not adding much to its power, importing the co-operation or sanction of the Privy Council into the work of the Medical Council. In the matter of the registration of foreign degrees, the Bill provides for the Privy Council overriding the Medical Council, and requires the latter to recognise and register a degree of which it may disapprove. The President, in his outline of the main features of the Bill, never alludes to the Privy Council. He expresses no dissatisfaction with the increased size of the Medical Council. In regard to the one good feature of the Bill, the addition of direct representatives of the profession on the Council, he has not one word of praise. The claims of the practitioners of the country to representation cannot any longer be resisted. They find at length spirited and earnest advocacy in Parliament. But it is disappointing and depressing to the profession to find so genial a man as the President of the Medical Council without a word of welcome for them or of hearty satisfaction at their prospect of admission to a Council of which they provide all the funds, and to whose deliberations they will bring a practical element which has been too often conspicuous by its absence.

One great feature of the present meeting is the presentation of Reports from the Visitors of examinations. It may

Digitized by Google

be remembered that gentlemen of eminence were appointed to visit all the universities in 1885. The reports are not yet available for criticism. They are understood to be interesting. They certainly have been rather costly. The bill is now before the Council, and reaches the large sum of £2225 9*s*. 4*d*. The average payment to each Visitor was £67 13*s*., and the average cost for each university visited (exclusive of printing) was £203. Considering the eminence of the Visitors, we do not think that there is anything excessive in their reward; but surely, if so much money is paid for Reports on the examinations of universities, we may expect them to be thoroughly critical, and to tell whether the universities are really doing university work. The profession will be apt to think that universities should not need such costly supervision, or that if they do need it, their whole system requires revision.

It is almost superfluous to add that the Medical Council has again collided with the subject of examination in elementary mechanics in connexion with reports from the Branch Councils on the subject. This is a yearly accident, and threatens, as on former occasions, to be a main occupation of the Council.

Annotations.

"Ne quid nimis."

THE REGISTRAR-GENERAL'S ANNUAL REPORT.

THE Registrar-General's forty-seventh annual report, which has just been issued, deals with the vital statistics of England and Wales for the year 1884. The interest in the main statistical facts for that year has been long since discounted by the summary of the figures in the four quarterly returns, issued with the report upon the last three months of that year on February 1st, 1885. The detailed report now published, however, gives information relating to the causes of death and the ages at death, which are absolutely necessary for the apprehension of the true import of marriage, birth, and death rates, measured by the proportion of those facts to the population at all ages. The introductory remarks to the present report discuss the causes of the remarkable decline of English mortality in recent years. The death-rate in 1884 was 19·6 per 1000, with reference to which it is remarked that "this is the fourth consecutive year in which the death-rate was under 20 per 1000, whereas in no single previous year since civil registration began had the rate fallen to that level." Pessimists have sought to ascribe the decline in the English death-rate to a "series of years of favourable meteorological character, and notably to the absence of excessively cold winters and excessively hot summers." This assertion is conclusively disposed of in the report before us, which points out that the "decline of mortality has been common to all four quarters of the year, and shared by them in pretty equal degrees; so that in order to give consistency to the suggested explanation, it would be necessary to assume a succession of years in which all four quarters alike—spring, summer, autumn, and winter—were marked by gradually improving meteorological conditions, an improbable supposition, for which there is no apparent warrant." It appears that English mortality in the four years 1881-84, compared with that in the thirty-three years 1838-70, showed a decline of 15 per cent. in the first quarter, 14 per cent. in the second and third quarters, and 11 per cent. in the fourth quarters of those years. Among other special points of interest dealt with in the report just issued may be noted the geographical and seasonable distribution of some of the principal zymotic diseases; and an exhaustive examination of the statistics of cancer mortality during the past thirty-five years, with especial reference to the recorded increase of that mortality and its geographical distribution, after due correction for the variations in the age and sex proportions of the population in the several counties of England. The results of this elaborate examination are admitted to be rather negative than positive, but it is urged that "the labour will not have been altogether wasted if it prevents incautious inquirers from forming hasty conclusions from rates that have neither been corrected nor based on a sufficient number of years."

THE STATUE OF HUNTER.

ON the 29th ult., a statue of John Hunter, "the father of scientific surgery," was unveiled in the new Museum at Oxford by Her Royal Highness Princess Christian, in the presence of a large assembly of spectators. Previous to the ceremony an address was delivered in the lecture-room of the Museum by Sir James Paget, who dwelt on Hunter's scientific curiosity and power of amassing facts, and the duties of a university to its students of science. Of this address we hope to give a report next week. An interesting account of the scientific movement in Oxford and the foundation of the Museum some forty years back was afterwards read by Sir Henry Acland, who concluded by paying an eloquent tribute to the interest shown by the Queen and the late Prince Consort in the establishment of science in Oxford, and indicating the propriety of the act about to be performed by their daughter, the Princess, to whose interest in medical science and in all means for alleviating suffering he referred. The statue, which was then unveiled, is one of five statues, representing heroes of science, presented to the university by Her Majesty. It represents the great *savant* standing with the legs crossed, and supporting himself on a pillar or post, with a remarkably keen and searching countenance. The statue is in soft stone, and stands upon a bracket against a pillar, near the entrance to the Museum.

SUCCESSFUL EXTIRPATION OF THE SPLEEN.

La Gazzetta degli Ospitali (May 23rd) reports a case from the surgical clinique of the University of Genoa in which Professor A. Ceci removed a greatly enlarged spleen. The patient, an imperfectly developed and very thin girl, aged seventeen, weighing 40 kilogrammes, and 1·40 metre in height, with very small pulse, had had an abdominal tumour from birth. The transverse diameter of the tumour was 34 centim., the vertical 23 centim., and the circumference about 64 centim. The anterior surface was smooth and convex, the margins sharp and fissured. The posterior surface presented a large lobe on the left. The abdominal walls were very flaccid, so that the tumour could be completely rotated vertically and transversely, and also be pushed into the left hypochondrium, whence, however, the respiratory movements soon caused it to advance to the front of the abdomen. The liver was in normal position. The enormous size of the floating spleen interfered with the patient's movement and nutrition, and was an occasional source of very severe attacks of pain, radiating from the left hypochondrium to the præcordial region and the left upper limb, and attended with violent dyspnœa and insensibility. Extirpation having been resolved upon, it was performed on March 20th, with strict antiseptic precautions. The incision in the linea alba from above downwards through the umbilicus was 23 centim. (9¼ in.) in length. On opening the abdomen, serious signs of suffocation compelled the

Digitized by Google

suspension of the operation for nearly thirty minutes. Anæsthesia having been commenced with bichloride of methylene, chloroform was substituted for it. A triple catgut and carbolised silk ligature having been applied to the pedicle, it was dropped in. The peritoneum was sutured separately. The abdominal walls were brought together by three metallic points, after Billroth's method. The splenic artery was larger than the subclavian. The whole operation, including the interruption, lasted an hour and a quarter. Violent delirium and nervous phenomena simulating angina pectoris soon followed. For two days the pulse could not be counted, and the respiration varied from 70 to 80 per minute. The treatment was by oxygen and nutritive clysters. The wound was first dressed on the eighth day, and almost the whole of the wound-tract suppurated. In spite of strict antiseptic treatment erysipelas supervened, and yet the patient recovered. On April 22nd (thirty-one days after the operation) her condition was reported as excellent, only a small superficial wound remaining. The extirpated spleen, with the contained blood, weighed 2400 grammes, equal to 37,036·8 grains, or 77·16 ounces. A courteous note just received from Professor Ceci states the patient is in good health; pulse 80; respiration 22; weight increasing rapidly; complexion florid.

HONOUR TO THE MEDICAL PROFESSION.

THE Queen has been graciously pleased, on the occasion of the celebration of Her Majesty's birthday, to sanction the following amongst other appointments. To be ordinary members of the Military Division of the Third Class or Companions of the Order of the Bath: Deputy Surgeon-General John By Cole Reade, Medical Staff, and Brigade Surgeon George Farrell, Bengal Medical Establishment. To be an ordinary member of the Civil Division of the Third Class or Companion of the said Order:—William Orange, M.D., Superintendent of Broadmoor Criminal Lunatic Asylum. Surgeon-General Michael Cudmore Furnell, M.D., Indian Medical Department, Madras, Surgeon-General with the Government of Madras; and Deputy Surgeon-General Alexander Morison Dallas, Indian Medical Department, Bengal, Inspector-General of Civil Hospitals, Punjaub, have been nominated and appointed to be Companions of the Order of the Indian Empire. The honour of Knight Bachelor has been conferred on the following gentlemen: Surgeon-General T. Longmore, Professor of Military Surgery, Netley Hospital, Dr. E. H. Sieveking, Mr. W. White Cooper, Dr. Douglas Maclagan, Professor of Medical Jurisprudence in the University of Edinburgh, and Mr. John Tomes. We regret to announce that since the publication of Her Majesty's intention to confer the above-mentioned honour on Mr. White Cooper his death has occurred, to the great sorrow of Her Majesty, whom Mr. Cooper had attended as oculist for upwards of thirty years.

SUDDEN DEATHS AFTER SEVERE EXERTION.

Two deaths have recently occurred which ought to serve as a note of warning to those who undertake severe muscular exertion without due preparation for the same. In one case the fatal results occurred during an Alpine expedition; in the other after a sharp row on the river; in both death was by syncope. It is probable that in each case, had the work been undertaken gradually and with some degree of training, instead of a fatal result ensuing, the bodily health might have been improved. Both of the deceased persons were of an age when degenerative changes in the muscular tissue of the heart or of the vessels would hardly be expected, and the syncope must have resulted from the sudden strain thrown on the cavities of a heart weakened previously by a long period of inactivity, and before the concordant action between the heart and great vessels had been established. This is always a danger when violent exercise is suddenly undertaken, and the mischief is of course greater in elderly persons than in young adults. Many middle-aged men who, at the commencement of their autumn holidays, after months of comparative inactivity, undertake without preparation some feat of Alpine climbing, or a long day's grouse shooting on the moors, lay the foundation of future heart troubles or aneurysm simply because they will not allow time for the concordant action between the heart and great bloodvessels to be established. In all cases where men are suddenly called upon to exchange a sedentary life for one of increased activity, they should consult their medical attendant as to the condition of their circulatory system. One instance is particularly recalled to us of a distinguished general practitioner, who had long been troubled with a spasmodic cough, which he thought proceeded from deranged stomach, and which a month among the Alps would soon put right. He started on his journey, but fortunately *en route* he travelled in the same carriage with a physician who was personally a stranger. During the journey the physician was struck with the character of the cough, and after a little conversation an examination of the chest was made, which resulted in the discovery of an aneurysm of the transverse aorta, which had escaped the patient's notice. Had he made any of his contemplated ascents he would have aggravated the condition, even if the attempt had not led to sudden rupture of the sac and immediate death.

NITRO-GLYCERINE.

IN the annual report just issued by Her Majesty's Inspectors of Explosives, it is stated that "it may be interesting to record that the use of nitro-glycerine as a medicine has for the first time been recognised in the British Pharmacopœa, and that the substance made up into lozenges and solutions is now rather largely and, so to speak, authoritatively employed in cases of angina pectoris, &c., for which purpose it has hitherto been irregularly employed for some years." We do not know what significance is attached by the Explosives Department to the word "irregularly," but it may be as well to point out that the nitro-glycerine has now been used in legitimate medicine and on well-established principles for the last six or eight years, and that it is not necessary for a remedy to find a place in the British Pharmacopœia to sanction its use in the treatment of disease. The report goes on to say that "this legitimised use of nitro-glycerine as a medicine has led to the question being raised as to the conditions as to which the same could be made and sold, and the Secretary of State has signified that it is not proposed to interfere with chemists manufacturing small quantities of nitro-glycerine for *bonâ fide* medicinal purposes; but that if it appears at any future time that the public safety is endangered by such manufacture, this statement is not to prejudice such steps as may then be considered expedient; and that as the maximum amount of nitro-glycerine contained in the tablets is very small, it is not proposed, for the present at least, to put any restrictions on their manufacture or sale, as it appears that a very large number of them would have to be treated to extract a sensible amount of explosive from them for practical purposes." This statement, cautious though it be, practically legalises the manufacture of nitro-glycerine; and all that is necessary in case of a prosecution will be for the prisoner to plead that he was making the explosive for medicinal purposes. It is further stated that "the question of scheduling nitro-glycerine, when employed as a drug in medicinal preparations, as a poison, is at present under consideration; and it seems desirable, having regard to the somewhat attractive forms—e.g., chocolate tablets—in which such

Digitized by Google

preparations are sometimes presented, that their sale and handling should be surrounded with the precautions which attach to poisons generally. The excessively narrow limits of quantity which is deemed prudent to authorise for a dose lends weight to this suggestion. The question has already been raised by the Department, and is at present occupying the attention of the Medical Department of the Privy Council, by whom it will no doubt be referred in due course to the Pharmaceutical Society."

ACTION AT LAW FOR ALLEGED TIGHT-BANDAGING.

AT the late Leeds Assizes an action was brought to recover damages by Mabel Moss, a minor, through her father as next of kin, from Dr. West-Symes, a surgeon living at Halifax. The allegation made by the plaintiff was that Dr. Symes had not used "fair, reasonable, and competent skill" in the treatment of a simple fracture of the clavicle, which the child in question had sustained. The main charge of malpraxis was that defendant had bandaged the arm over the elbow-joint whilst the limb was in an extended position, and that he then flexed it, with the result that gangrene supervened, necessitating amputation. It was further alleged that on the day on which Dr. Symes set the fracture he expressed the wish to see the patient after a week had elapsed. These charges were specifically traversed by the defendant. Two medical men called for the plaintiff deposed that in their opinion the gangrene was due to faulty bandaging. For the defence, Messrs. Wheelhouse, Pridgin Teale, Jessop, and McGill testified that it was quite possible for the arm to have been skilfully bandaged and for the swelling to have come on subsequently. If this were the case, there could be no doubt that the parents were careless in not noting the advent of the very pronounced signs of difficulty and arrest of the circulation; and, indeed, one witness, a chemist, said that the mother of the child admitted the latter had been in great pain, and had been rambling and talking at night, and that her finger-nails were black. This was said to have happened on a Thursday, and yet the mother expressed her intention of not taking her daughter to the doctor until the following Monday. There can be no doubt that had the apparatus not been applied gangrene would not have ensued, for the treatment of the fracture was not carried out until three days had elapsed from the date of the accident. The supposition that a splinter had penetrated or compressed the subclavian vein, or that the main vessels had been torn by the injury, could not therefore be entertained. But, as the judge remarked, the doctor would be less likely to depart from the precepts he had learned in his earlier days and afterwards carried out in practice, than the plaintiff to note the exact order in which the bandaging was effected in reference to the flexed or extended position of the arm. Very properly too, as we think, he laid little value on the evidence of the child. The verdict of the jury could scarcely have been different in the face of the opinion of such unimpeachable authorities as the gentlemen above named. Dr. Symes has our sincere sympathy, and doubly so inasmuch as he magnanimously declined to ask for costs. His character as a surgeon had been impeached, and he had rebutted the charge successfully. He cannot be blamed for employing the particular method (Desault's) of treating fractured clavicle, seeing that it is recommended by surgeons of the highest repute. We cannot help saying, however, that we prefer other plans, as being attended with less risks of gangrene. A modern authority has described Desault's plan as "classical, but clumsy and complicated." Nor can we entirely subscribe to Mr. Wheelhouse's assertion, as reported, that the axillary pad is essentially necessary. It does not form a part of Sayre's treatment of broken collar-bone, and yet we think that for children this is preferable to any other. It is certainly not desirable, much less necessary, to confine the patient to bed, as seems to have been suggested by one of the medical witnesses for the prosecution.

THE RETIREMENT OF DR. ORANGE, C.B.

IT is now close upon a quarter of a century since a great public want was removed by the erection of a central asylum for the reception of the criminal lunatics of England and Wales, instead of having them scattered all over the country in various prisons and county and private asylums. When Broadmoor was opened in 1863, Dr. Meyer and Dr. Orange, from the Surrey County Asylum at Wandsworth, were appointed respectively superintendent and deputy superintendent. Upon Dr. Meyer's lamented death in 1870 Dr. Orange was promoted by the Secretary of State to the vacant superintendentship. The success of his administration of this anxious and responsible post is too well known, both in this and other countries, to require notice in these columns. In 1882 Dr. Orange was unfortunate enough, while in the discharge of his duties, to be assaulted by one of the inmates (the Rev. H. J. Dodwell, who some years ago was found insane by a jury when tried for firing a pistol at the late Master of the Rolls). He received a severe blow on the head with a stone slung in a handkerchief, and we much regret to learn that the effects of this blow have necessitated the retirement of Dr. Orange from a post in which he has most efficiently administered a grave and responsible public trust. In the hope that the step might enable him to carry on his work at Broadmoor, Dr. Orange was last year, at his own request, relieved of the trying duties devolving on him as one of the advisers of the Home Office authorities in cases where capital crimes had been committed, and where the question of insanity arose. It is in this relation that the general public have to be especially grateful to Dr. Orange, for, with an exceptional experience on the subject, his scientific penetration, his sound judgment, and his shrewd common sense never failed to secure universal approval for his decisions on these momentous issues. The public will hear with satisfaction that Her Majesty the Queen has been pleased to decorate Dr. Orange with the Civil Companionship of the Order of the Bath in recognition of his eminent services. On the evening of the 31st ult. the officers and staff of Broadmoor Asylum presented him with a handsome silver salver "as a parting token of their personal esteem, and in grateful appreciation of his many acts of kindness." We congratulate Dr. Orange upon the successful results of his labours in the public service; he carries with him into his retirement our best wishes and those of the whole profession: and we trust that prolonged rest and freedom from official anxiety and strain will very largely, if not altogether, restore him to health.

A YACHTING HOLIDAY.

A WANT which must have been felt by many summer residents at the coast appears to have been met by the enterprise of Major Colwell of Portsmouth. This gentleman, we are informed, proposes to take on board of his fine yacht, the *Erminia*, a limited number of ladies and gentlemen at a moderate daily cost. The idea is not quite a new one, having already found practical expression in the voyages undertaken by the *Ceylon* and various coasting steam yachts. In the present instance, however, a salutary variation has been introduced by the employment of a sailing vessel for the same purpose. The example set will not, we hope, lack imitation. We have repeatedly spoken of the benefit which may

Digitized by Google

be derived from a holiday spent, not at the seaboard merely, but upon the sea. For men in fair general health, but fatigued with the cares of business or professional life, the combination of rest of mind and body with the freshest of pure air is a very happy one. The same might be said of convalescents from illness, who require only a bracing atmosphere to restore their general tone. Many invalided men from abroad would profit by the same wholesome exposure. It is understood, of course, that in each case the would-be sailor is jaded rather than ill, and is not peculiarly subject to sea-sickness. Under such conditions we do not doubt that he would equally gain in pleasure and in profit by the refreshing leisure of a yachting voyage.

PREVENTIVE INOCULATION IN YELLOW FEVER.

THE subject of inoculation for yellow fever, as practised by Dr. Domingos Freire, of Rio de Janeiro, was brought under the notice of the Société de Biologie of Paris at its last meeting. M. Rebourgeon communicated the results obtained by himself and Dr. Freire in December, 1885, and January and February, 1886. The weather during these months in Brazil was intensely hot, and yellow fever prevailed severely. Of 3051 subjects inoculated at Rio not one had died, whereas in the same districts and houses 278 non-vaccinated had succumbed to the disease. The number of the inoculated has now reached 6000, and not one of them has been attacked with the fever; and, what is more remarkable, severe cases inoculated in the second stage of the disease had all recovered. In reply to M. Brown-Séquard, M. Rebourgeon said that but few foreigners were inoculated, but yellow fever is at the present time creating great ravages among the Brazilians and mulattoes; the negroes even are being largely attacked, which is a rare occurrence; and the area of the disease was extending inland from the littoral. He explained that some specimens of virus sent two years ago to M. Cornil, and found by him to be worthless, had not been sent by Dr. Freire, but by opponents to his method. He had often inoculated himself, and was so convinced of the efficacy of the attenuated virus that he had frequently offered to undergo inoculation with the yellow fever itself. He presented a specimen of the vaccine to the Society for examination. In reply to M. Maurel, he said that he had met with yellow fever at an altitude of more than 700 metres, and had seen many cases among emancipated negroes, although less than among mulattoes, who were attacked in about the same proportion as the whites. M. Maurel attributed the former immunity of negroes to their vegetable diet, but since emancipation negroes had largely adopted the customs of the whites and consumed more animal food. A commission to study the method of inoculation was appointed, consisting of MM. Brown-Séquard, Cornil, Duval, Bourquelot, and Maurel.

ADULTERATION IN PARIS.

THE Paris Municipal Laboratory has recently done some good work, both from an economic and sanitary point of view. The adulteration of olive oil with American cotton oil has been practised to so large an extent that the public revenue and health are seriously affected. Olive oil is not only dearer in itself, but pays an entrance due of 16*s.* more per 100 kilogrammes than cotton oil. The result is that the falling off in the purchase of olive oil has considerably impoverished the French olive-tree cultivators. The public, however, consumes unknowingly the cheaper and less wholesome article. The olive stones are pulverised and mixed with pepper to an extent which causes an annual loss to the French treasury of £200,000, while bad coffee is dyed in Holland to give it a good appearance. Again, a tapioca called "tapioca indigéne" is sold and largely used as infant food, though it is made with potato, and is therefore not as nutritious nor as easily digested as the genuine article. Such are some of the grievances resulting from unscrupulous and unrestrained competition which the chemical laboratory established by the Paris Municipal Council has brought prominently forward. A special commission has been appointed to inquire into the matter, and hopes are entertained that active measures will be adopted.

VAGRANCY.

WE have repeatedly drawn attention to the very unsatisfactory rules and regulations in force with regard to the control of those numerous and ever-shifting items of our population known as vagrants. How numerous this class is may be shown by the fact that during the first eighteen weeks of the current year 2374 persons passed through the vagrant wards of the York Workhouse. This considerable population is always on the move, pushed on from the casual ward of one workhouse to the casual ward of another; often finding the greatest difficulty in obtaining a day's rest or the liberty of seeing the medical officer if ill. Mr. S. W. North, medical officer of health, in an interesting and valuable report recently read before the York Board of Guardians, speaks strongly on this point and of the obstacles that sick vagrants meet with in obtaining admission to any workhouse. Cases of acute ophthalmia needing early treatment often occurred, yet, never seen by the medical officer, they were pushed on by the master and other officials as only suffering from "a little cold"; cases are mentioned of severe ulceration of the legs, inflamed and sometimes gangrenous; chronic bronchitis and asthma, from which the persons must have suffered considerable distress; whilst instances of persons simply worn out by exposure, long travel, and want of sufficient food are common enough—all manifestly requiring medical relief, and all, unless the case seemed likely to prove immediately fatal, or the disease was manifestly infectious, sent tramping the next morning. Some boards seem more humane than others; but when this is the case, they suffer the usual penalty by attracting from all quarters the halt, the maimed, the sick, and the blind who have been ruthlessly rejected by their neighbours. To do away with the present scandal, Mr. North proposes that the Local Government Board should at once furnish the various workhouse boards and their officers with information with respect to the treatment of vagrants, and state plainly whether, in accordance with the Act, it is or is not the duty of the master of the workhouse, &c., to allow any vagrant alleging he is sick to see the medical officer, and also whether the medical officer can direct the admission from the casual ward into the workhouse of all persons who, in his opinion, after examination, cannot travel without risking an aggravation of the disorder or danger to life. Mr. North is of opinion that the Act 30 and 31 Vict. does apply to these cases; but it is of importance that the interpretation of the Act should not be left in doubt. If the vagrant is to receive no medical assistance, the sooner he is told so the better; he will not then waste valuable time by seeking relief in that quarter, but will turn to private charity. If the vagrant, by 30 and 31 Vict., is really entitled to admission from the casual wards to the workhouse, when it can be shown that he cannot further travel without aggravating his disease or endangering his life, then many masters of workhouses have broken the law by compelling vagrants to push on when utterly unfit to do so. In justice to the ratepayers, moreover, uniformity should be enforced; it is hard on a town, whose board adopts a liberal interpretation of the Act, to pay for the shortcoming of neighbouring towns whose boards are less humane. Either the Act

Digitized by Google

allows relief to vagrants or it does not; if it does, then all should bear the burden equally; if it does not, then steps ought to be taken to enforce a uniform rule for the relief and maintenance of sick vagrants.

HONOURS TO THE DENTAL PROFESSION.

THE announcement that the Queen has been graciously pleased to confer the honour of knighthood on Mr. John Tomes will be received with great satisfaction, not only by the dental section but by all branches of the profession. Sir John Tomes, who comes of an old Gloucestershire family, was apprenticed to a general practitioner at Evesham, and afterwards entered as a student at King's College and Middlesex Hospitals, at the latter of which he was house-surgeon for two years, and by his energy and scientific attainments won the esteem and sincere friendship of Sir Thomas Watson, Messrs. Henry Arnott and Campbell De Morgan, a friendship which only terminated with their lives; and it was chiefly by the advice of Sir Thomas Watson that he turned his attention to dental surgery. For some years he devoted a considerable portion of his time to the compilation of numerous papers on Dental Surgery and Dental Comparative Anatomy, and in recognition of his original researches was elected a Fellow of the Royal Society in 1852. To Sir John Tomes is due the gratitude of the dental profession for having prevailed upon the Council of the Royal College of Surgeons to apply for a charter to enable them to grant a licence in Dental Surgery, and in this he was greatly assisted by his friends Arnott, Lawrence, and Green, who were then members of the Council. Sir John Tomes was one of the first examiners in connexion with the new licence, and also on the original staff of the Dental Hospital, London, which he largely helped to found. In 1862 he was presented with a testimonial, consisting of a silver tea and coffee service, by his brother practitioners, "in acknowledgment of the many valuable services he has rendered to his profession." Some ten years ago, after a severe illness, he began to relinquish practice, and ultimately gave up altogether, but only to work all the harder for the interests of his profession. He was one of the most powerful promoters of the Dentists Act, which he always looked upon as a natural sequel of the granting of a diploma by the College. In 1883 the honour of the Fellowship of the Royal College of Surgeons was conferred upon him at the same time as it was upon Professor Huxley.

TARTAR.

THE situations upon which deposits of tartar are found upon the teeth are, in order of frequency, the lingual aspect of the inferior incisors—that is, opposite the openings of the ducts of the submaxillary and sublingual glands, the buccal surfaces of the upper molars which face the orifices of Steno's duct, next the buccal surface of the lower molars, and sometimes the lingual surface of the molars of both jaws. The deposit is never found upon the lingual aspect of the upper incisors, which are not bathed with saliva, and, moreover, are constantly being swept by the tongue. It is capable of being formed in great abundance, especially when from any cause, such as a carious tooth, one side of the mouth only is used for mastication. Tartar is composed chiefly of earthy phosphates and carbonates, with which is mingled a certain proportion of organic matter, epithelial scales, fatty particles, filiform fungi, vibrios, and monas. The relative proportion of phosphates or carbonates varies very considerably in different analyses, and this is due to the material being taken from different parts of the mouth. Thus, if from the buccal surface of an upper molar, it will be richest in carbonates, like the parotid saliva; whereas, when taken from the back of the lower incisors, it contains an excess of phosphates. Tartar is simply a deposition by precipitation of the salts held in solution in the saliva, which is brought about by its contact with air or mucus. The quantity of tartar varies largely in different subjects, for some salivas contain a small proportion of salts, and therefore the deposit is small; also if the precipitate meets with an acid—such as is so frequently found round the necks of the teeth and due to fermentation—sufficient to neutralise it, it will be redissolved. Thus the presence or absence of tartar has a clinical significance. If it is very abundant, it indicates an alkaline reaction both of the saliva and of the parts around the teeth, and a consequent immunity from caries; but if allowed to accumulate, it produces gingivitis by simple traumatic irritation. In some very rare cases it is entirely absent, owing to an acid reaction in the mouth, which leads to the most disastrous ravages upon the teeth. Between these two extremes there is every mean. The gingivitis due to tartar varies according to the quantity deposited; in a mild case there will be merely a line of redness along the free border of the gum; in a more severe case the roots of the teeth will be stripped of gum and its place taken by tartar; the gum will be festooned, have a fungating appearance, and bleed at the slightest touch; the teeth will loosen and change their position, owing to the inflammation having extended to the alveolo-dental membrane and the absorption of the alveolus. The treatment consists essentially in a vigorous use of the tooth-brush and the periodical removal of the incrustation. Any tooth-powder or preparation which will remove it must be acid, and therefore very deleterious to the teeth themselves. Mr. Bland Sutton has found accumulations of tartar upon the teeth of monkeys, kangaroos, and lemurs at the Gardens of the Zoological Society, where it is an occasional cause of death from septic pneumonia. These deposits are almost invariably found in association with a carious tooth or necrosed bone.

THE HYDROPHOBIA COMMISSION.

THE Commission are prosecuting their inquiries respecting the success of M. Pasteur's method. We understand that clinical reports of all the cases as they occur are supplied to the Commissioners from Paris. Whatever may be their verdict on the value of M. Pasteur's preventive treatment in the case of patients who have been bitten by presumably rabid dogs, there can be no doubt that our best and most reliable precautions against hydrophobia lie in the police regulations at present adopted in the metropolis. These regulations should be put in force throughout the kingdom. If this were done, and, as suggested by a sporting contemporary, a tax treble the ordinary amount imposed (and rigorously enforced) on female dogs, there would probably be no need for the employment of M. Pasteur's method in this country. We believe that of those bitten by reputed mad dogs only from 5 to 15 per cent. are subsequently attacked with hydrophobia.

REMARKABLE LONGEVITY.

A CORRESPONDENT of a contemporary states that he has just conducted an insurance upon the life of a man aged 102 years. This centenarian enjoys good health and appears to be in the possession of his faculties. He states that his father lived to the age of 110, and met his death from an injury due to the breaking of a mill-stone. His grandfather was, he asserts, accidentally killed in his mill at the age of 126. His great-grandfather lived to the age of 133. The man in question distinctly remembers his great-grandfather, and has now living a great-great-niece, so that he has seen seven generations of his family. It would be very interesting to have these facts thoroughly investigated, and if possible established.

OUR DIPLOMAS AND THE MEDICAL COUNCIL.

THE diplomas of the Royal Colleges of England are still in far greater demand than those of any other bodies in the kingdom. The latest table on this question contained in the Agenda of the Medical Council is interesting, especially at present, when there seems so much jealousy between rival bodies. The number of men passed by the Royal College of Surgeons of England is more than double that passed by any other medical authority in the kingdom. The Royal College of Physicians of London in this respect comes next. The College of Surgeons passed last year in the Final Membership Examination 561 candidates; the College of Physicians in the Final Examination for the licence 242, a number exceeding that of the Apothecaries' Society by 7. The great rival of the English Colleges, the Edinburgh University, confers its degree on little more than one-third of the number—viz., 196; Aberdeen University on 68; Glasgow University on 115. The Royal Colleges of Physicians and Surgeons of Edinburgh passed 91 gentlemen at its Final Examination. The King and Queen's College of Physicians gave its licence to 142. The University of Dublin bestowed its degree on 24. The Royal University of Ireland gave its M.B. to 76, and its M.C. to 58. The University of Cambridge passed in its Final Examination 26. The numbers passed in all the Final Examinations of the kingdom were—in the Division of England 1266, with 806 rejections; in that of Scotland 655, with 335 rejections; in that of Ireland 539, with 222 rejections. These tables are worthy of more attention than they generally receive from the Medical Council.

INSANITY AND CRIME.

THAT the criminal in general and the confirmed criminal in particular is mentally unsound may be as hazardous a doctrine as jurists are apt to call it, but it is one of which the French alienists have been most strenuous vindicators—in proportion, too, as their practice has favoured their cognisance of crime. Of these the ablest was certainly Dr. Legrand du Saulle, whose death we noticed on the 15th. He was already an accomplished physician, especially in mental disease, when he became Médecin en chef du Depôt—that parade-ground, so to speak, on which every morning the criminals of Paris are passed in review. Knowing exactly with what offence they were charged, and familiar enough with the law to appreciate the magistrate's view of their several cases, he never hesitated to apply to them the sifting process of which only the alienist is master. Hysteria in its protean forms, hallucination, mania in all its phases—he knew them not only in their mental and physical signs but in their characteristic acts; and the wretched creature whom a rough-and-ready police system would have relegated to prison with all its contaminating horrors, he would see occasion to put *en observation*, with the result of showing that the offence with which he was charged was as non-voluntary as if done in a dream, and that with the removal of the deranging cause a worthy life might be restored to itself and to society. As one by one the arrested of the previous night were brought before him, his keen scrutiny, aided by a centripetal question, would separate the calculating criminal from the unconscious one, and he would consign them to their several destinations accordingly. "What took you to the Place Vendôme, barefooted and bareheaded?" he would ask of a scared-looking female with the makings in her of a Madge Wildfire. "It is a case of *mania errabunda*," he would remark *sotto voce* to a professional bystander, and the poor night-walker is saved from the prison and is put *en observation*"—to thank, four years after, Dr. Legrand du Saulle himself, who recognises in her an honest *bourgeoise*, married and mother of a family. His experience was rich in such surprises, as indeed is not to be marvelled at when the average number of so-called criminal cases that passed under his scrutiny was 2500 a year. During the terrible weeks of the Commune, when every wayward impulse which a disorganised society could prompt enjoyed congenial opportunity, his work was aggravated and multiplied to an extent that put his resources of mind and body to the severest trial; but he survived it all, to earn the gratitude of many a saved life and of many a career unmarred. He wrote much, but, though far from averse to the refinements of classification, which seem so unreal to the "plain-man view," he was very careful to lay down no rules for the guidance of other physicians in circumstances similar to his own. Indeed, it is doubtful whether he could have succeeded in such a task if he had tried, for his power of diagnosis was as distinctly a gift as that of the born poet or the artist. He lived and worked, however, to secure this advantage for his profession—a far more respectful hearing in courts of law than had previously been accorded to the "medical witness."

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

WE may remind our readers that the election of new members to serve on the Council of the College will take place on Thursday, July 1st. The nomination papers, however, must be sent in to the Secretary at the College, duly filled in, not later than Monday next, June 7th. There will be four vacancies; three by lapse of time, and one in consequence of the death of Mr. Cooper Forster. Of the retiring Councillors, one (Mr. Allingham) we believe will not offer himself for re-election. The other two, Mr. Lund and Mr. Berkeley Hill, have signified their intention of seeking re-election. Under these circumstances, there will be two absolute vacancies. It is much to be wished that candidates will be selected, not on account of mere seniority or professional success, but rather on account of their special knowledge of College matters and their fitness to grapple with the political problems that have been agitating the Council for some years past.

MYSTERIOUS DEATH AT HACKNEY.

THE adjourned inquiry into the cause of death of Katherine Martha Huntley, aged twenty, was held at the Mermaid public-house, Mare-street, Hackney, on May 27th. From the evidence given on a former occasion it appears that deceased, a single woman, was living up to the time of her death as the wife of her employer under the name of "Mrs. Taylor," that she was five or six months advanced in pregnancy, and that, apart from the result of the post-mortem examination, there was nothing to throw any light on the cause of death. The symptoms were said to be "not inconsistent with the presence of an irritant poison." Dr. Tidy was commissioned to analyse the stomach and its contents. This gentleman obtained an alcoholic extract of a yellowish colour, which coincided, as did also the solid material found in the stomach, with the extracts from Keating's vermin powder. Dr. Tidy was of opinion that a quantity of this powder had been taken shortly before death. Experiments made on some rabbits gave negative results; in fact, one rabbit took as much as three ounces. It was found impossible to get dogs to take the powder. Our standard text-books on forensic medicine do not state what is the destructive element in Keating's vermin powder, but it can scarcely be a very potent one when a rabbit can take three ounces with impunity. We do not for one moment question the accuracy of Dr. Tidy's analysis and observations, but, to say the least, we think the inference that deceased had taken the powder was scarcely warranted by the facts stated in the report of the inquest, seeing that the active principle of the powder had

Digitized by Google

such few physical, chemical, and physiological properties by which it could be recognised. The stomach of deceased showed "signs of inflammation not uniformly spread over it, but in dark lines and patches." These signs, however, were far from showing that an irritant poison had been taken, since they may be produced by natural causes, such as typhoid fever, severe vomiting, &c. The coroner, in his summing-up, remarked, "such a heart as deceased had might bring about death at any time." Wisely as we think, the jury returned an open verdict without comment. In the newspaper report of the inquest we see no mention of the condition of the urine. This is important, for, in the absence of proof to the contrary, it seems by no means improbable that deceased may have succumbed to the effects of the albuminuria of pregnancy or of acetonæmia. The case as it stands remains as the jury left it—an open question.

CHOLERA INTELLIGENCE.

As we anticipated last week, the cessation of the daily bulletin of cholera cases and deaths in Italy by no means implied that the disease had ceased. It probably meant nothing more than that the Italian Government were anxious to avoid the imposition of measures of quarantine upon their vessels by foreign countries, and the silence was maintained only so long as the news did not find its way out by other channels. But on May 26th news came *viâ* Austria to the effect that at Udine on the Austrian frontier, and at the junction of two lines of railway to Venice, two deaths from cholera had taken place on the previous day. This was by no means the first proof which had been obtained, by an extension of the disease inland, that cholera was still prevalent at Venice. Following on this announcement, news as to cholera in that city has been resumed through Italian sources, and intelligence received from Rome to the effect that between May 27th and June 1st fatal attacks varying from twelve to twenty-one in number have occurred day by day, the whole number between those dates amounting to eighty-nine. There is still a cessation of news as regards the province of Brindisi and the town of Bari, where cholera was admitted to have held its ground up to the middle of the last month. Viewing all the circumstances, it is impossible not to regard the advent of July weather with grave misgivings in so far as European cholera is concerned.

GUARDIANS AND MEDICAL OFFICERS.

ONE of the chief wants in London is public opinion. The proceedings of local authorities are reported in the briefest way in local journals, which do not as a rule circulate outside the sphere of those who administer local affairs; hence nothing is often heard of their doings until some act of injustice is perpetrated and the public have been deprived of the services of a useful officer. The parish of St. Pancras has always been exceptionally unfortunate in this respect, and recent events have shown the need for greater watchfulness over its treatment of its medical officers. The independent performance of duty is not understood by the body constituting the chief local authority, and as a result, on more than one occasion, the officer has declined to submit to the intolerable persecution to which he is subjected, and has resigned his appointment. The board of guardians of the poor is, however, in some degree differently constituted; but, nevertheless, they appear unable to divest themselves of the tradition of the parish for which it has earned an unfortunate notoriety; for even those upon the board from whom, from their social position, other conduct might be expected, appear unable to refrain from adopting a method of annoying an exceptionally able officer. We read in a local newspaper which we have received that the St. Pancras guardians have adopted a recommendation of their Schools Visiting Committee calling upon Mr. Adams Clarke, the medical officer of their Leavesden schools, "to remove every case of infectious or contagious disease found in either of the quarantine houses to one of the infirmaries immediately such case is detected; and also that the medical officer be urged to be most careful not to discharge cases of contagious disease from the infirmary before being cured." The resolution, standing as it does without any expression of opinion that this officer has failed to observe so obvious and ordinary a duty, is calculated to make the guardians appear ridiculous, and Mr. Adams Clarke, who has taken much pains to promote school hygiene, and who, as a member of the Council of the Society of Medical Officers of Schools, is deservedly known as an earnest worker in the field of school health, can well afford to pass by silently this sterile record. But the treatment of medical officers in St. Pancras has come to be matter of serious public concern, and especial interest will be felt in this subject for the reason that a perusal of the local newspaper leads to the conclusion that two members of Mr. Clarke's own profession have agreed with the guardians in adopting a resolution which could have been only justified had there been a failure in duty on the part of that gentleman.

ENCOURAGEMENT OF PHARMACEUTICAL RESEARCH.

MR. THOMAS CHRISTY, in a paper on "New Commercial Plants and Drugs," laments the fact that Germany and the United States are so much more advanced and active in pharmaceutical investigation than we are, and appeals to scientific men amongst us, and especially to the authorities in our new technical schools in South Kensington and elsewhere, to give their help in the removal of this reproach. With our colonial empire the material is practically boundless, and it is nothing less than disgraceful that we should have to forward a plant sent newly to England to Germany to have its uses and properties ascertained. We would appeal to the Medical Council, with its accumulating funds and its great influence and responsibility as the source of the British Pharmacopœia, to aid in this matter. There is a commercial side, too, to this question, of great importance to England in these times, when new industries are wanted.

KING'S COLLEGE HOSPITAL.

THE festival dinner of this hospital was held in the hall of the Benchers of Lincoln's-inn on June 1st, under the presidency of Lord Halsbury, and the donations at the dinner and from the special appeal amounted to nearly £3400. One of the most interesting features at the dinner was the speech of His Eminence Cardinal Manning, who, in referring to the great increase of hospitals in London during this century on the voluntary system, remarked on the kindness which his poor co-religionists always met with, not only in King's College Hospital, but in all the large London hospitals. Surely no better testimony could be obtained with regard to the absence of sectarianism in these institutions.

AMERICAN PUBLIC HEALTH ASSOCIATION.

IN our last issue Dr. Saunders, one of the secretaries of the Society of Medical Officers of Health, called the attention of our readers to a meeting of the American Public Health Association, which will be held at Toronto in the early part of October of the present year. The Executive Committee have arranged an attractive programme, embracing the disposal of refuse matters, water-supply, school hygiene, epidemic disease, and the planning of dwelling-houses. There is no doubt the meeting will be

Digitized by Google

largely attended by medical practitioners on the American Continent, and the facilities which are offered to their European brethren for visiting Canada at very small cost should tempt those among us who are interested in public health questions, to exchange views with those who have considered hygienic problems under conditions different from those of England, and to enjoy the pleasant holiday which is promised them. The arrangements have evidently been made in the most generous spirit, and English practitioners will do well not to lose so good an opportunity of making themselves acquainted with the far West. Those members of the profession in England who have been so fortunate as to become familiar with the admirable work of their American *confrères* will be glad to learn that the names of Dr. John S. Billings and Dr. Ezra M. Hunt appear on the Executive Committee of the Association.

BELFAST MEDICAL SCHOOL.

ON the 26th ult. an enthusiastic meeting of the students of the Belfast Medical School was held in one of the lecture rooms of the Queen's College to hear a report from a deputation which, as stated in our last issue, had laid their grievances before the Senate of the Royal University of Ireland on the 25th ult. Dr. O'Neill reported the courtesy and kindness with which the deputation had been received by the officials of the Senate, and an association of medical students was formed, the objects of which were stated to be the careful consideration and remedy at the College, hospital, and university examinations of every just grievance of the members. The reply of the Senate to the claim for further representation of Belfast graduates as examiners is awaited with interest. It is to be hoped that the Senate will impartially inquire into the matters complained of, and, whilst refusing to be intimidated, will, in a just spirit, consider and remedy any abuses which exist in their system of medical examination.

SEWER GAS IN PARLIAMENT.

IT is a grim satire on the fatuity of the policy which finds favour in high places that the British houses of parliament should be condemned, as they now are, for their insanitary condition owing to defective drainage. It is abundantly evident that nothing short of a complete reconstruction of the drainage system will be effective. We would urge that the question of drainage and ventilation for the Palace at Westminster should be considered together and *de novo*. It will be less costly and incomparably better on all accounts to make a thorough change at once. The whole existing arrangement is bad and has been so for years. The committee-rooms and offices are, many of them, in a deplorable condition, and as yet the truth is very imperfectly known, and still less well understood.

"AN ERRING FELLOW."

AT the last meeting of the Faculty of Physicians and Surgeons of Glasgow, the conduct of a Fellow, in allowing his name to be attached to a much-advertised liniment, was seriously impeached. At the meeting referred to the Fellows were inclined to be lenient to their erring brother, and remitted the affair to the Council. The matter has now assumed a much graver aspect, and we are informed that the Council on June 7th will bring forward a report emphatically condemning his conduct from a professional point of view. A strong adverse feeling exists, yet we believe even at the eleventh hour justice would lean to mercy's side if the Fellow would acknowledge his mistake, and free himself and his name from any interest in the liniment.

THE EDUCATION OF DEAF-MUTES.

WE observe with satisfaction that the work of educating deaf and dumb children is being systematically carried on by the London School Board. Sixty per cent. of the children who are thus afflicted are now under tuition, and every effort is being made to classify the remainder in convenient groups. Necessarily, the centres of instruction are not yet numerous, but their number is increasing, and care is taken to distribute them over the metropolitan area. Three new classes are mentioned in the report just issued, at Drury-lane, Deptford, and Islington respectively. To second the efforts of the Board officials, time and trouble on the part of parents would be well spent in the endeavour to secure the attendance of any deaf-mute among their children at the nearest centre for this special form of instruction. The method followed is the oral or German. The merit of this system, we may remind our readers, consists in its teaching the mute whose defect is primarily an aural one to use his tongue in speaking and ultimately to read and write intelligently. He thus grows up a man deficient in hearing only, and able to exchange ideas with his fellow-men. A movement of this kind can hardly be expected to extend itself very rapidly. The disease is just rare enough to interfere materially with that concentration of the cases in districts which is so desirable. It may be expected, however, that the process of development, once begun, will not fail to go on, both in London and the country at large.

HOSPITAL MISSION WEEK.

THE scheme of holding six meetings in six separate districts of the metropolis on the six days preceding Hospital Sunday is gradually taking shape, though the particulars are not yet sufficiently determined for publication. Some good advocates have been already retained, including Sir Andrew Clark, the Earl of Dartmouth, Sir William Mac Cormac, the Right Hon. W. H. Smith, Sir Algernon Borthwick, M.P., Lord Northbrook, Sir Henry Holland, the Duke of Westminster, K.G., Mr. Murdoch, M.P., the Duke of Cambridge, and Lord Salisbury. The political crisis should only enhance the interest of such a week by drawing men of all classes and creeds together for the high purposes of human help to the sick poor.

AUSCULTATION OF THE EYEBALL.

M. GENÉ has recently described to the Biological Society of Paris a new method of estimating the tension of the eyeball. This consists in auscultating the organ by means of M. d'Arsonval's telephone. The instrument is applied to the globe, and a sound, such as that of the interrupter of a faradisation instrument, made to pass: the differences of degree and intensity of the sound as perceived by the observer afford a valuable and accurate means of diagnosis. M. Gené's experiments being as yet somewhat incomplete, he hopes at some future time to lay the subject before the Society in greater detail.

A FIREMAN'S DUTY.

THE recent case in which the absence of a fire-escape man from his post is alleged to have been the cause of loss of life has attracted attention to the need of reform in respect to the "duty" of firemen generally. There can be no question that the Metropolitan Brigade is sadly undermanned; and to this we owe the fact that firemen are practically never "off duty," except when they have special leave of absence. This is a most regrettable state of matters, but the remedy is very simple: expend a little more money on the Brigade, and Captain Shaw will soon know how to secure and train a larger number of men.

Digitized by Google

MILITARY MEDICAL SERVICE IN SPAIN.

THE Spanish Government, having recently established a military medical academy, through which all military medical officers will as a rule have to pass, has just issued a long programme of regulations regarding the admission of candidates to this academy. It is open, of course, only to Spanish subjects, who must be licentiates or doctors of medicine of a Spanish university, under twenty-eight years of age, and of good character and physical constitution. The selection will be made by open competition, consisting of four examinations or exercises. The first takes the form of an extempore dissertation in writing, limited to four hours, on a subject connected with pathology, therapeutics, hygiene, or forensic medicine, drawn by lot out of an urn; the second exercise is entirely clinical, and consists in the examination of a patient, also drawn by lot by the candidates. The third is *vivâ voce*, and the fourth an operation on the dead body.

LEICESTER PROTECTED BY VACCINATION.

ONE of our Commissioners has been to Leicester to ascertain for himself if that town is really so independent of vaccination for its immunity from small-pox as some might think from what they read of the neglect of the vaccination laws by the sanitary authorities. All who are interested in vaccination, either in its scientific or sanitary aspects, will do well to read what he says. He does full justice to the sanitary arrangements of Leicester. But he shows that the first line of defence again the horrible disease there, as everywhere else, is vaccination and revaccination. The medical officer of health is revaccinated; so are the sanitary inspectors; so are the nurses of the Infectious Hospital. Without such use of the beneficent operation so much decried by the Leicester authorities all their officers would be disabled, and all their boasted arrangements mocked. After this it may be hoped that these authorities will speak a little more gratefully of vaccination.

A MISSION TO THIBET.

A MISSION is shortly to be despatched to Thibet for the purpose of establishing friendly commercial relations between that country and India. The mission leaves Bengal for Lhasa, the capital of Thibet, about the end of May or the beginning of June, and Mr. Colman Macaulay will go as political officer in charge. Dr. A. Leahy, of the Indian Army, will also accompany it as medical officer. This expedition should be fraught with the greatest interest, as the country to which it goes is almost unknown. In 1811 a gentleman named Manning, after learning to speak Chinese in Canton, visited Lhasa disguised as a Chinaman, but neither before nor since that time has any Englishman ever set foot within the walls of the holy city of the Dalai Lama.

OPHTHALMIC OPERATIONS AND TETANUS.

DR. D. JUAN SANTOS FERNANDOS, of Havana, gives in the *Crónica Médico-Quirúrgica* an account of a fatal case of tetanus following the extirpation of the eyeball for atrophy following the removal of a sarcomatous tumour from the orbit. In commenting upon it, he remarks that the only four other cases of tetanus following ophthalmic operations which he has been able to find in medical literature all proved fatal, which tends to show that though tetanus rarely follows such operations, it is particularly dangerous when it does supervene. In none of the cases was the operation intraocular merely, such as cataract extraction or iridectomy, a class of operation which Dr. Fernandos believes never to have been followed by tetanus.

CLUBS FOR YOUNG WORKWOMEN.

IN accordance with the universal conviction that work, if it is to be hearty, effective, healthy, and successful, as it should be, must give place at times to recreation as well as rest, a movement exists for the establishment of clubs for young workwomen. The promoters of the scheme appear to appreciate very fairly the requirements of their case. They recognise the fact that idleness is not profitable, as a rule, even in leisure time; that diversion of energy, mental and physical, albeit a light diversion, is an essential part of recreation, and that such diversion must vary in particulars to suit varieties of temperament and habit. Books, magazines, music, round games, have all their advantages, and these come naturally to form a part of the plan. In order to be of real benefit, they must, as Mrs. Fawcett aptly observes, be of the best. We may be allowed, as taking a professional interest in the subject, to suggest that space should be a prominent object in the selection of rooms for this purpose, and that ventilation by the outer air be insisted on. Bright fires and brilliant gas are useful adjuncts to such an establishment. At the same time they must not be over-done, so as to impoverish the atmosphere. It is also worth remembering that a club does not necessarily lose its utility in summer, though the time at which in-door occupations are most suitable may be somewhat postponed. The effect of personal influence is an important factor in the success of such institutions. In no case need the fruit of good intentions and efforts be at once expected, but there is very little doubt that if some energy and tact be devoted to the work, or, as we may say, invested in it, the result will repay the trouble taken.

A CONVENT TURNED INTO A HOSPITAL.

A CHARITABLY disposed Mexican lady having left a large sum of money for the purpose of building a hospital, her executors have obtained an old convent in Regina and fitted it out magnificently, according to their lights, for the reception of patients. Though there is plenty of luxurious display, the arrangement of the wards is, as might be expected, far from conducive to isolation or good ventilation. For this no provision has been made, the air having to enter and pass out as best it can. The drainage, too, is very unsatisfactory. Altogether it is a great pity, according to *La Voz de Hippocrates*, that a building of less pretentious appearance, but of better hygienic construction, was not erected with the deceased lady's wealth.

CLUB-FOOT.

PROFESSOR VERNEUIL lately cured a severe case of club-foot by removing the scaphoid, cuboid, astragalus, and a part of the os calcis; the vast gap notwithstanding, the child recovered perfectly and was able to walk very fairly. An open dressing with iodoform was employed.

FOREIGN APPOINTMENTS.

THE University of Havana has elected Professor Dr. D. José Maria Carbonell y Ruiz as Senator. M. Jourdan has been appointed Professor of Histology in Marseilles. Dr. Stintzing of Munich has been appointed Extraordinary Professor of Children's Diseases in Berlin.

CARPET-BEATING IN SUBURBAN GARDENS.

THE beating of carpets in suburban gardens, and, we may add, in the back-yards and courts of houses generally, is a great nuisance. The noise is irritating to invalids especially, and to the multitude of sensitive folk

Digitized by Google

Moreover, it is not a sanitary process by any means, this accummulation of dirt in carpets, with periodical disseminations of the disgusting and perhaps noxious filth in the atmosphere. It would be wiser far to adopt measures for cleansing carpets in properly heated chambers than to scatter the dust they contain broadcast.

DR. D. NICOLSON has been appointed by the Home Secretary Medical Superintendent of Broadmoor State Lunatic Asylum, *vice* Dr. Orange, resigned. Dr. Nicolson has seen nearly twenty years' service under the Home Office, having been assistant-surgeon at Portland, Woking, and Millbank Prisons. He was transferred in 1876 from being senior medical officer of Portsmouth Prison to be Deputy Superintendent at Broadmoor.

A PAPER will be read by Dr. Thorne Thorne at the next meeting of the Epidemiological Society, at 8 P.M. on Wednesday, June 9th, on the Results of the International Sanitary Conference of Rome. The Society meet in the rooms of the Medical Society, Chandos-street.

THE death is announced of Dr. D. Francisco Ortega, Director of the Medical School of Mexico.

Pharmacology and Therapeutics.

SAVORY AND MOORE'S MEAT PEPTONE AND PEPTONISING PELLETS.

THE objection commonly made to all preparations of meat peptones is that they have a nauseous sickly taste. The difficulty has at last been overcome by Messrs. Savory and Moore, who have recently introduced a meat peptone which fulfils all the requirements of the sick-room. A small jar containing one ounce, when mixed with hot water, makes, without further addition or seasoning, a pint and a half of palatable and appetising soup. The peptonising pellets issued by the same firm are excellent, and will be found useful for predigesting milk.

MARTINDALE'S COCAINE PASTILS AND TABLETS.

Cocaine is of such value as a therapeutic agent, and is now so commonly employed in the treatment of a variety of different complaints, that pharmacists are naturally desirous of presenting it in as agreeable a form as possible for administration. Mr. Martindale sends us specimens of cocaine pastils, presumably made with a basis of glycerine and gelatine. They are attractive in appearance, and have little or no taste. They are recommended "for giving tone and flexibility to the vocal organs, and allaying irritation of the throat, trachea, and vocal cords." They are said also to be useful "for irritated conditions of the stomach, nervous depression, and distaste for food from various causes," and it is added that they are "specially adapted to the wants of singers and public speakers." They presumably contain one-twentieth of a grain in each, although, curiously enough, the strength is not stated on the label. Respecting the value of cocaine as a remedy for sea-sickness, there is still much difference of opinion; but Martindale's cocaine tablets undoubtedly form one of the most convenient methods of administering this remedy. Prescribers are indebted to Mr. Martindale for the energy he has displayed in preparing these pastils and tablets.

STATIC ELECTRICITY IN TABES DORSALIS.

Static electricity has been made use of in tabes dorsalis by Dr. Shurigin, who discusses the subject in the *Vrach*, and concludes that this form of treatment is beneficial if it is commenced before any visible atrophic and paralytic ymptoms have made their appearance.

BENZOYL-ECGONINE.

The physiological action of benzoyl-ecgonine has been studied by Mr. Ralph Stockman, who has communicated his results to the *Pharmaceutical Journal* of April 24th. The subcutaneous injection of from one-tenth to one-third of a grain caused slowly developed muscular stiffness, and the pupil gradually dilated. In from eighteen to twenty-four hours after the administration the reflex actions became greatly exaggerated, this increasing until the slightest irritation brought on tetanic spasms. This condition may last one or more days, and the frog ultimately recovers or dies of exhaustion. Division of the spinal cord at the medulla had no effect in hindering the appearance of convulsions after these had become established. With moderate doses the rapidity of the heart's action was increased; large doses caused great irregularity and arrest in diastole. No effect was observed on the vessels of the web. The sensory and motor nerves were unaffected. On striped muscle it acted as a poison like caffeine. A rabbit received twenty-four grains subcutaneously without apparent effect. Cats were more susceptible; twenty-four grains subcutaneously injected caused diarrhœa and vomiting, with dilated pupils, tetanic spasms, and death. The heart was in a relaxed condition, but the intestines were firmly contracted. Benzoyl-ecgonine appears, therefore, to be practically identical in its physiological action with caffeine, although there are some minor points of difference. The chief action of cocaine—paralysis of the sensory nerves—is absent; in fact, the relationship between the action of the two substances seems to be as profoundly altered by the subtraction of the methyl group (CH_3) as obtains in the analogous case of methyl-strychnine and strychnia.

IODOFORM AND NITRATE OF SILVER IN INDOLENT ULCERS.

Dr. Maethe, writing in the *Norwegian Medical Archives*, recommends a combined application of iodoform and nitrate of silver to indolent ulcers, fistulæ, and all badly healing granulating surfaces. He first applies a thin coating of powdered iodoform, and then cauterises with nitrate of silver, after which more iodoform is applied. There are formed in this way nitric acid, iodoform, and iodide of silver, and their nascent condition effects a great change in the conditions of tissue life. The advantages of this method of treating ulcers are that the action is purely local and that the cicatrisation of the surface is effected under an antiseptic covering.

OSMATE OF POTASSIUM.

Merck of Darmstadt has prepared the osmate of potassium to obviate the use of osmic acid, which is so irritating to the respiratory organs, and so hygroscopic. The *British and Colonial Druggist* is informed that an English firm has also manufactured the sodium and lithium salts. The potassium compound is said by Wildermuth to have proved beneficial in some cases of epilepsy, the daily dose being one dozen pills, each containing $\frac{1}{24}$th of a grain in combination or alternation with bromide of potassium. A 1 per cent. solution of the potassic osmate has also been recommended in the treatment of goitre, neuralgia, tumours, and other diseases.

PHARMACOPŒIAL OPIUM.

In an article published in the *Chemist and Druggist*, Mr. John Moss points out the variable quality of different opiums, that which contains 8 per cent. of morphine being sanctioned in the Pharmacopœia. It is also shown that Turkish opium, as well as the best grown in Smyrna and Asia Minor, generally yields from 12 to 15 per cent. Mr. Moss suggests that the morphine standard of opium should be raised from 13 to 15 per cent. in powdered opium, to encourage the production of high-class opium in Asia Minor, and permit the use of Turkey opium, which is not merely rich in morphine, but uniform in richness.

CHIONANTHUS VIRGINICA.

The root bark of the "snowdrop tree" or "fringe tree" of North America, an oleaceous shrub or small tree, has been found by Dr. Henning to be a useful aperient, cholagogue, diuretic, and alterative. A liquid extract is prepared and given in doses of one fluid drachm thrice or twice a day. In jaundice its value is said to be conspicuous; it is not a powerful hepatic stimulant, but it is of value in portal congestion.

GUY'S BIENNIAL DINNER will be held on July 2nd, not June 2nd, as stated in our last.

MEDICAL DEGREES FOR LONDON STUDENTS.

A SPECIAL general meeting of the Metropolitan Counties Branch of the British Medical Association was held at the Royal School of Mines on the 31st ult., Dr. Walter Dickson, President of the Branch, in the chair. The attendance was fairly numerous.

The CHAIRMAN, in opening the proceedings, recapitulated the steps taken by the Branch since its meeting on March 6th, 1885, to carry out the resolutions then passed. He said that upon the question of giving facilities to London students for medical degrees depended the future welfare and prosperity of London as a school of medicine; and he reminded the meeting that the question was raised in the Branch in 1879, in which year also Dr. Bristowe addressed a letter to the Chancellor of the University of London upon the need for reducing the stringency of the Matriculation and Preliminary Scientific Examinations. He referred to the origin of the Medical Faculty of the Edinburgh University by the united efforts of the Colleges of Physicians and Surgeons of that city to furnish the first professors, and spoke of the great impetus given to that faculty when Monro primus was appointed Professor of Anatomy in 1720. He also pointed out that as long ago as 1827 the proportion of English students graduating in the Medical Faculty of the University of Edinburgh was greater even than at present. But the unrivalled clinical opportunities of London demanded that it should take a foremost place in medical education.

Sir ANDREW CLARK, on rising to move the resolution, said that the question was a very grave one, that it was about to be taken up by the greatest Medical Association in the world, and that it would not, therefore, in the end fail to be carried. In the statistical report compiled by Dr. Gilbart Smith, and in Dr. Hickman's pamphlet, the subject was viewed so exhaustively as to leave little to be said. It is a fact that the number of medical students in London is steadily decreasing, whereas in other parts of the country they are increasing. Why do they leave London for Edinburgh? Is it because the teaching is better or living cheaper? No, everything leads to this result: that after their education they are examined by their teachers, and in the end get a degree which is far more profitable than a licence to practise. This is the grievance, and it is a just one. The curriculum is equal, the examination is equal, the age is equal; but the result is an unequal symbol of efficiency. In some senses it is a sentimental grievance, but not merely so, for it is also a real practical grievance, which affects medical men in England not only socially and materially, but even in their practice with their professional brethren, for the holder of a degree is held in higher estimation than the holder of the diplomas of the two Colleges. The grievance is widely and seriously felt, and to such an extent that parents and guardians send their children elsewhere than to London for their education. As there is no reason to believe that education in London is below that of Scotland, they had a right to claim that those who are trained here should obtain the symbol which should testify as much as if they had been educated in Glasgow or Edinburgh. It must not be forgotten that medicine is an art, and must be learned by observation and work in the hospital ward. There is no medical school in the world where there is such practical teaching and so much personal influence of the teacher upon the pupil as in London. There is no need to disparage Edinburgh; its success has rendered this impossible; there are at least 2000 medical students there, and how is it possible to teach them otherwise than by lectures? And how can any didactic teaching, however good, make a man a doctor? The University of London has done an enormous work in raising medical education and giving a dignity to medical degrees which they never had before; but it has committed one grave mistake in insisting upon a knowledge of moral philosophy at the M.D. examination and rejecting in this subject some of those who were best in medicine. He characterised this introduction of so vast a subject at the close of a medical curriculum as a sham and as offering a premium upon "cramming." They could not go to the University of London to remedy this grievance, but there was a prospect that the two Colleges of Physicians and Surgeons might unite and form a Teaching University, and thereby do a great service to society and the State. If rightly constituted (with the introduction of an examination in preliminary science and of a third practical examination at the close, a university would be formed which would not only be venerable in age and catholic in its constitution, but which would be able to give strength to the profession and fulfil better the work which is demanded of the Colleges. He had been struck with the paucity of the objections to this scheme. It had been said, what is the good of founding a new university when there is already one in London? But why, he asked in reply, is Scotland, with its 3,000,000 or 4,000,000, to have four universities, and London, with its 5,000,000, to have only one? Again, it was objected that students would be deprived of culture and refinement. But culture is innate; it is that in a man which enables him to see, beneath the common things with which he deals, all that is pure, just, true, and good. There is no need for a university to bring this out; and if he felt that the proposed scheme would deprive men of culture he would oppose it. Sir Andrew concluded by moving, "That negotiations with the University of London not having led to the desired result, this meeting recommends that the Royal College of Physicians of London and the Royal College of Surgeons of England be requested to endeavour to obtain power to grant degrees in Medicine."

Mr. JONATHAN HUTCHINSON seconded the resolution, and said that he had long ago advocated the union of the Colleges and the granting of one general title to all general practitioners. One of these objects had already been attained, and no one who took a broad view of the interests of the English profession could fail to support the other question. It was absurd that there should be such a difference in the matter of titles among men who are exactly equal as to their professional attainments; and the existence of these differences led to much heartburning and rivalry, as well as confusion in the public mind. If such common title were conferred, it had been said that it would be unjust to those who possess university degrees; but each degree-conferring body must stand on its own merits. Universities were originally local, and it is not consistent that men educated in London should be sent to graduate at John-o'-Groats because in mediæval times a university had been founded at John-o'-Groats. It was not at all unjust to existing universities to create a new one. The difficulty might be surmounted by asking, not for a degree but for a title, something which would not imply a "university education"; indeed, it is absurd that the Colleges should ask for powers to give a university degree upon a merely medical curriculum. But the title "Doctor of Medicine" was different from the degree M.D., and the conferring of such a title would work no injustice on the holders of degrees. If the title were granted to all who held the double qualification, there might be a little temporary injustice to those who had but one qualification; but, as a matter of fact, he had found that the senior practitioners were those who cared least for a change which was almost universally felt by the juniors as essential and necessary to success. The possession of a degree-granting monopoly by the universities had led to a degradation of the university curriculum; for in many of the most meritorious universities a man may at once proceed to professional studies with no further evidence of general education than the ability to pass his "little-go." The only restriction imposed by a university was that the student must go "into residence"; but this, instead of a good, becomes an evil when it takes a student from his clinical work in London just at the time when he will most profit by it. The examinations of the Colleges of Physicians and Surgeons are equal to those of the universities; many have the same examiners; and, since the number of examiners was greater in London, the risks of injustice to candidates were much lessened. He would not grant the title to all licentiates, but only to those who, a year after qualifying, should pass a purely practical examination, which need not be one whit stronger than the previous examination, whilst it would encourage men to keep at hospital work for another year.

Dr. PYE-SMITH, as a graduate of London University, thanked Sir A. Clark for his liberal mention of it, but asked whether it was correct to say that negotiations had failed with the University, which was at present engaged in considering questions of reform. It is important to distinguish between making an examination easier to pass and making it easier to take degrees. The examinations of the London University need not be diminished in severity, but it is quite possible to facilitate the taking of degrees—e.g., by making examinations more frequent, deviating from their

Digitized by Google

strict order and in other ways. So that it is not hopeless to render the degrees of the London University more accessible; but if any benefit is to be gained from the University the standard must not be lowered. He admitted the present grievance, but asked if from a certain date all students be admitted to the title of Doctor or the degree of M.D., would not great injustice be done to those who had taken their diplomas in the preceding years. If additions were made to the present College curriculum for intending graduates, the grievance would not be thoroughly remedied; and if, on the other hand, all London students were admitted it would make the degree equivalent to a minimum qualification. Again, if the London Colleges gained the power to grant degrees, the colleges in Edinburgh and elsewhere would obtain it also. For his own part, he felt that this university title, which is of no meaning, should be put an end to, and would be glad if the prefix "Dr." could be dropped by graduates. After all, the most important question is untouched by the resolution—he meant the status and education of London students. We are in want of university life in London. The prospect of founding a medical university is delusive; but it is possible for existing institutions to combine and form a real useful university, which should not simply exist to give degrees, but should widen and deepen the training of students and raise the tone of the profession.

Mr. MACNAMARA pointed out that it was not suggested that every student should be granted a degree, but that the anomaly should be rectified whereby in Scotland 86 per cent. of the medical students graduate, whereas in England only 12 per cent. do so. No one would dream of asking that powers should be granted to confer degrees upon minimum terms. The branch had sent two deputations to the University of London, but had had no response, and he would ask how much longer they were to wait for it. The scheme for founding a Teaching University did not touch this question. Our medical students find themselves practically shut out from degrees, or else they break off their career in London in order to go elsewhere to obtain them. He had not heard any reasonable objections to the right being given to the Colleges of Physicians and Surgeons; and if they could be got to unite for this purpose they might draw up a well-devised scheme to carry it into effect.

Dr. W. J. COLLINS pointed out that the University of London had already made reforms in the direction of the memorialists of last year. Two preliminary scientific examinations were now held annually; the scheme of Mr. Magnus, based on that of Lord Justice Fry, was in the direction of increasing the educational authorities in the Senate, and was now passing through Convocation; the subject of Moral Philosophy at the M.D. had been replaced by Mental Physiology. It seemed to him that the ideal sketched in the Report of the Branch Council last year was to reduce the London University to the plan of Edinburgh, in order to enable the majority of students to take medical degrees. The whole question was one of insufficient preliminary education, and he predicted that the natural tendency of this movement would be a downward one.

Dr. HABERSHON said that one would think, from the remarks of Drs. Pye-Smith and Collins, that it was contemplated to grant an insignificant degree, but this was not their object; on the contrary, it was hoped by this movement to raise the standard of education. The matriculation examination of the University of London embraced so many subjects and such difficult questions that it encouraged cram; for no matter how well a student succeeded in one subject, if he failed in one he was rejected in all. The Preliminary Scientific Examination also tended to make the London degree an exclusive one, and the changes made by the University did not meet this point. His late colleague, Dr. Mahomed, in order to obtain a degree which carried more weight with it than the one he already held, was obliged to travel to Cambridge every night in order to "keep terms," as if that would qualify him any the more for holding a degree for which he had a right. He did not think the examinations for the M.R.C.S. and L.R.C.P. were insignificant; they were equal to those of a University; and if a preliminary examination were introduced, not inferior to those of other Universities, their candidates might then justly demand a title not inferior to those obtained from a University. He fully endorsed what had been said of the value of clinical work in London, and would not urge anything which tended to lower the standard of professional education.

Dr. MOXON said that the arguments of Sir A. Clark had not been met. The fact was that the degrees of the University of London were too stiff to be obtained by the majority of students, and whatever changes might be made, there would never be anything done to lower the degree. He did not think Drs. Pye-Smith and Collins were in earnest in holding that if degrees are to be given on a large scale they must be given in the very lowest standard. He felt that in this vast metropolis, where many persons more or less distinguished practised and taught, they ought to have, not the smallest and most dwindling of medical courses, but the largest and most important. That lofty and honourable body, the University of London, must not refuse to allow others to do what it was unwilling or unable to effect.

Dr. WALTER SMITH, commenting upon the confusion that existed whether a title or a degree should be asked for from the Colleges, advocated the formation of a Teaching University, and moved an amendment to insert after the word "recommends," instead of the remainder of the resolution, the words, "that steps be taken to found a Teaching University for London."

Mr. SWINFORD EDWARDS seconded the amendment.

Dr. BROADBENT said that although the primary object was to request the two Colleges to give degrees in medicine and thus remove a serious grievance, yet beneath that there was the other object of raising the culture of London medical students. It would be one way of starting a Teaching University; and already the Colleges possessed a site upon which they could found a great scientific institution. From this movement all the advantages of a Teaching University would be obtained; but to suppose that the scheme now before the University of London would meet these wants was trifling with intelligence.

Dr. SANSOM said that at the last meeting of Convocation there was evidence, both on the part of Mr. Magnus and others, that no opposition to this movement would come from the existing University.

Sir A. CLARK, in reply, said that Dr. Collins had no shadow of ground for his assertion that one of the issues of this movement would be a competition downwards to a minimum degree. The Colleges had progressed upwards in raising the standard of their examinations, and there was no reason why they should go back. Drs. Pye-Smith and Collins would admit that the degree of the University of Edinburgh is an honourable one; and he contended that the examinations for the double qualification of the Colleges were precisely equivalent to those of Edinburgh University, one difference being that in Edinburgh students are examined by their own teachers. He satirised the substitution of Psychology for Moral Philosophy at the M.D. examination of the London University, and concluded by affirming that it was the object of the promoters of this movement to make Doctors of Medicine, and that their contention had not been gainsaid.

The amendment was then put and lost, only the mover and seconder voting for it.

The original resolution was then put and carried, with but one or two dissentients.

LUNATIC ASYLUMS, 1885.

No. II.

A VERY interesting report is sent in by the Superintendent of the Sussex County Asylum at Hayward's Heath (Dr. Williams). He finds that the forms of admission accompanying patients are often very imperfectly filled up, and that in some cases they have been absolutely invalid, necessitating the refusal of admission to the patient until the form was amended. "The imperfect filling up of these forms is a very serious matter: because, on the one hand, if the asylum authorities admit and detain an alleged lunatic on an imperfect order of admission, they may render themselves liable to an action for illegal imprisonment; whilst, on the other hand, the delay caused in taking a patient back to have the imperfect order amended may be of the greatest harm to him, besides causing endless worry to all concerned."

Dr. Campbell gives a sad tale of hopelessness for the inmates of his asylum (Garlands). "At the present time," he says, "there are only 16 males and 49 females out of the total number of 850 in the asylum in whom there is the slightest

Digitized by Google

prospect of recovery. All the rest are either idiots, imbeciles, dements, or chronic lunatics, whose mental aberration can only terminate with their death"—that is to say, a proportion of 1 in 13. With a view to the more systematic instruction of the attendants and nurses in their duties, Dr. Campbell has prepared a pamphlet for their guidance. Each attendant and nurse receives a copy of this pamphlet on their arrival. We regard this as being a step in the right direction, and would be glad if such a course were taken more frequently, for it too often happens that new attendants are left to learn their duties at haphazard. We have a copy of Dr. Campbell's little work before us; it is entitled "Hints for the Guidance of Attendants on the Insane," and we can thoroughly commend it as being likely to serve a most useful purpose.

At the Derbyshire County Asylum, the Superintendent (Dr. Murray Lindsay) says the high mortality (14·93 per cent. on the daily average number resident) is "again attributable to the excessive number of deaths from pulmonary consumption, and to the very unfavourable character of the cases admitted, many of whom were in such a debilitated or diseased condition that they died within short periods of admission, one man only surviving five hours, and another nine days, eighteen dying within twelve months of admission. Dr. Lindsay laments that the proposal to erect a detached hospital for the isolation and treatment of infectious disease, "a matter so urgently pressed by the Lunacy Commissioners," was negatived by his committee on the ground of expense. They, however, have granted him a solatium in the form of a disinfecting-room and apparatus costing £300. Dr. Lindsay records his thankfulness for this small mercy; but states that a disinfecting apparatus "is only one weapon, and that not the strongest, in the necessary armour with which to fight the battle of infectious disease."

The Surrey County Asylum at Cane-hill is as yet an asylum without a history, but it would appear to be starting under favourable auspices, for the Commissioners in Lunacy, in recording their first visit since its occupation by patients, are able to say that, "considering the short period which has elapsed since this asylum was opened, the progress made in its adaptation to the purposes for which it was built is highly creditable to the committee and medical superintendent." The death-rate is somewhat high. One patient, according to Mr. Moody's report, would appear to have put one of his delusional ideas to a practical test. "This man was the subject of general paralysis, with delusions of an exalted character, one of these being that he could fly. Suddenly, without any warning, he threw up a window, got his legs on the ledge, and slid off, falling to the ground a distance of eighteen feet." He survived the experiment for ten days.

"Herefordshire," says Dr. Chapman in his report as Superintendent of the Hereford County and City Lunatic Asylum, "has always had a larger proportion of lunatics to population than any other county; it now has just over 4 per 1000; the average for England and Wales is 2·59 per 1000." Dr. Chapman is afflicted with a plethora of "idiots and persons over seventy years of age," cases of helplessness, which he thinks should largely and more fittingly be provided for in workhouses. The chief result, apart from the mortality, that arises from the presence of these helpless and dirty patients is that the "foul washing" amounts to something considerable; and, curiously enough, the amount would appear to double itself every five years. And Dr. Chapman gives statistics which fully bear out his remark. It is perhaps not to be wondered at that erysipelas showed itself twice during the year. The death-rate, however, is "again very low—viz., 5·2 per cent. on the average number resident"; and Dr. Chapman thinks the abundant out-door exercise the patients enjoy must take a first place in explaining the low death-rate, added to which there are the abundant dietary and the warmth of the clothing; and doubtless these are all very essential points, and points not always sufficiently looked to in the treatment of patients in asylums.

The Superintendent (Dr. Spence) of the Staffordshire County Asylum at Burntwood refers to the total number of admissions for 1885 as being less than for any year since 1880. "A part of the decrease may, in all probability, be attributed to the not unnatural reluctance on the part of medical men to undertake the duty of certifying patients in face of the present state of the law, which appears to render them liable to considerable worry, to say nothing of pecuniary loss, no matter how conscientiously the duty of certification may have been performed." We are glad to see that Dr. Spence has "introduced a plan for the systematic weighing of every patient once a month." In our opinion this practice is a most useful one; it serves to bring to notice the falling off in weight of quiet uncomplaining patients, and it often checkmates the noisy clamour of grumblers who are "being starved," by showing an increase in their body-weight.

At the Barnwood House Hospital for the Insane, Dr. Needham reports that a considerable number of patients have again had to be refused from want of room, also that the admissions were marked, in the great majority of cases, by extreme despondency and a suicidal disposition, but that there is no casualty to record. On the question of "open doors" Dr. Needham thus expresses himself: "While personal freedom has been widely extended to the patients, I have still been unable to persuade myself of the practical value or expediency of the general application of an arrangement which has been called the 'open-door system,' and which I have therefore not attempted to adopt generally."

The Superintendent of the Asylum for the City and County of Bristol (Dr. Thompson) attributes his unusually high percentage of recoveries during the year as being to some extent due to the partial stoppage of the system of allowing new and acute cases to rest for a longer or shorter period at the workhouses. His remarks on the successful results of the introduction of Cornish boilers with the view of keeping the asylum "always in hot water" are well worth attention.

Dr. Glendinning, the Superintendent of the Joint Lunatic Asylum at Abergavenny, reports that, although the number of the admissions for the year was low, they were not of a very favourable character, as only 60 per cent. were deemed curable. Frequent changes took place among the attendants, but "dismissal for misconduct or ill-treatment of the patients has been seldom found necessary."

LEICESTER, AND ITS IMMUNITY FROM SMALL-POX.

(*From our Special Commissioner.*)

THE public hears so much about the neglect of vaccination in Leicester and the absence of small-pox that in a less enlightened age we might be in danger of a reversal of public intelligence on the subject. The protection of the community from a plague so deadly and so disgusting may well excite admiration, whatever arrangements conduce to so great an end. It is of great moment, therefore, to ascertain what the arrangements are. Jenner is a great name in medicine, and is not likely soon to lose its fame. And small-pox, when it occurs, can be as fatal at Leicester as anywhere else. It is sometimes hæmorrhagic, sometimes confluent. In 1877 of twelve cases five died. Isolation and disinfection, promptly and thoroughly carried out, are the vaunted measures in Leicester, and to read the newspapers, or even the sanitary reports, one would almost think they were all-sufficient. For ten years they have not had a great epidemic. Much inflammable material is being prepared. But does not Leicester by sanitation and isolation almost nullify the fact, and justify its authorities in their disrespectful and even hostile attitude to vaccination?

The methods of Leicester are thus summarised in the Annual Report for 1884 of the Sanitary Condition of the Borough, by the late able Medical Officer of Health, Dr. William Johnston:—

"During the last eight years there have been no fewer than twenty importations of small-pox into the town and its immediate neighbourhood; the *disease has always been stamped out, owing to the fact that the Health Committee have always succeeded in promptly removing to hospital, not only those stricken with the malady, but also all the other inmates of each infected house.*"

I make this quotation because it is the statement of the case of the Leicester authorities in a nutshell, and by no unfriendly hand, and by a medical man, let me add, who knows well the importance of vaccination. Here, then, seemed a case calling for investigation and some revision of our severe condemnation of those guardians and town councillors who are unfaithful to their duties as Vaccination Authorities. The threat of a future retribution, however

Digitized by Google

well founded, has little effect on those who enjoy present immunity and think they have discovered a method of proceeding which supersedes vaccination.

In my endeavours to ascertain the real secrets of an immunity which seemed capable of a very different explanation from that given by the anti-vaccination authorities, I have to acknowledge the courtesy of the municipal authorities and the perfection of the sanitary arrangements. I must, too, in passing, pay a tribute to the architect of the Municipal Buildings, as well as to the community whose conception of municipal functions was so high as to raise such structures for their public offices. I must specially thank Mr. Windley, Chairman of the Sanitary Committee, and the medical officers of health, the late and the present, Dr. Johnston and Dr. Tomkins, for an explanation of the system which is followed when a case of small-pox occurs, which is very briefly told. The radical community of Leicester has no compunctions in restricting personal liberty except in the matter of vaccination. They have a law of compulsory notification of infectious diseases, requiring a medical man to report the case as soon as he is aware of it. It is alleged that this law works so well that all the objections of medical men to it have ceased. No sooner is there a case of small-pox reported than the medical officer of health is down upon it with his staff of inspectors. Unless the house is very favourable for isolation, the patient's removal to the Infectious Hospital is urged, and is promptly executed. Not only so, the removal of all the other inmates of the house is pressed strongly. Actual legal powers do not exist. But without these pressure can be applied. If a workman has to be influenced, and is rather rebellious, he is told that his employers shall be informed of the facts of his obstinacy. He is offered compensation for loss of time and loss of property. So with all other inmates. And up to this time all resistance has been overcome, and for ten years Leicester has not had a bad epidemic. And its authorities boast of their promptness and success in carrying out isolation. Disinfection too, is energetically applied to premises and property. I acknowledge that they do this part of their duty well and successfully. Equal success has been attained in other places, notably South Shields, where Dr. Munro reports that in three years and a half small-pox has been introduced thirty-three times, and each first case has been removed to hospital, with the result that in no single instance has there been any extension of the disease after it has been reported to the Health Office. In Leicester there have been occasionally two or three cases among those removed to quarantine. But the success of the system has been great, and undoubtedly goes far to show the desirableness of a general compulsory notification system.

But now I come to another little factor in the protection of Leicester from small-pox, which will surprise plain people out of the profession, and I am persuaded not a few of the good people of Leicester themselves, when they have their minds directed to it. Tell it not in Gath—but it is even so,—Leicester owes its protection, even with all its boasted and really good sanitary arrangements, to VACCINATION! or rather, I should say, to *revaccination*. All the persons in the house of the patient are vaccinated or revaccinated. Every person brought into contact officially with the case of small-pox—the medical officer of health, the inspectors, the nurses and matron of the infectious hospital—are all vaccinated and revaccinated. And I am bold to say that without this protection of vaccination the perfect sanitary arrangements of Leicester would break down in a month. For it is not only that people who are revaccinated never take the disease; but that people who are not revaccinated, who are brought into close quarters with it, do generally take it. Certainly we ought to hear no more of Leicester's independence of vaccination. If her sanitary authorities really believe in their sanitary and disinfecting appliances *per se*, let them put our statements to the test. Let them remove the *cordon* of protected persons about the cases, and their boasted arrangements will prove a delusion; the sick will be without nurses, and the very industry of Leicester will be molested by a plague which will stagger the radical authorities of the borough, and bring the thousands of unvaccinated and unrevaccinated inhabitants to cry for the blessings discovered by Jenner. I need not say that Dr. Johnston and Dr. Tomkins entirely agree with me in this estimate of the part played by vaccination in Leicester. Like most officers of health, they attach great importance to the compulsory notification of diseases; and Dr. Johnston at least is of opinion that with a universal system of this kind, and an efficient and energetic staff for carrying it out, the severity of the vaccination laws might at least be relaxed. Dr. Tomkins lately expressed his views of the urgent need for such a system in the metropolis in THE LANCET of May 2nd, and few could speak with more authority. But it is superfluous to say that they believe in vaccination, and that but for their use of it the authorities of Leicester would be mocked in their boast of mere sanitary precautions. Dr. Tomkins, indeed, is the author of one of the most powerful arguments for compulsory vaccination in the language, read before the Society for the Abolition of Compulsory Vaccination, London.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5704 births and 3033 deaths were registered during the week ending May 29th. The annual death-rate in these towns, which had declined in the preceding ten weeks from 29·3 to 18·7, further fell last week to 17·4, and was lower than in any week since September last. During the first eight weeks of the current quarter the death-rate in these towns averaged 19·5 per 1000, and was 3·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 12·2 in Nottingham, 12·5 in Norwich, 12·8 in Bristol, and 14·4 in Wolverhampton. The rates in the other towns ranged upwards to 25·7 in Portsmouth, 28·7 in Blackburn, 30·0 in Halifax, and 32·8 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 367, 324, and 286 in the previous three weeks, further declined to 278 last week; they included 90 from measles, 76 from whooping-cough, 36 from diarrhœa, 28 from diphtheria, 25 from "fever" (principally enteric), 23 from scarlet fever, and not one from small-pox. No death from any of these principal zymotic diseases was recorded last week either in Norwich, Wolverhampton, or Halifax; whereas they caused the highest death-rates in Portsmouth, Blackburn, Preston, and Bolton. The greatest mortality from measles occurred in Portsmouth, Blackburn, Preston, and Bolton; from whooping-cough in Salford, Sheffield, and Newcastle-upon-Tyne; and from "fever" in Bolton, Portsmouth, and Derby. The 28 deaths from diphtheria in the twenty-eight towns included 20 in London, 2 in Portsmouth, 2 in Birmingham, and 2 in Leeds. Small-pox caused no death either in London or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had steadily increased in the previous nine weeks from 7 to 35, was again 35 at the end of last week; 6 cases were admitted to these hospitals during the week, against 9 and 10 in the preceding two weeks. The Highgate Small-pox Hospital contained 4 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 309, 293, and 282 in the preceding three weeks, further declined last week to 225, and were 70 below the corrected average. The causes of 57, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Sunderland, Leicester, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Derby, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 23·1, 22·3, 22·2, and 21·8 per 1000 in the preceding four weeks, further declined to 21·3 in the week ending May 29th, but exceeded by 3·9 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 9·0 in Greenock and 19·1 in Dundee and Paisley, to 24·7 in Paisley and 27·9 in Perth. The 526 deaths in the eight towns showed a further decline of 12 from the numbers in recent weeks, and included 17 which were referred to whooping-cough, 17 to measles, 7 to scarlet fever, 8 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 3 to diphtheria, and not on

Digitized by Google

to small-pox; in all, 60 deaths resulted from these principal zymotic diseases, against 55 and 44 in the previous two weeks. These 60 deaths were equal to an annual rate of 2·4 per 1000, which was 0·8 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 20, 14, and 11 in the preceding three weeks, rose again last week to 17, of which 16 occurred in Glasgow. The deaths from measles, which had been 17 and 10 in the previous two weeks, rose again last week to 17, and included 10 in Edinburgh, 3 in Glasgow, and 3 in Leith. The 9 fatal cases of scarlet fever, of which 8 were returned in Glasgow, also showed an increase upon the numbers in recent weeks. The 8 deaths attributed to diarrhœa exceeded the number in the previous week by 1, but were 2 below the number in the corresponding week of last year. Of the 6 deaths from "fever," 2 occurred in Glasgow and 2 in Dundee. The 3 deaths referred to diphtheria showed a decline of 2 from the number in the previous week. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 103 and 119 in the previous two weeks, declined last week to 86, which were 1 below the number in the corresponding week of last year. The causes of 63, or 12 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 23·3 and 28·7 per 1000 in the preceding two weeks, declined again to 26·0 in the week ending May 29th. During the first eight weeks of the current quarter the death-rate in the city averaged 26·9 per 1000; the mean rate during the same period did not exceed 18·2 in London and 19·4 in Edinburgh. The 176 deaths in Dublin last week showed a decline of 18 from the number in the previous week, and included 6 which were referred to the principal zymotic diseases, against 14, 8, and 6 in the previous three weeks; 2 resulted from whooping-cough, 2 from scarlet fever, 1 from diphtheria, 1 from "fever" (typhus, enteric, or simple), and not one either from small-pox, measles, or diarrhœa. These 6 deaths were equal to an annual rate of 0·9 per 1000, the rates from the same diseases being 1·5 in London and 2·5 in Edinburgh. The 2 fatal cases of whooping-cough corresponded with the number in each of the preceding two weeks. The deaths from scarlet fever in the city in the first eight weeks of the current quarter were 10, against 20 in the thirteen weeks of the first quarter of the year. The deaths referred to "fever" have shown a marked decline in recent weeks. Five inquest cases and 6 deaths from violence were registered; and 49, or more than a fourth of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable decline from the numbers in recent weeks. The causes of 22, or nearly 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

THE Queen has been pleased to grant Harry Maule Crookshank, M.K.Q.C.P.I., M.R.C.S., Director-General of Egyptian Prisons, permission to accept and wear the Insignia of the Third Class of the Order of the Medjidieh, which His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan, has been pleased to confer upon him, in recognition of his services whilst actually and entirely employed beyond Her Majesty's Dominions in His Highness's Service.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Edmund Humphrey Roberts to be Deputy Surgeon-General, vice W. H. Corbett, M.D., deceased; Brigade Surgeon William Collis to be Deputy Surgeon-General, vice W. H. Muschamp, granted retired pay; Surgeon-Major Samuel Edward Maunsell to be Brigade Surgeon, vice E. H. Roberts; Surgeon-Major William Christy Robinson to be Brigade Surgeon, vice W. Collis. The undermentioned Surgeons-Major are granted retired pay, with the honorary rank of Brigade Surgeon:—Thomas Butler Power O'Brien; Bronislaw James Jazdowski, M.B.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets John Denis Macdonald, M.D., F.R.S., has been placed on the retired list.

The following appointments have been made:—Surgeon John Corshin, to Jamaica Hospital; Surgeon Anthony Kidd, to the *Mistletoe;* and Surgeon J. J. Walsh, to the *Impregnable;* Fleet Surgeon C. Morton, to the *Trincomalee;* and Fleet Surgeon T. L. Burnett, to the Portsmouth Division of Royal Marines.

MILITIA INFANTRY.—5th Battalion, the Royal Irish Rifles: Surgeon Edwin F. Nelson, M.D., is granted the honorary rank of Surgeon-Major.

YEOMANRY CAVALRY (Derbyshire).—Chas. Henry Hough, Gent., to be Surgeon.

ARTILLERY VOLUNTEERS.—1st Cumberland: Acting Surgeon John A. Macdougall to be Surgeon.—2nd Derham (Seaham): Surgeon T. C. Beatty is granted the honorary rank of Surgeon-Major.—3rd Middlesex: Surgeon Richard Davy is granted the honorary rank of Surgeon-Major.

RIFLE VOLUNTEERS.—1st Cinque Ports: Ernest William Skinner, Gent., M.B., to be Acting Surgeon.—3rd Volunteer Battalion, the Hampshire Regiment: Surgeon H. R. Smith is granted the honorary rank of Surgeon-Major.—1st Volunteer Battalion, the Lincolnshire Regiment: Acting Surgeon Edwin William Barton, M.D., resigns his appointment.—3rd Volunteer Battalion, the Norfolk Regiment: Charles Richard Whitty, Gent., M.D., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

MEDICAL DEGREES FOR LONDON STUDENTS.

To the Editor of THE LANCET.

SIR,—I should not venture to add to the already large contributions upon a subject which is practically exhausted so far as argument goes, were it not for the feeling that we are in danger of losing sight of its main issues in aiming at an ideal which it is not possible as yet to attain. That ideal is the consolidation of medical education in London, under the ægis of a real university, which should direct, control, and influence the curriculum, should grant degrees to students trained on its courses, and thereby do much to concentrate scientific and theoretical instruction as distinguished from the practical and clinical. No one will venture to say that this ideal of a Teaching University is at all near to realisation. There are so many conflicting interests to be reconciled, and so much care to be taken to avoid doing an injustice to those who have hitherto had so large a share in education, that it can only be by the slow process of evolution that we shall obtain in London anything like a university organisation. Meanwhile we see, year by year, our students dwindling in number, or breaking off their London career to go elsewhere to obtain that which we are unable to give them; and here it is important to state that a mere title, such as that proposed last night by Mr. Hutchinson, and granted to every doubly qualified man (even with the proviso of passing an additional examination), is not what is desired, nor will it meet the demands of the London student. The remarkable and merited success of the Edinburgh University has rendered such a solution of the question practically impossible. If in London we can establish a curriculum and an examination system which in all respects shall be equivalent to that of the Edinburgh University, then we may reasonably demand that our students should have equal facilities for obtaining degrees as those of Edinburgh. That in some respects we may take a lesson from Edinburgh, and not be ashamed of doing so, must be admitted; just as, I doubt not, there are directions in which even the course at that University may be improved and placed more on a level with London. I cannot, then, agree with Sir Andrew Clark in the statement that the curriculum and examinations of the Colleges are precisely on the same footing as those of the University of Edinburgh; but there is no reason at all why they should not be.

The University of London stands on an admittedly higher level—indeed, the highest; and being, as was remarked the

Digitized by Google

other day in Convocation, world-wide in its scope, it is not to be expected, nor indeed desired, that it should lower its standard to remedy the grievances of those who happen to be educated in the city in which this institution has its local habitation. Even if Mr. Magnus's scheme be carried and the University be brought into more intimate connexion with teaching bodies, it can never meet the grievance which we desire to remedy. Its medical degrees are difficult of attainment; and he would indeed be sanguine who could imagine that it would ever be possible so to raise the general standard of education that every student in London could be put through its curriculum with a reasonable hope of graduation. Why, as it is, a considerable number of those who do enter the London University are compelled to turn away after having fruitlessly devoted one or two years in the attempt to master the subjects of the Preliminary Scientific Examination; and these, be it remembered, are students who have been specially trained in these subjects with a view to that examination. The University of London is, and always will remain, open to but a few, and only a minority of those who enter it will succeed in obtaining its degrees.

Is there no alternative to the London student, or must he be driven to seek a degree elsewhere? Surely, if the Colleges of Physicians and Surgeons could meet this demand by constituting a medical faculty, they would not only revive the prosperity of the London schools, but take a great step forward in raising the standard of education. The demand ought to be that degrees granted by the Colleges should be given after a course of training equivalent to that required by universities. We might have instituted a graduation curriculum which should embrace a certain amount of preliminary science at the commencement, and such subjects as pathology, therapeutics, and public health at the close, over and above the course required for the mere diplomas or title. Students on entry would determine whether they intended to graduate or not, and many doubtless would be well satisfied with the honourable titles of M.R.C.S. and L.R.C.P.; but all would have the opportunity of obtaining the degree if they only worked for it; and those who already hold the two diplomas might obtain the degree after an additional examination. There is little question that the majority of our students would show themselves capable of graduation, whilst a reproach would be removed from London and a greater encouragement given to those who are engaged in utilising the splendid material of London hospitals for the purpose of instruction. Moreover, the Colleges would take a larger share in directing education than hitherto, and a way would be found for realising the ideal embodied in the scheme of a Teaching University.

I am, Sir, yours faithfully,

Weymouth-street, W., June 1st, 1886. SIDNEY COUPLAND.

To the Editor of THE LANCET.

SIR,—I have followed with much interest the whole of the proceedings and correspondence relative to the proposed M.D. degree for those who take the diplomas of L.R.C.P. Lond. and M.R.C.S. So far as I have seen, no direct proposal has been made to cause a retrospective action, without which of course a large class of the medical profession would be left "out in the cold." I feel quite sure that most, if not all, who belong to this class would be perfectly willing to pass an examination in Arts, equal at least in its standard to that required for a "poll" degree: and this being so, as it indubitably is, there can be no valid reason why such a course should not be adopted, inasmuch as it cannot be denied that any man who has been able to pass the ordeal of the two Colleges has been as severely tested, so far as his professional knowledge goes, as a M.B. of either of the older universities or even a "pass" man of the University of London. That the absence of the M.D. degree is no slight drawback is becoming more felt every day by men who never realised its value until their course was too far advanced to permit of their retracing their steps. A short time ago a patient who had recommended a friend to engage me to attend her in her confinement told me that the individual in question had come to the house, but seeing "Mr. ——" on the door-plate, had concluded that I was unqualified, and gone elsewhere. Licentiates of the London College of Physicians are, as a rule, too high-minded to assume a title which is explicitly denied to them by the bye-laws of the institution with which they are proud to be connected, and have to suffer for their honesty by seeing men with inferior qualifications attract the public by the display of the coveted "Dr." on their door-plates. The difficulty might have been avoided years ago had the University of London been sufficiently liberal-minded to recognise medical studies which had been carried on after registration as "medical student," but before matriculation. This would in no way have lowered the standard, the whole of the examinations could have remained the same, and the small indulgence thus allowed would have done very much to bring the University *en rapport* with a large class of hardworking students, who would gladly have gone through the needful steps but for the loss of time and of money which it would have entailed under the existing regulations.

Hoping to see the M.D. of the Medical University of London an established fact ere long, and to be able to avail myself of its facilities, I beg for the present to subscribe myself, Your obedient servant,

May, 1886. L.R.C.P. LOND., M.R.C.S. ENG.

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—For many years you have allowed me at Christmas-time to bring the claims of the British Medical Benevolent Fund before the profession, always with good results. This year is the fiftieth of its existence, and as a jubilee celebration was contemplated, my appeal, with which Sir George Burrows, as president of the fund, desires to be associated, was postponed until it could be made in connexion with that event.

I have now to announce that Sir James Paget will preside at a jubilee banquet to be given at the Holborn Restaurant on July 8th. We are already assured of success, a donation of an altogether unexpected amount having been sent to Sir James Paget, and other important donations having been received, while we have reason to expect that Sir James will be supported by a most distinguished gathering of medical men from all parts of the country. It is true that the jubilee of the Fund falls at a period of great and general financial depression; but while this impairs the power to give, it increases the number of those who are in need, so that we dare not postpone our appeal even if we could put off the celebration till better times. If all who can afford it would give but a little, relief would be carried to a large proportion of the poverty-stricken homes and families of medical men which are brought to the notice of the committee.

The object and mode of operation of the Fund are not even yet fully known. It has two departments: an annuity department, which supports at present fifty-five annuitants, who must be over sixty years of age when elected; and a donation department, which distributes nearly £2000 yearly in sums of from £5 to £20 to meet urgent necessities of broken-down medical men, relieve widows, help struggling daughters, and educate children. This last department is peculiar to the Fund.

No canvassing is required in order to obtain its benefits, with the heart-breaking delay, demoralising exposure, and wearying labour attending this process. Twice a year the list of all applicants over the age of sixty whose cases have come before the Committee is carefully gone over, and the oldest and most necessitous are selected to fill any vacancies which may have arisen. Urgent necessities are still more promptly met, the Committee sitting once a month for the purpose of allocating donations. Another feature of the Fund is that there are no salaries, all the work being done by medical men without fee or reward.

In commending the Fund once more to the favourable attention of the profession, I have only to add that the Honorary Secretaries, Mr. George Field, 13, Wimpole-street, and Mr. Edward East, 18, Clifton-gardens, Maida-vale, will be glad to receive the names of all who desire to help us and to take part in the jubilee dinner.

I remain, Sir, your obedient servant,

W. H. BROADBENT, M.D., Treasurer.

34, Seymour-street, June 1st, 1886.

THE LUNACY ACTS AMENDMENT BILL.

To the Editor of THE LANCET.

SIR,—Superintendents of Asylums in England, with few exceptions, will endorse Dr. Batty Tuke's remarks on the absurdity of sending barristers to inspect asylums, and on the necessity for greater supervision by an increase of the number of medical commissioners. Having been superintendent of a large asylum for fourteen years, I may say that I have never in that time seen an occasion or occurrence which in the least called for a legal visitation, or in which the barrister commissioners were of any legal service. I have had experience of visitation by new legal commissioners, including men whom I esteem and respect, and they, I believe, would be the first to admit that their inspection of asylums during the early part of their appointment was of no value. I entirely agree with the suggestion of resident district commissioners as the only means by which an individual knowledge of the vast number of the insane in England can be acquired by supervisors. An increased number of commissioners would exercise a very beneficial influence on the asylum medical service, by attracting a superior class of medical officers, and the preponderance of the medical element in the commission might depose the legal idea, which at present appears to be dominant, that "detention" is the great object of asylums, in favour of the belief that "treatment" is their essential and most important function. Such changes would greatly advantage the insane, and would tend more than anything else to establish public confidence in the Commission and in asylums.

I am, Sir, your obedient servant,

May 29th, 1886. A MEDICAL SUPERINTENDENT.

ELECTROLYSIS OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—My attention was directed to this subject by Mr. Bruce Clarke some months ago, and as I had a large amount of material to work upon, I determined to investigate the effects of the weaker constant currents upon stricture, in order to supplement Dr. Newman, M. Tripier of Paris, and Mr. Clarke's experiences of the stronger currents upon the same. To my regret, however, I was unavoidably prevented attending the meeting of the Medical and Chirurgical Society when the subject was brought forward, and I venture, therefore, to ask for space for the quota of experience which I had hoped to have furnished to the discussion upon the paper.

The question which I sought to answer was this. If stronger currents burn through the cicatrix and leave a scar, which must necessarily contract, would not weaker currents soften that scar tissue and allow of rapid dilatation? I took twenty cases of stricture at haphazard, all of them of small calibre, some unpassable, varying as to duration from three to twenty years. I subjected each to the influence of from three to four cells, the sittings lasting from fifteen to twenty minutes. With two exceptions, each stream was larger after the sitting, and I could pass a bougie of one size (French gauge) larger than I could before. In two cases the stream was worse. At first I deemed the slight improvement due to the mere pressure of the bulbous electrode against the stricture, but I have since come to the conclusion that weak currents diminish spasm.

Possible danger of reflex shock should be remembered. I quote the only case I have had as yet. Mr. Hichens of Oxford sent me a man with stricture of many years' standing, who, on the application of three cells, had the severest rigor I have witnessed, terminating in profound collapse. Ammonia and water rapidly revived him, and he was able to reach home. Next day I performed internal urethrotomy, which, curiously enough, was followed by no neurotic disturbance. One patient returned with a severe urethritis. So few months have elapsed since my first case was *cured* by means of a *stronger* current, that I do not feel justified in passing an opinion upon it. If the success be honest, then we may expect to do good work with other cicatricial contractions—e.g., of burns, strictures of the œsophagus, pylorus, and other tubes.—I remain, Sir, yours truly,

E. HURRY FENWICK.

George-street, Hanover-square, May 1886.

THE FELLOWSHIP OF THE COLLEGE OF PHYSICIANS.

To the Editor of THE LANCET.

SIR,—All must agree in your recommendation that the teachers in our medical schools, alike in the provinces and London, should be preferred at election to the Fellowship; probably some even while only lecturers, without as yet hospital staff appointment. But, on the other hand, length of hospital experience alone, be it only attendance and not practice, should be recognised by the Council as qualifying for nomination. For, at the present time, excellent clinical workers may never have the chance of becoming either lecturer or hospital physician; the latter appointment now being the reserved reward for lecturing. Yet the clinical student is often not less gifted with powers and taste for original research than his lecturer, and should at least have the Fellowship retained for his goal, if only as a stimulant to further clinical pursuit, which ere now has made the pupil teacher to the master. Hope, Williams, and Bence-Jones, all while *in statu pupillari*, taught to their chiefs at hospital, on their own patients, a later and more recondite science than those seniors had till then acquired; and two at least of the greatest hospital physicians dating between Baillie and Bright—viz., Drs. Chambers and Latham—gracefully owned the sources of such later knowledge. Discouragement and curtailment of independent clinique, by withholding the Fellowship from it, will degrade such students into less responsible specialism, to the loss of more exact medical science. Their work is now the highest. Indeed, their great prototype won *there and then* the true blue riband of the race when, after the best of two years in a fever ward, he interpreted a writing till then undeciphered through ages. I am, Sir, yours truly,

May 31, 1886. A MEMBER PRIOR TO 1859.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SATURDAY.

SATURDAY, the 29th ult., was observed as Hospital Saturday, and great efforts have been made this year to promote its success by making working men more familiar with our local medical charities, their financial position, and their claims upon those whom they benefit. It is believed, therefore, that the fund will be augmented this year—a belief which is increased by the recent visit of Her Majesty, the International Exhibition and other collateral causes tending to an improvement in commerce and trade.

LIVERPOOL AND THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Whilst Birmingham, Leeds, and Manchester have had representatives on the Council of the Royal College of Surgeons in the respective persons of Oliver Pemberton, Wheelhouse, and Lund, Liverpool still remains as it has hitherto been, wholly unrepresented. This circumstance creates, as it very justly may, great dissatisfaction. For many years past Liverpool has possessed in the number and status of its medical practitioners, its medical school, and its hospitals, ample claims for recognition in the Council of the College of Surgeons of England. These claims are now enhanced in the fact that Liverpool possesses a University College in conjunction with the Victoria University of Manchester, while the status of its physicians and surgeons is quite equal to that of other provincial cities, in spite of the disadvantages which Liverpool has had to contend with in being younger in its growth. Mr. Reginald Harrison, surgeon to the Royal Infirmary and lecturer on Clinical Surgery in the Victoria University, is again coming forward for one of the vacancies which will shortly occur in the Council. His election would be a gain to the latter, would be extremely popular to most local and many provincial and metropolitan Fellows, and would remove what is now felt to be a slight to an important medical and surgical community.

THE THORNTON WARDS OF THE ROYAL INFIRMARY.

In these wards Dr. Wallace performed abdominal section in one of those desperate cases which abound here, of

Digitized by Google

neglected ovarian disease for septic peritonitis. The tumour was necrosal and the abdomen distended to its utmost with grumous fluid, the intestines and omentum glued together with a mass bound down over the lumbar vertebræ and the whole peritoneum was covered with lymph. She is now convalescent. Dr. Wallace also did nephrectomy for dilated right kidney, by opening the tumour, the size of a year-old child's head, outside the sheath of the rectus, removing part of the cyst and stitching for drainage in the line of the incision of the remaining portion. Suppression of urine followed, and she died. Dr. Wallace also pointed out a case of hysterical hyperpyrexia, the temperature varying from normal to 108° and even 115°. On Wednesday the same gentleman performed laparotomy for a large solid tumour, which displaced the uterus to the right and filled the pelvic brim. It was found to be a subperitoneal sessile myoma, attached to the uterus to the extent of nearly three inches. It was enucleated, and its cyst stitched for drainage to the lower end of the abdominal incision. The patient is doing well.

COMPULSORY SWIMMING IN SCHOOLS.

The suggestion given in THE LANCET of May 22nd has been favourably noticed in a local daily paper. If the children of the poor in and around Liverpool were more generally able to swim, the number of drowning cases would be greatly reduced. The fondness boys have of bathing is shown by the number seen in the canals and along the sides of the River Mersey, in spite of frequent warnings and fatal examples. No children of either sex should be allowed to venture on the ice until they have learnt the simple and natural art of swimming. The facilities for learning it in this city are ample, and should be better appreciated.

THE ASSIZES.

Among the cases tried at the present assizes was that of the mutineers of the Roman Catholic training ship. One of the officers of the latter received a wound in the chest, which, according to Dr. Main, of Rock Ferry, penetrated the lung, the patient being in great danger for some days. Justice Grantham, who presided in the Crown Court, referred frequently and severely to the number of crimes which had their origin in drunken habits. There were also numerous cases of criminal assaults on females. In one of these the prisoner was under sixteen years of age, and was therefore sentenced to corporal punishment, the judge lamenting that he could not award a similar punishment upon offenders above the age of sixteen.

PRESENTATION TO DR. WATSON OF SEACOMBE.

On the 31st ult., Dr. T. B. Watson, who is leaving Seacombe, where he has been practising for eleven years, was presented with two very handsome testimonials. The first was in the form of a purse containing one hundred sovereigns and a beautifully illuminated address, and was the gift of residents in the neighbourhood. The second was from the inhabitants of Wallasey to the cottage hospital of which Dr. Watson had been medical officer, and consisted of a marble timepiece and ornaments. Some of the principal residents were present, and great regret was expressed at the loss which the district would sustain at Dr. Watson's absence.

THE LIVERPOOL EXHIBITION.

The Shipperies is by no means so devoid of interest to medical visitors as its name would imply. On Saturday last, in what is known as the Indian Village, the visitors had the opportunity of witnessing the performances of the so-called "devil-dancers." These are the individuals called in whom the regular medicine men have failed to cure, and though their gyrations, practised from nine at night until seven in the morning, never produce any favourable result, the natives repose great faith in them as having a great effect upon the soul, even though the patient dies. The Vegetarian Society's restaurant is largely patronised. It is not intended for profit, but for educational purposes, and to show the pleasantness, variety, wholesomeness, and economy of the food products of the vegetable kingdom. Nearly a thousand persons dined here on Saturday, the price of a good meal ranging from sixpence to tenpence. There are also exhibited invalid carriages by Mr. Bell, of Basford, Nottingham, who has succeeded in bringing them to a great state of perfection.

Liverpool June 1st.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE PRUDHOE MEMORIAL CONVALESCENT HOME.

THE annual meeting of this excellent charity was held on the 20th inst. at Whitley. The report for the year exhibited very gratifying results. The financial statement showed that the income of the year had been £3566, the three chief items of which were: subscriptions, £1261; Hospital Sunday Fund, £888 11*s.* 2*d.*; and a legacy from the late Mr. Richard Shorthouse, £500. After meeting all expenses there remained a balance in hand of £78. Dr. Philipson read the medical report, in which it was stated that the total number of cases treated during the twelve months was 1444; of these 486 were from Northumberland, 484 from Newcastle, 463 from Durham, 9 from Yorkshire, and 2 from Cumberland. With regard to the character of the diseases, 1163 were medical and 281 surgical. Of the whole number, 1296 were cured, 102 were greatly benefited, 15 were somewhat better, and 31 were *in statu quo*. Taken altogether, 1413 received benefit, or over 97 per cent.

AMBULANCE WORK IN THE NORTH.

Some fifteen or sixteen years ago the late Dr. Stephens, the surgeon to the Tynemouth Artillery, established an ambulance class. This has been continued with little intermission up to the present. About twelve months ago Dr. Mears, who holds the chair of Anatomy at the Newcastle College of Medicine, took the position of surgeon to the corps. Since then he has devoted much time and attention to the ambulance corps, which is now composed of about fifty members, of whom some thirty are medical students from Newcastle, who have joined the Tynemouth corps owing to the absence of such a body at Newcastle. They were inspected on the 21st instant by Surgeon-Major Irvine, of the Army Medical Department. The class, which is the largest in the country, were put through a rigorous drill by Surgeon Mears. After the examination the inspecting surgeon said, addressing the class, that he had carefully watched the two hours' severe drill they had had, and was highly pleased with all he had seen. On Saturday (the 22nd) an ambulance ceremony took place at North Seaton, at which were present the members who have successfully passed the examinations and attended the course of lectures qualifying them to render "first aid to the wounded." Dr. Clark Newton of Newcastle gave an interesting and concise address on "Ambulance Work." A supper and concert gave variety to the evening's entertainment, and a very fitting conclusion was made by the presentation on the part of the members of the class of a handsome timepiece to Dr. Evers, who had spared no pains in the efficient instruction of his class, and who, in the words of the chairman, had given it every attention "in will and skill."

Newcastle-on-Tyne, May 24th.

EDINBURGH.

(From our own Correspondent.)

PROFESSOR SIR DOUGLAS MACLAGAN.

THE announcement that Her Majesty has bestowed the honour of knighthood upon Professor Douglas Maclagan has created a widespread sense of satisfaction in Edinburgh in very many other spheres besides that of medicine, whilst amongst medical men generally, and especially amongst those *alumni* of the University and the Royal Colleges of Edinburgh who have come in contact with its recipient, this honour is regarded with the greatest personal gratification, as bestowed upon one pre-eminently fitted to sustain it. Sir Douglas Maclagan's honours in connexion with medicine have been both numerous and varied, and his long and brilliant career as a teacher in the Edinburgh School has rendered him in a very special manner representative of medical institutions in this city. But it would give a very partial view of the nature of the feeling elicited by this event were its relations to the medical world alone portrayed, for Sir Douglas Maclagan is as closely associated with the Scottish school of law as he is with that of medicine, and the many-sided nature of his personality is further evidenced

Digitized by Google

by the numerous official or honorary positions that he fills in connexion with various important institutions concerned in promoting the public weal—the advancement of science and national security. By his tenure of the Chair of Medical Jurisprudence in the University, Sir Douglas Maclagan is directly concerned in carrying out the curricula in the Faculties of Law and Medicine. He is President of the Royal College of Physicians of Edinburgh, and was formerly President of its Royal College of Surgeons. By his Vice-Presidency of the Royal Society of Edinburgh and his Fellowship of the Botanical and Chemical Societies he is intimately associated with scientific interests; and he is honourably connected with the public services as Surgeon-General to the Queen's Body Guard for Scotland and Surgeon-Major to the Queen's Edinburgh Volunteer Brigade. He has been a professor in the University for twenty-five years, and previously to that was a lecturer in the Extra-Academical School for eighteen years, and during the whole of his career as a teacher he has been consulted by the Crown authorities in cases of medico-legal importance. As a writer he has attained eminence in two widely different spheres—those of toxicology and therapeutics on the one hand, and of poetry on the other. Many of his songs have become national property, and he is the author of the most popular and best known of our student songs. Add to these characteristics the qualities which he possesses as an eminent physician, a cultured scholar, and a genial and widely esteemed friend, and it will give some explanation of the great feeling of satisfaction which has spread itself through the Edinburgh community generally in regard to Sir Douglas Maclagan's most recent honour.

Edinburgh, June 1st.

IRELAND.

(From our own Correspondent.)

ROYAL UNIVERSITY OF IRELAND.

A MEETING of Convocation will be held on July 27th, to elect two members of the Senate in the vacancies caused by the decease of ex-Archbishop Trench, and the expiration of Dr. Curtis's term of office. As probably Dr. Curtis will offer himself for re-election, one vacancy may only be considered, and for this it may be expected Mr. Farrelly, recently a member of the Senate, will compete. Dr. Knight is not likely to be a candidate on this occasion.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The annual election for President, Vice-President, Secretary, and Council, will take place on Monday next, the 7th inst. It is gratifying to find that the present Vice-President, Mr. William Stokes, the eminent surgeon, will not be opposed for the presidency, notwithstanding a rumour which prevailed lately to that effect. There will be a contest for the Vice-Presidentship, a circumstance greatly to be regretted, Mr. Corley and Mr. Frazer being the candidates. I have already said as much on this subject as is necessary, and shall not again discuss the subject. Mr. William Colles will be re-elected secretary without opposition. As regards the Council, there are twenty-two candidates for nineteen places. A meeting will be held on Saturday next, the 5th inst., to receive the annual report of the Council and discuss any matters that may be brought before the Fellows; and, in the evening the Council and Examiners and their guests will dine together at the College.

CASTLEBRAGH DISPENSARY: CHARGE AGAINST DR. CROKER.

An extraordinary meeting of the dispensary committee was held last week for the purpose of investigating a charge of alleged neglect on the part of Dr. Croker, the medical officer of the district. The case had already been the subject of a question in the House of Commons, and much interest attached to the inquiry. The committee went thoroughly into the alleged matters, and examined several witnesses, including Dr. Gibson, who proved that the case was not of the urgent or difficult character that had been stated. Finally the committee unanimously found that Dr. Croker was not guilty of any negligence in the discharge of his duty.

DEATH OF DR. GRATTAN.

At Drummin House, Carbury, Richard Grattan, M.D., died on May 27th. The deceased was, I believe, the oldest medical man in Ireland, having arrived at the mature age of ninety-eight years. Dr. Grattan was the Senior Fellow of the College of Physicians in Ireland.

COUNTY KILDARE INFIRMARY.

The half-yearly presentment for the support of this useful institution has been thrown out, and the cesspayers may regret their foolish conduct in refusing a grant to a deserving charity. Probably those who have taken an active part in opposing a grant to the hospital may be rather surprised to learn that, by the terms of the lease, the landlord will come into possession of the building directly the infirmary ceases to be used for its present purpose. I have been informed that at a special meeting of the governors held recently, it has been decided to close the institution after the next Kildare Assizes. One cannot but sympathise with the surgeon to the infirmary, who has always performed his duties in a satisfactory manner, and who, for no fault of his own, is deprived of the emoluments of the office he has held for so many years. I may add that the infirmary and residence of the surgeon are held on lease from the Duke of Leinster at a nominal rent of 2½d. a year. During 1885 there were twenty-seven county infirmaries in Ireland, and over 800 beds were in daily occupation; the average cost per head being £37 7*s.* 8*d.*, while the amount levied by presentments last year was £23,643.

The Queen has, upon the recommendation of the Lord-Lieutenant, been pleased to appoint Sir John Lentaigne, C.B., a member of Her Majesty's Privy Council in Ireland.

The vacant surgeoncy in the Mater Misericordiæ Hospital, Dublin, occasioned by the death of Mr. Kilgarriff, has been filled up by the appointment of Mr. Arthur Chance, surgeon to Jervis-street Hospital.

Dublin, June 1st.

PARIS.

(From our own Correspondent.)

THE LATE COLONEL HERBINGER.

A SHORT time before his death, which took place a few days ago, Colonel Herbinger, who was accused of intemperate habits during his field service at Tonquin, for which he was recalled to Paris, where he was summoned before a court of inquiry and honourably acquitted, called on Professor Peter to consult him, as he did not feel very well. Professor Peter states in a note published by him that he was struck with the countenance of the Colonel, which was expressive of profound suffering, and formed in his own mind an unfavourable prognosis. From the oppression evinced by the Colonel when he presented himself before the Doctor, and from other concomitant symptoms, the latter concluded that his malady was not of recent date, and expressed his astonishment that, if he was so oppressed in having ascended only a few steps, he could have supported the fatigues incidental to such an expedition as to that of Tonquin. To this the Colonel replied that when he felt his strength failing him he mounted his horse nevertheless, and ordered his men to watch and support him in case he should fall. At this moment Dr. Peter formed his diagnosis, which, although a posthumous one, is considered sufficient to refute the calumnious charges that were brought against him. "One of the consequences," the Doctor went on to say, "of cerebral anæmia to which the Colonel was subject was the absolute impossibility of his maintaining his equilibrium owing to the attacks that he felt at certain moments of symptoms of giddiness similar to those produced by the abuse of alcohol. Moreover, patients affected in this way wear a purple hue on their countenances, which are also bloated like those of persons whose necks are violently constricted. I am persuaded," added the Doctor, "that these external signs were sufficient to originate the terrible accusation that was brought against Colonel Herbinger." I send you this note that it may serve as a lesson to those who are ever ready to attribute to drunkenness the symptoms above described.

COW BYRES IN TOWNS.

At a recent meeting of the Council of Hygiene a discussion took place as to the advisability of preventing cows being kept in the town, alike on sanitary grounds, and because the milk of the animals so confined is prejudicial to health, on account not only of its deteriorated condition,

Digitized by Google

but of its being often a vehicle for the transmission of tuberculosis, with which the cows so situated are generally affected. No decision had been arrived at, as some of the members present admitted that, although the milk would be much improved by keeping the cows in the country, yet their presence in town is almost indispensable in a certain number of cases, and the risk of infection may be reduced to a minimum if the consumers would only boil the milk before they use it. This risk is considerably less in this country, as the inhabitants seldom or never drink raw milk.

Paris, June 1st.

NEW YORK.

(From our own Correspondent.)

AMERICAN MEDICAL ASSOCIATION.

THIS body met at St. Louis in annual session last week. The chief interest to the profession at large was its action in regard to the proposed International Medical Congress. It was rumoured that the Association would reinstate the old committee, but no such change was made, and the efforts to organise the Congress will continue on the present basis. It should be understood abroad that there is no hostility of the profession in this country to the Congress; but, on the contrary, there is the most cordial feeling in its favour, and it will be well attended.

SPLENECTOMY.

Dr. Polk exhibited a spleen which he had removed from a woman to the Surgical Section of the Academy. The peculiarity of the case was that he was performing Tait's operation, and, instead of finding diseased ovaries, he discovered a tumour lying between the bladder and uterus, which he proceeded to remove. There had been much inflammation about the tumour and many vessels were ligated. When removed, the tumour had so much the shape and appearance of a kidney that search was made for these organs, and both were found in position. It was then submitted to microscopical examination, and found to be a spleen. The patient made a good recovery.

AMERICAN PUBLIC HEALTH ASSOCIATION.

The next meeting of this body will be held at Toronto, Canada, in October, and the programme of the session has already been issued. There is much interest in the provinces in sanitary questions, and provincial boards of health have been organised. The widespread and disastrous epidemic of small-pox last year has intensified the interest of the people on health subjects, and the leading sanitarians have been desirous of having the Association meet with them for the purpose of awakening a more general public feeling in favour of the new health organisation. The meeting promises to be one of unusual prominence in the history of this powerful body.

AMERICAN SURGICAL ASSOCIATION.

This Association has just completed its seventh annual session. One of the most prominent topics of discussion was laparotomy for the purpose of diagnosis, the affirmative being strongly maintained. A proposition was entertained to unite in a congress no less than nine national associations of specialists, with the general title of "A Congress of American Physicians and Surgeons." This Congress is to meet annually at Washington, but each body is to maintain its separate organisation and publish its own transactions.

ANOTHER GIFT FROM THE VANDERBILTS.

The family of the late Mr. Vanderbilt have added another 500,000 dollars to the like sum given by Mr. Vanderbilt to the College of Physicians and Surgeons, making a total of 1,000,000 dollars to this old medical school. A few days since the corner stone of the new college buildings was laid with much ceremony, and it is the intention of the trustees to complete the structure in time for the next session.

THE CARTWRIGHT LECTURES.

This course of lectures before the *alumni* of the College of Physicians and Surgeons was given by Professor Osler of Philadelphia on "Certain Problems in the Physiology of the Blood." The first lecture was devoted to the so-called third corpuscle.

TRAINING SCHOOL FOR ATTENDANTS ON THE INSANE.

The medical officers of the Buffalo Asylum for the Insane have established a school for the training of attendants, and on April 20th a class of graduates, six in number, received certificates. The graduates were all attendants in the asylum, and they passed a very creditable examination.

New York, May 16th.

MEDICAL NOTES IN PARLIAMENT.

Contagious Diseases (Animals) Act.

IN the House of Lords, on the 28th ult., Earl Spencer moved the second reading of this Bill, stating that besides powers of minor importance which were taken by this Bill was that of bringing dogs under its provisions. In view of the prevalence of rabies in the country, Her Majesty's Government thought it very important to extend the powers of the Privy Council in this direction. The Duke of Richmond and Gordon, the Marquis of Huntly, and the Earl of Ravensworth having expressed approval of the measure, the motion was agreed to.

Lea River Purification Bill.

In the House of Commons, on the 28th ult., the Lea River Purification Bill was read a third time.

Metropolitan Asylums Board.

Mr. Stansfeld, in reply to Mr. Sclater-Booth, stated that it has been the practice for the managers of the metropolitan asylums district to have annual inspections of the Leavesden, Caterham, and Darenth Asylums, and the ship *Exmouth*. The chairmen and other influential members of the boards of guardians in the metropolis and representatives of the press are invited to attend on these occasions, and refreshments are provided. The cost of the four annual inspections in 1885 amounted to £245. This is a considerable reduction upon the amount expended in some previous years, and the Board trusts that the expenditure will be still further reduced. These annual inspections are the occasions when the asylums are officially visited by the managers, who are not on the committees for the management of those asylums.

Rating of Lunatic Asylums, &c.

In reply to Mr. Kimber, Mr. Stansfeld stated that he was not prepared to make any statement as to the scheme of local government contemplated by Her Majesty's Government; but he might say that he did not think it would be expedient to attempt to deal with questions as to the rating of particular classes of property in a Bill having for its primary object the constitution of local authorities and the determination of the areas within which they shall have jurisdiction. Such subjects would, he thought, find their more fitting place in a rating Bill. In reply to a further question, Mr. Stansfeld said that he did not expect to bring in such a Bill.

Belfast Main Drainage Bill.

On the 31st ult. a long discussion took place on an amendment to the Belfast Main Drainage Bill, proposed by Mr. Sexton. The amendment consisted in the insertion of a clause assimilating the qualifications of burgesses in the borough of Belfast to the qualification now existing in the borough of Dublin and in the boroughs of England and Scotland. The consideration of the Bill was ultimately adjourned to the 21st inst.

M. Pasteur's Experiments on Cattle.

In reply to Sir R. Paget, Sir U. Kay-Shuttleworth said that the attention of the Agricultural Department had been called to M. Pasteur's investigations regarding the contagious diseases of cattle, and, by way of a first step in the direction suggested by the hon. baronet, instructions had been given to Professor Brown to undertake a series of experiments with the virus of swine fever.

Medical Acts Amendment Bill.

The House went into Committee on this Bill, and clauses up to Clause 6 were agreed to with amendments. On Clause 7, Sir H. Roscoe moved an amendment which would have the effect of giving to the Victoria University and Durham University each a representative on the Council, instead of being linked together to return one member. Mr. F. S. Powell and Mr. Rathbone supported the amendment. Dr. Foster opposed it on the ground that it increased unduly the power of the corporations and universities in the Council as compared with the representation of the profession. Sir L. Playfair said that, although the general sense of the Com-

Digitized by Google

mittee appeared to be in favour of the amendment, he felt bound to adhere to the Bill as it stood. Sir J. Lubbock said his vote would be influenced largely by any information he might receive as to the extent of the constituency in the Victoria University. Dr. Foster supposed that the constituency would consist of from 50 to 100 medical graduates. After some further conversation the Committee divided, and the numbers were—for the amendment, 119; against it, 42.

Obituary.

HENRY MAC CORMAC, M.D.

IT is with sincere regret we have to announce the death of one of the oldest medical practitioners in Ireland. We refer to Dr. H. Mac Cormac, who died at his residence, Fisherwick-place, Belfast, on May 26th. The deceased gentleman, who for many years has been the father of the profession in this town, was born at the beginning of the present century, and had attained the advanced age of eighty-six years. Having studied at Dublin, Paris, and Edinburgh, he took his M.D. degree in the latter University in 1824, and in the same year became a Licentiate of the Royal College of Surgeons of Edinburgh. He then proceeded on extensive foreign travel, journeying first to Africa. He visited the Cape of Good Hope, and went to Sierra Leone by land. During this voyage he had an attack of jungle fever, to which he nearly succumbed. After his return to England, he made a lengthened visit to North America, which he repeated. Soon afterwards he commenced practice as a physician in Belfast, where his abilities and professional knowledge were speedily recognised, as evidenced by his appointment to the post of physician to the Royal Hospital, then known as the Belfast Fever Hospital. In 1832, when the first epidemic of Asiatic cholera visited Belfast, being then only thirty-two, Dr. Mac Cormac was appointed to take charge of the Cholera Hospital, and so thoroughly were his services appreciated at this critical time by his fellow-townsmen that they presented him with a valuable testimonial. He was subsequently appointed visiting physician to the Belfast District Lunatic Asylum, an office which he held up to the time of his death. He soon brought about a marked change in the condition of the inmates by his insistence upon more generous dietary, and it is worth noting that while in all other public institutions during a subsequent attack of cholera death from that malady was but too prevalent, there was not a single death in the asylum. The deceased was also for a time Professor of the Theory and Practice of Medicine in the Royal Belfast Institution, and a Corresponding Member of the National Institution of Washington. For many years he enjoyed an extensive consultation practice, but he gradually became more devoted to literary and scientific study until, about twenty years ago, he relinquished the active duties of the profession, and devoted himself to writing works on a variety of subjects. The topics, however, on which he most insisted were his method of prevention and treatment of consumption and the danger of inhaling prebreathed air. He insisted most strongly on the necessity of the abundance of pure air, as, he writes, "Pure, fresh, untainted air, at all hours, at all times, and in all places, is the one condition with which nothing should be allowed to interfere." He was also a most ardent advocate of active physical exercise in the preservation of health. During his long and busy career, Dr. Mac Cormac contributed most extensively to the literature of medicine, and amongst the works which he produced were: "A Treatise on Stammering," "The Philosophy of Human Nature," "Methodus Medendi, or the Practice of Medicine," "Translation of Antoninus Epictetus," "Aspirations from the Inner—the Spiritual Life," "Metanoia—a Plea for the Insane," "The Nature and Treatment of Asiatic Cholera," "Proposal for the Painless Extinction of Life in Animals designed for Human Food," "Consumption as Engendered by Prebreathed Air" (which reached a second edition and was translated into German, Dutch, and other languages), "On the Prophylaxis and Arrest of English and Asiatic Cholera by Dilute Acids, especially Dilute Sulphuric Acid," "On the Open-air Treatment of Fever and of Febrile Eruptive Maladies," "Synthesis as taking the place of Analysis in Education," "Etiology of Tubercle," "The Conversation of a Soul with God," and "Moral Secular Education for the Irish People." The above contributions show that Dr. Mac Cormac was a man of most versatile genius, and as an evidence of his cultivation it has been stated that he possessed a knowledge of at least twenty languages. At the time of his death he had in course of preparation for his publishers, MSS. on the subjects of "Philology" and "Insanity." He was held in the very highest respect by the inhabitants of Belfast, whose welfare he had always so much at heart: and his death is deeply deplored by his medical brethren, who looked on him as one who, by his broad sympathies and kindly nature, as well as by his brilliant scientific attainments and writings, had done much to raise the status of the medical profession. Dr. Mac Cormac was the father of Sir William Mac Cormac of St. Thomas's Hospital. The funeral took place on Saturday last, when nearly all the medical men of Belfast were present, as well as a large number of the inhabitants.

Medical News.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week:—

BACHELOR OF MEDICINE.—Patrick Colley Pounden.
DOCTOR OF MEDICINE.—John Allman Powell.

ROYAL UNIVERSITY OF IRELAND.—The following degrees were conferred last week at a public meeting of the University:—

DOCTOR OF MEDICINE.—James Bradley, John Lockhart Livingston, Cornelius Bradley, George Browne, James Chambers, George Freud, R. B. Gorsuch, R. Nixon, R. H. Wagner, J. J. Attridge, J. K. Close, E. Curtin, S. H. Dunlop, E. B. Hazleton, George A. Junk, T. A. Kane, L. Lyttle, W. E. MacFeeters, John Menary, William Mulligan, Wm. N. Murphy, A. T. Nash, Joseph O'Connor, Chas. O'Neill, W. J. Richardson, M. J. Robinson, J. T. Shaw, A. E. Thomson, F. E. Townsend, G. R. Young.

BACHELOR OF MEDICINE.—James Donelan, Francis C. Browne-Webber, Bernard Forde, G. F. Ewens, J. J. Tobin.

MASTER OF SURGERY.—C. Bradley, James Bradley, James Chambers, J. K. Close, Eugene Curtin, James Donelan, S. H. Dunlop, J. F. Eagleton, Robert English, John Flynn, Bernard Forde, George Freud, R. M. Griffin, M. H. Hannigan, Daniel Lee, J. L. Livingston, W. E. MacFeeters, John Menary, S. Moore, Wm. Murphy, R. Nixon, John Oliver, C. O'Neill, Wm. Orr, Wm. Richardson, A. Thompson, A. Thomson, F. E. Townsend, R. H. Wagner, G. R. Young.

MASTER OF OBSTETRICS.—C. Bradley, J. Livingston, J. Attridge, J. Bradley, G. Browne, J. K. Close, Eugene Curtin, George Freud, R. B. Gorsuch, Daniel Lee, John Menary, Wm. Milligan, Samuel Moore, R. Nixon, J. W. Oliver, C. O'Neill, W. R. Orr, R. H. Wagner, John Blair, G. Garry, John Lynham, James McEvoy, John Wheeler.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 27th ult.:—

Cross, Robert George, M.R.C.S., Petersfield.
Mitchell, A. Waldegrave, Slane House, Wandsworth-common.
Smith, Robert Bramwell, Pin Mill Brow, Ardwick, Manchester.
Williams, Lionel Henry, M.R.C.S., Beaconsfield-road, Bristol.

DR. ROBERT GEE has been placed upon the Commission of the Peace for the city of Liverpool.

THE annual festival on behalf of the Hospital for Sick Children, Great Ormond-street, was held on the 27th ult. Subscriptions amounting to £1456 were announced.

AT a meeting of the Middlesex magistrates on May 27th, the salary of Dr. Diplock, coroner for the western division of the county, was increased from £800 to £1000.

THE annual meeting of the supporters of the London Temperance Hospital was held on the 27th ult., when a satisfactory report was presented.

A MATINEE in aid of this year's Hospital Saturday Fund is announced to take place on the 16th inst., at the Gaiety Theatre, when occasion will be taken to present an adaptation of Sardou's "Les Vieux Garçons."

ARRANGEMENTS are being made for holding a public meeting in the Holborn Town Hall on the 25th inst., to lay the claims of the hospitals and dispensaries of the district before the people of the metropolis, and to excite public interest in Hospital Sunday. The chair is to be occupied by the Duke of Westminster, and the Duke and Duchess of Connaught are expected to be present.

Digitized by Google

THE sixty-fourth half-yearly election of candidates for the Royal Hospital for Incurables was held on the 28th ult. There were 25 vacancies to be filled, and for these there were 154 candidates.

AT Old Hill, Rowley Regis, recently, a young woman named HANCOX, who is said to be under eighteen years of age, gave birth to triplets—sons. The young mother and children are doing well.

DR. FREDERICK N. PALMER, a well-known Boston physician, jumped overboard with his little grandson from the Boston and Portland steamer *John Brooks*, while out at sea on the night of the 10th ult.; both were lost.

THE annual meeting of the members of the Victoria Institute or Philosophical Society of Great Britain was held on the 28th ult., when an address was delivered by Professor Hull, F.R.S., the director of the geological survey of Ireland.

SINCE the 28th ult., five people have been bitten by rabid dogs in Huddersfield and the neighbourhood. Four have already left for Paris to be treated by M. Pasteur, their expenses being defrayed by public subscription.

A SURGEON at Cheltenham has been fined £10 and costs for making a false declaration on a certificate of death. He stated that he had attended a deceased woman during her illness, whereas he had only seen her half an hour after death.

PRESENTATION.—Mr. Dale, M.R.C.S., L.R.C.P., Ed., has been presented by the members of the Devizes Independent Lodge of Oddfellows, with an emblem and certificate of membership, in token of their appreciation of his services as medical officer to the lodge.

DR. SEDGWICK SAUNDERS, the medical officer of health, reported at a meeting of the City Commission of Sewers on the 1st inst., that during the past week 315 houses in the City had been inspected, and that of these fifteen required sanitary improvement.

BROMPTON CONSUMPTION HOSPITAL.—At the annual court of the governors of this charity on the 27th ult. it was reported that 1955 in-patients, and 13,805 new out-patients had received advice and treatment during the past year. The total income had amounted to £26,222, and the expenditure to £24,780.

THE new sewerage works at Sheffield, which include main sewers throughout the town, and an elaborate series of tanks, machinery, and appliances for purifying the sewage before it is discharged into the river Don, were opened on the 2nd inst. The cost has amounted to upwards of £140,000.

CONVICTION OF AN ASYLUM ATTENDANT.—At the Taunton Assizes, on the 29th ult., Edward Hill, asylum attendant, was sentenced to twelve months' imprisonment for the manslaughter of Frank Barnes, an inmate of the Wells Asylum, whom he allowed to get fatally scalded in a bath.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Professor Henry Power, F.R.C.S., will commence his course of lectures on Monday, June 7th, at 4 o'clock, on the "Diseases of the Lacrymal Organs." The library of the College will be closed on Wednesday and Thursday, June 9th and 10th.

THE MIDLAND MEDICAL BENEVOLENT SOCIETY.—The sixty-fourth annual general meeting of the members of this Society was held at the Grand Hotel, Birmingham, on the 28th May, under the presidency of Mr. C. A. Newnham, who is succeeded by Dr. James Johnston. The directors reported that during the year 1885 £430 had been expended in grants to fifteen annuitants; two of these spontaneously signified their intention not to seek further help from the Society in consequence of the improved state of their affairs. The roll of benefit members is now 268, and the capital of the Society on the 31st of last December was £10,805 0*s.* 3*d.*, which is steadily on the increase. Mr. Bartleet and Sir J. Sawyer were reappointed treasurers, and Dr. Thomas Savage was re-elected hon. secretary; also the following gentlemen were added to the Court of Directors: Dr. Rickards, Mr. H. M. Morgan, and Mr. Priestley Smith.

UNIVERSITY COLLEGE HOSPITAL.—A fancy dress ball in aid of the funds of this hospital, took place at Willis's Rooms on June 1st. The attendance was very large and the room presented a most brilliant appearance. The Lord Mayor and sheriffs testified to their interest in this deserving charity by being present. The company included many persons of distinction in society, and in the military, artistic, legal, scientific, and medical professions. Dancing was continued till the small hours.

HARROGATE SULPHUR WATERS.—On the 29th ult. the first sod of new reservoirs for the storage of sulphur water was turned at Harrogate. The extent of the demand for this class of water may be gathered from the circumstance that no less than 27,000 sulphur baths were given in the year 1884. The scheme inaugurated on Saturday will not only enable this service to be increased so as to supply 35,000 baths annually, but by a device to be adopted the essential properties of the water will be so retained as to add to its usefulness in a considerable degree. The scheme provides for the construction on one site of a series of a dozen reservoirs for the storage of the sulphur water at a cost of about £4000. Each tank will be 20 feet square and 13 feet deep, and hold 31,000 gallons; the twelve thus giving a total storage of 372,000 gallons. The reservoirs will be constructed of brick in cement, and have a concrete foundation, and will be covered over with concrete arches supported upon iron girders. Above this asphalte will be placed, and the whole turfed over so as to present a flat surface.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—A meeting of this Society was held in the rooms of the Medical Society of London on the 27th ult., the President, Dr. Norman Kerr, in the chair. The first paper was by Dr. T. D. Crothers, Hartford, Conn., U.S.A., editor of the *Journal for Inebriety*, on the Sanitary Aspect of Inebriety. Dr. Crothers pointed out the very great influence which inebriety wielded over the general health of the community, by increasing the susceptibility to sickness, and by diminishing the recuperative power, as well as by causing an enormous premature mortality. At the lowest computation, it was reckoned that in the United States 60,000 lives were annually prematurely terminated by personal alcoholic excess. The proportion of crime caused by inebriety was calculated in Canada at 98 per cent.; in New York city at 80 per cent.; and over America generally at 50 per cent. and upwards. Inebriety was a true disease, and must be treated as such. Professor Justus Radius, of Leipsic, read a paper on Delirium Tremens, stating that he had found the plan of giving the patients a hip bath at 91 deg. Fahr. very useful. Two or three buckets of water, at 51 deg. Fahr., were thrown over the upper part of the body. All this was followed by friction with coarse linen. Sleep was thus often induced.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of the Society was held at 53, Berners-street, on May 19th, at 5 P.M., the President, Sir James Paget, in the chair. The death of Dr. Harvey Kingston Owen, a Vice-President, was announced, and a vote of condolence to the family passed. The report of 1885 was read, and showed a decrease of three members on those of the year before, the total number of members being 363, out of a possible 4000. The number of widows receiving grants had increased from sixty-one to sixty-four, and one orphan had been added to the list. The grants during the year had amounted to £3028, the largest sum ever given. The expenses of the year were £220. The receipts during the year had not sufficed to pay the grants and expenses, and the deposit account had been drawn upon to the extent of £103 to make up the deficit. A legacy of £100 had been received from Dr. Nathaniel Rogers, and had been invested in accordance with the bye-laws. The grant of £26 was made to a widow under Law 78. A vote of thanks to the editors of the medical journals for their assistance in making public the objects of the Society was carried unanimously. Sir William Bowman and Dr. Iliff were elected Vice-Presidents to fill the vacancies in the list; and the following gentlemen were added to the directorate: Mr. T. H. Smith, Mr. Merriman, Mr. Vasey, Mr. Hutchinson, Dr. Godson, and Dr. Potter. The best means of extending the Society and of inducing members to join were discussed. The Secretary mentioned the case of a widow who had received for herself and children £2272, her husband having only paid eighteen guineas subscriptions.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BEAN, CHARLES E., M.R.C.S., L.R.C.P.Lond., has been appointed Surgeon to the Devon and Cornwall Ear and Throat Hospital, Plymouth.

BREACH, JAMES H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Fifth District of the Bradfield Union.

COX, A. H. LISSANT, L.S.A., has been appointed House-Physician to King's College Hospital, vice T. G. Lewis, resigned.

CROPLEY, H., M.R.C.S., has been appointed House-Surgeon to the London Hospital.

EAST, CHARLES E., M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital, vice E. A. Hughes, resigned.

EVANS, G. F. W., M.B.Dub., M.R.C.S., L.R.C.P., has been appointed Assistant House-Physician to King's College Hospital, vice A. H. L. Cox, resigned.

GARRY, T. GERALD, M.D., M.Ch., M.A.O., has been appointed Resident Physician to the Ben Rhydding Hydropathic Establishment, vice Dr. Little, appointed Consulting Physician.

GOWING, B. C., M.R.C.S., L.S.A., has been appointed Medical Officer to the Workhouse of the Penistone Union.

HALL, FREDERICK, M.D., has been appointed Honorary Physician to St. Mary's Cottage Hospital, Southampton, vice Knapton, resigned.

HARRIS, JOHN B., M.D., has been appointed Medical Officer to the Postal District of Lower Norwood.

HUBBARD, D. L., M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital, vice E. H. Smith, resigned.

HUGHES, EDGAR, M.R.C.S., L.R.C.P., L.S.A., has been appointed Ophthalmic Clinical Assistant to King's College Hospital, vice J. F. Harries, resigned.

JACKSON, GEORGE, F.R.C.S.Eng., L.R.C.P.Lond., has been appointed Surgeon to the Devon and Cornwall Ear and Throat Hospital, Plymouth.

JACOMB-HOOD, CHARLES J., M.R.C.S., L.S.A., has been appointed Physician Accoucheur's Assistant to King's College Hospital, vice Frank Penny, resigned.

JEULEY, RICHARD, M.R.C.S., L.S.A., has been appointed Deputy Coroner for the Totnes District.

LAVIES, HARRY B., M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital, vice A. Carless, resigned.

O'MEARA, F. A. T., L.R.C.P., M.R.C.S., has been appointed Assistant House-Accoucheur to King's College Hospital, vice C. J. Jacomb-Hood, resigned.

SCHACHT, FRANK F., B.A., M.B.Cantab., &c., has been appointed Physician to the Westminster General Dispensary.

SMITH, FREDERICK OSBORNE, M.R.C.S., L.K.Q.C.P.I., and L.M., has been appointed Surgeon to the Surgical Appliance Society, Finsbury-circus, E.C.

STOOKES, ALEXANDER, M.B., C.M., L.R.C.S., has been appointed Head Surgeon to the Liverpool South Dispensary.

WALKER, NORMAN P., M.B., C.M.Ed., has been appointed Medical Officer for the Dalston District of the Carlisle Union.

WESTBY, GEORGE, M.L. & L.M.K.Q.C.P.I., L.R.C.S.I., has been appointed Honorary Medical Officer to No. 6 District of the Ladies' Charity and the Lying-in Hospital, Liverpool.

WILLS, W. A., M.B.Lond., has been appointed Resident Clinical Assistant to the Brompton Hospital for Consumption and Diseases of the Chest.

Births, Marriages, and Deaths.

BIRTHS.

BOUSFIELD.—On the 28th ult., at Old Kent-road, S.E., the wife of Edward C. Bousfield, L.R.C.P.Lond., of twins (son and daughter).

FARNELL.—On the 28th ult., at The Goffs, Eastbourne, the wife of Henry D. Farnell, F.R.C.S., of a son.

GABB.—On the 28th ult., at Copthorne, Guildford, Surrey, the wife of J. Percy A. Gabb, M.D.Lond., of a son.

GRIFFITH.—On the 26th ult., at Harley-street, W., the wife of Walter S. A. Griffith, M.B., F.R.C.S., of a son.

HULSEBERG.—On the 20th ult., at Maidstone, the wife of Brigade-Surgeon Hulseberg (R.P.), Medical Staff, of twins (sons).

LUNN.—On the 30th ult., the wife of John R. Lunn, F.R.C.S.Ed., Medical Superintendent of the New Saint Marylebone Infirmary, Notting-hill (prematurely), of a son, who survived his birth only a few hours.

PENNY.—On the 25th ult., at Marlborough, Wilts, the wife of Edward Penny, M.D., of a son.

UPTON.—On the 22nd ult., at Medina-villas, Brighton, W., the wife of H. Chrippes Upton, L.R.C.P., of a son.

WARD.—On Feb. 24th, at Pietermaritzburg, Natal, South Africa, the wife of Charles Ward, M.R.C.S.Eng., L.R.C.P.Ed., F.R.G.S., District Surgeon, Umgeni Division, of a son.

MARRIAGES.

ACKLAND—STUBBS.—On the 1st inst., at St. Mark's, Surbiton, Charles Kingsley Ackland, L.R.C.P.Lond., M.R.C.S., to Edith Stubbs, of Maple-road, Surbiton.

BAKER—GLASSPOOL.—On the 27th ult., at All Saints' Church, Southampton, Thomas Baker, M.R.C.S., L.S.A., of Waterloo-Ville, Cosham, Hants, to Laurie Hannah, only daughter of John T. Glasspool, of West Marlands, Southampton.

GARROD—SMITH.—On the 27th ult., at St. Thomas's, Portman square, Archibald Garrod, M.B., M.R.C.P., M.R.C.S., of Chandos-street, Cavendish-square, to Laura Elizabeth, eldest daughter of Thomas Smith, Esq., of Stratford-place, W.

HUNT—VAUGHAN.—On the 31st ult., at Camberwell, Lewis Gibson Hunt, M.D., of Sheffield, to Emma Lydia Flora, daughter of the Rev. James Stuart Vaughan, M.A., Chaplain of Bethlem Royal Hospital.

LANG—STEWART.—On April 15th, at St. John's Church, Ocho Rios, Jamaica, Alexander Morrison Lang, M.B., to Wilhelmina Ann, youngest daughter of James Stewart, Esq., of Shaw-park, St. Anne's, Jamaica, and formerly of the 22nd Regiment.

MEEK—SALVAGE.—On the 2nd inst., at the Wesleyan Church, Roupell-park, by the Rev. Charles W. Prest, brother-in-law of the bridegroom, assisted by the Rev. Wm. Hawken, John William Meek, M.D.Lond., son of the late John Meek, Esq., of Macclesfield, to Emmeline, eldest daughter of Samuel Salvage, Esq., of West Dulwich.

PERKINS—RUMBALL.—On the 2nd inst., at All Saints', Carshalton, Surrey, Alfred Temple Perkins, M.R.C.S., L.R.C.P.Ed., to Emily Kate Rumball, niece of George R. Forster, Esq., of Warwick House, Carshalton.

TRATMAN—PORTER.—On the 2nd inst., at the Parish Church of Westbury-upon-Trym, Bristol, by the Rev. Wm. Cartwright, Vicar, assisted by the Rev. H. H. Streeten, M.A., Frank Tratman, M.B.Lond., L.R.C.P., M.R.C.S., Government Medical Officer of Gascoyne, Western Australia, fourth son of A. R. Tratman, of Berkeley-square, Clifton, Bristol, to Mary Lydia Waltham, only daughter of Christopher W. Porter, of Redland, Bristol.

WEST—WALFORD-GOSNALL.—On the 2nd inst., at the Church of St. John the Evangelist, Fitzroy-square, W., John Arthur West, L.R.C.P., M.R.C.S., to Emma Louisa, younger daughter of J. D. Walford-Gosnall, of Museum-street, Ipswich.

DEATHS.

COX.—On the 23rd ult., at Clifton, Surgeon-General Charles Lindsay Cox, Retired List, H.M. Bengal Army.

JONES.—On the 22nd ult., at Henblas, Bala, Merionethshire, Richard Owen-Jones, Esq., M.R.C.S.Eng., L.S.A.Lond., in his 49th year.

KIRKWOOD.—On the 7th ult., at Madras (suddenly), of fever, Surgeon-Major T. M. Kirkwood, Medical Staff.

MAC CORMAC.—On the 26th ult., at his residence, Belfast, Henry MacCormac, M.D., Consulting Physician to the Royal Hospital, aged 86.

MONTEITH.—On the 2nd inst., at Oak Holm, Parklands, Surbiton-hill, Lowry John Monteith, Fleet Surgeon, Royal Navy, retired, aged 68.

PALEY.—On the 31st ult., at his residence, Addison-road, Kensington (after a short illness), Edward Paley, M.R.C.S., in his 61st year.

WARD.—On April 17th, at Pietermaritzburg, Natal (after fifty-two days' illness), of enteric fever, phlebitis, and pyæmia, Dorothea Agnes, the beloved wife of Charles Ward, District Surgeon, Umgeni Division.

WARD.—On April 29th, at Pietermaritsberg, Natal, Reginald James Yorke Ward, son of Charles Ward, District Surgeon, Umgeni Division, aged two months and five days.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, June 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 3 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Henry Power: On the Diseases of the Lacrymal Organs.
ROYAL INSTITUTION OF GREAT BRITAIN.—5 P.M. General Monthly Meeting.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Communications from Messrs. S. J. Hutchinson, W. St. George Elliott, and A. Morton Smale.—Mr. T. W. Groves: Practical Microscopy in application to Odontology.

Tuesday, June 8.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Arthur Gamgee: The Function of Circulation.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Chavasse: On a case of Multiple Neuromata.—Dr. Angel Money: Some Statistics of Pneumonia, with especial reference to the Relations of Delirium and Temperature.—Dr. Gervis: A case of Extra-uterine Gestation.

Wednesday, June 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Henry Power: On the Diseases of the Lacrymal Organs.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. F. R. Cheshire: Device for the Better Examination of Bacteria in Culture Tubes.—Dr. E. M. Crookshank: On Photomicrography.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. Thorne Thorne: The International Sanitary Conference of Rome, 1885.—Mr. Bolton G. Corney: The Recent Prevalence of Cerebro-spinal Fever among Polynesian Immigrants.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown. Dr. Grigg: Pyosalpinx in the Puerpera.

Thursday, June 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Professor Alexander Macalister: Habit as a Factor in Human Morphology.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. (1) Mr. S. Snell: Embolism of the Central Artery of the Retina occurring in a case of Puerperal Septicæmia; (2) Cholesterine in a case of Detached Retina.—Mr. R. Brudenell Carter: (1) Case of Foreign Body embedded innocuously in the Retina; (2) On some Points in Cataract Extraction.—Mr. W. O. Maher: (1) A Rare Case of Exophthalmic Goitre; (2) Case of Retinal Detachment.—Dr. Stephen Mackenzie (for Dr. Davidson): Fatal Meningitis after Enucleation.—Mr. J. B. Lawford: New Tissue Formation in Choroid and Retina. (Living and Card Specimens at 8 P.M.)

Friday, June 11.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Henry Power: On the Diseases of the Lacrymal Organs.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Professor Dewar: Meteorite Problems.

Saturday, June 13.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. G. G. Stokes: Light, with special reference to Effects resulting from its Action on Various Substances.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

TEREBENE RASH.

REFERRING to the case of terebene rash published in our issue of the 22nd ult., Mr. Lascelles Scott has written describing a similar rash produced on himself after the use of a certain sample of terebene, other specimens having been used without any inconvenient result. Upon examination the sample was found to contain a little admixed or unaltered turpentine, a resinous body, and a comparatively large quantity of peroxide of hydrogen. The natural inference is that the rash is produced not by the terebene *per se*, but by some impurity existing in the particular sample employed. Mr. Lascelles Scott concludes by expressing the opinion that all terebene for medicinal use should be carefully tested, and all that is not free from H_2O_2, unchanged turpentine, and dissolved resin should be rejected.

Dr. F. P. Atkinson.—The battery can no doubt be obtained through any first-class philosophical instrument maker.

"A ROUGH-AND-READY MEDICAMENT."

To the Editor of THE LANCET.

SIR,—The reference which Dr. Curran asks for in your last issue is to be found in Baron Larrey's "Mémoires et Campagnes," vol. iv., p. 237. The incident occurred to Marshal Lannes during Napoleon's advance into Spain—not during the retreat from Moscow. His horse having fallen with him whilst crossing a mountain range near Tolosa, the Marshal sustained several severe and dangerous bruises. He was at once wrapped in the warm skin of a newly slain sheep, and was able in two days to resume his command. This must be regarded as a rough-and-ready method of applying the wet pack. With regard to the question whether this practice is to be found among "primitive or remotely situated people in our midst," the custom of Highland seers, up to a late period, of wrapping themselves in the hide of a recently slaughtered bull may be mentioned. This was, however, for distinctly prophetic purposes; I am not aware that it was employed by them for medical purposes. But with primitive people medicine is rarely divorced from religious practices, and the bull's hide might be found to be as powerful a physical as it was a spiritual stimulant.

I am, Sir, yours truly,

May 31st, 1886. CHARLES H. RALFE.

To the Editor of THE LANCET.

SIR,—In some editions of Druitt's Surgery Dr. Curran will find an account of how Marshal Lannes was resuscitated by being wrapped in a sheep's skin in one of the passes of the Pyrenees after exposure to cold.

I am, Sir, yours truly,

June 1st, 1886. A SURGEON.

MEDIÆVAL MEDICINE.

F. A. (Leicester).—It was not till the last three centuries before the Renaissance that the distinction between physician and surgeon became commonly recognised. The distinction arose from the special instruction in the two great departments of the healing art that began to be given in the schools, the official title to practise being that of "Master," while the official title to teach was that of "Doctor." Empirics, particularly in minor surgery, were then in great request, and between them and the officially qualified there was continual war. It was then, too, that, according to Dr. Chiappelli, whose work on Mediæval Medicine may be recommended, there arose specialists, such as "ocularii," "vulnerarii," &c., whose ranks were often reinforced by women, to whom diplomas were given by such schools as those of Naples, Florence, Bologna, and Venice. In process of time Corporations, with the sanction of the several States, were formed, to guard the rights and interests of the profession, and we find everywhere penalties more or less grave attached to the illicit practice of the healing art. At Naples, for example, a fine of 200 lire (£8) was exacted from the apothecary who received the prescriptions of an irregular practitioner. The connexion between medicine and law was at first slight; only at Venice the medical man was obliged to report cases of wounding and suspicious death; and, later, courts of justice called in physicians and surgeons as experts, and also to tend the sick in prison, to assist at tortures, and even in some cases, notably at Florence, to direct them. The public authority, however, provided medical assistance to the poor, compelling it to be given gratuitously, but gradually coming to remunerate it out of the civic chest. Fees varied with different localities. At Pisa, for example, the statutes assigned for a medical examination in official cases from five to ten soldi (from 2½*d.* to 5*d.*). At Milan the College of Physicians fixed the sum of from ten to twenty soldi for each day's visit during the plague. The consultant was more handsomely rewarded than the physician in attendance. Communes paid their medical officers either in stipulated sums or their equivalent in kind, according to the service done; but at Courts there was no limit to what the surgeon or physician might receive. Clerics and Jews in the earlier mediæval time had the monopoly of practice, because to the laity study was made impossible by barbaric turbulence, while the priests had readiest access to the sick and wounded. But their power was often so abused that the Church had to prohibit its exercise. The influence of the Jews, again, originated in their reputation for skill in Arabian science, and in their case also the Church, not with complete success, interposed its veto. The attitude of literature to medicine was in those days hostile, according to Dr. Chiappelli, who explains it by the antagonism then prevailing between physicians and men of letters, the latter maintaining idealistic aspirations nourished on the classical Renaissance, while the former adhered to the positive and material tradition, especially of the Arabian schools. It was reserved for a more enlightened age to bring the two into harmony.

Nurse.—A letter addressed to the Secretary of the Society, 53, Berners-street, will meet with attention.

THE DEGREE OF LOUVAIN.

To the Editor of THE LANCET.

SIR,—Under the above heading, in your issue of May 22nd, occurs the following: "A medical man with British diplomas thinks it is a great mistake.....to propose that foreign diplomas shall be registered, especially considering how easily these foreign diplomas are obtained." I will not attempt to deny that there are on the Continent (as is also the case in the United Kingdom) some schools whose diplomas are held in less esteem than the degrees of other establishments; but to hold forth that foreign diplomas, as a rule, are *now* easily obtained is running very wide of the mark. I will only say this, that if the "medical man with British diplomas" will come over here in July or February to investigate the curriculum, and take notes of what he hears at the six theoretical and several practical examinations in science, medicine, and surgery (all of them public) required for the "M.D." degree, his opinion as expressed in THE LANCET will be very considerably modified—at least, as regards the old University of Louvain, whose "M.D." I am hoping to complete next year. I might ask, *par contre*, whether the free advertising in English medical papers for unqualified men to "visit, dispense, and attend midwifery" is calculated to add, in the eyes of foreigners, to the value of, or even the necessity for, a qualification in England.

I am, Sir, yours faithfully,

Louvain, May 26th, 1886. A FOREIGN STUDENT AND SUBSCRIBER.

"SUMMER RAMBLES IN MY CARAVAN."

A PLEASANT paper is that supplied by Gordon Stables, M.D., R.N., to the *Leisure Hour* from month to month; full of vivid description of place and people, with bits of quaint humour here and there, and telling anecdote. The article is calculated to enhance one's love of British hills and dales and breezy moors. Dr. Stables should have many imitators in his method of spending a holiday.

G. G.—We cannot assist our correspondent in the matter.

THE FORM OF THE DENTAL ARCH.

AFTER carefully examining and measuring the mouths of more than two hundred persons, Dr. Dementyeff has come to the conclusion that the normal form of the dental arch is elliptical in the upper jaw, but paraboloid in the lower, the internal corresponding with the external arches. These normal forms were, however, only found in 50 per cent. of the cases. A link between the normal and abnormal forms is supplied by the straight jaw, which occurred in 18 per cent. of the cases examined. Carious teeth were observed in 50 per cent. of the jaws examined, the proportion of disease being distinctly higher in those of abnormal form.

An Assistant (Essex).—When an assistant gives evidence he does so in his capacity as assistant. He is entitled to his expenses, and, if he does his work well, perhaps to share the fees; but he cannot claim them as a matter of right.

M.D. Erlang.—1. The degree mentioned is registrable, and stands on the same footing as the corresponding degree in other universities.—2. Yes, but the selection of the particular corporation must be left to our correspondent.

HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—The brilliant discovery of M. Pasteur has one important drawback: it is a delicate and difficult process, only to be carried out by an expert, and in an institute specially arranged for the purpose. May not the process be simplified, and the same result be obtained by a less complicated method? Rabies and hydrophobia are unknown in this part of the world; and though a recent traveller has described both diseases as being common in Dammarsland, no case of either disease has ever been known to occur either in the Cape Colony or in the adjoining States. Experiments are therefore impossible here. It is well known that certain virulent diseases differ very greatly in their degree of intensity, according to the channel by which they are introduced into the system. Small-pox by inoculation is much milder than the disease taken in the ordinary way, whilst affording equal protection. So, again, with the pleuro-pneumonia of cattle, inoculation has been largely and successfully employed to induce a milder form of the affection; but in this part of the world the latter process has been entirely superseded by the practice of administering the pleuritic fluid itself by the mouth. On the appearance of the disease in a flock, the sick animal is at once slaughtered, and the carefully strained pleuritic effusion administered to all the healthy members of the herd. In this way a form of disease is induced which is even milder than that by inoculation, and at least equally protective. Now, it does not seem unreasonable to suppose that something of the same sort might be done in cases of persons bitten by rabid dogs—that the morbid saliva might be given by the mouth to such persons as soon as possible after the injury, and repeated for several days, the form of administration being pills, to prevent the possibility of absorption by slight wounds of the mucous membrane. In this way we might expect a slight but protective form of the disease to take place. Nor is this altogether novel. Amongst innumerable suggestions for the cure or prevention of hydrophobia at various times, a hair taken from the muzzle of the diseased dog has been recommended to be swallowed by the patient. Such a hair would be saturated with saliva. Whether this treatment has ever been successfully carried out I cannot say. At any rate, the idea has survived in the well-known phrase, "A hair of the dog that bit you."

I am, Sir, yours obediently,
Cape Colony, May, 1886. M.

CONSULTING AND GENERAL PRACTITIONERS.

W. H. K.—The duty of a consultant undoubtedly is to refer his patient to his ordinary medical adviser, with undiminished respect for his services. If it is not the rule of the profession, so much the worse for that high order of practitioners by whose ethics and *morale* in past times the whole tone of the profession has been sustained. We can only advise practitioners to note those consultants who do not act up to this rule, and to have no company with them.

Mr. W. F. MacDonogh.—Such a distribution of cards would be professional advertising, and decidedly objectionable. Our correspondent will see at once that it would be a suggestion to the patients of other medical men.

SPINA BIFIDA.

To the Editor of THE LANCET.

SIR,—I agree with Dr. Morton that the remark in the *Dublin Medical Journal* of March last concerning the hopelessness of cases of spina bifida should not pass unnoticed. Besides several cases cured by excision of the sac reported previously and several unpublished, only to-day I dismissed cured a child three months old operated on three weeks ago. Recently Mr. Pridgin Teale excised a sac in the cervical region, effecting a perfect cure; and a short time previously my colleague, Mr. Ward, successfully excised one in the lumbar region. Although Dr. Morton's method by injection differs very materially from mine, which is a plastic operation, undoubted cures have been effected by both plans, and it is not affirming too much to say that in by far the greater number of cases of spina bifida the prognosis is good if an operation be properly performed.

I am, Sir, yours truly,
Leeds, May 11th, 1886. A. W. MAYO ROBSON.

PRACTICE IN CANADA.

A Toronto University Man has favoured us with the following information on a matter on which questions are frequently put to us:—"Before being legally qualified to practise in the Dominion it is requisite that the diploma of the College of Physicians and Surgeons (Quebec or Ontario) be obtained. If a British diploma covers examination in medicine, surgery, and obstetrics, on presentation of the same with good credentials, and on payment of the fee, $5, the licence will be granted without examination; if one subject has been omitted, a candidate must undergo examination in that subject. If he decides on practising in the province of Quebec, on arrival at Montreal he should call on Dr. Campbell of Beaver-hill, who is the secretary, and will give him every information. Appointments other than hospital are, I believe, in the gift of the Dominion or Corporations, and for a stranger to expect to get one on arrival will only lead to disappointment. Appointments there, as in this country, require private influence. A general practitioner's position in Canada is invariably much better than in England. He takes a social standing there, and is respected and looked up to by his patients, provided he respects himself. Bad debts are the exception. If patients are poor, the practitioner must make his accounts to meet their circumstances. This consideration will be appreciated. If a practitioner has in England descended to sixpenny or shilling dispensary work, he must not think of continuing it in Canada. A few of the lower class would perhaps accept his services, but the respectable working classes would despise him, and medical men would treat him as beneath their contempt."

Mr. Thomas Williams.—We are quite satisfied with our first answer A medical man would do a very questionable service to his patients by directing their attention, or that of their friends, to all the possible diseases which they might develop.

Marishal is referred to our Students' Number, published in September last.

IODOFORM SPRAY.

To the Editor of THE LANCET.

SIR,—In the different articles on the use of iodoform I do not remember any allusion having been made to its use in the form of spray, although for a long time I have supposed in many conditions of throat affection, and perhaps even pertussis, it might be so used advantageously; lately, however, I have employed it in many cases, and have been struck with the rapidity with which it often gives marked relief. The ether in which it is dissolved appears to immediately constringe the congested capillary vessels, while the iodoform being deposited in a thick film is more efficiently applied and retained longer, and by its sedative influence continues to relieve the tension and engorgement, as an instance of which I give the following case.

On Tuesday last a man, a carpenter by trade, consulted me. He said he had been shivering all day at the bench (he looked very ill), and had some aching pains over the body, especially the back, and the throat was very sore; on examining which I found the whole fauces, uvula, &c., bright-red and slightly swollen; pulse 110, temperature 102·5°. I advised him to declare upon his club at once, as I thought he would require at least a week's rest. I well sprayed his throat, and he expressed himself immediately as feeling relieved. I gave him also some mindererus and a Dover's powder to be taken at night. Next day he called upon me, saying he felt quite well, and that his sore-throat was quite relieved. I have used iodoform mixed with sugar, benzoate of soda, and other ingredients, applying it by means of a camel-hair brush; but as it is often difficult to get it to adhere, I consider the spray much more efficacious. I use a spray bottle, which I can use with one hand and depress the tongue with the other.

I am, Sir, yours faithfully,
May 26th, 1886. GEO. MUNDIE, M.D.

AFGHAN ZOOLOGICAL COLLECTION.

BY permission of Professor Flower, the zoological collection made by Brigade-Surgeon Aitchison, C.I.E., lately attached to the Afghan Delimitation Commission, is to be for a short time placed on view in the South Kensington Department. The collection will, we understand, ultimately be sent to India, and distributed amongst various museums in that dependency.

Mr. W. Gibson Bott.—There appears to have been misinterpretation on both sides, and no real cause for unpleasant feeling.

Professor Ray Lankester.—Too late for this week.

A. R. C.—From 10*s.* 6*d.* upwards, according to sum assured.

A CORRECTION.

To the Editor of THE LANCET.

SIR,—May I ask you to correct two misreadings in the explanations attached to the temperature chart of my article on Rheumatic Hyperpyrexia, which appeared in your issue of last week. Line A and Line F, for "given twice" read *given every two hours;* Line B and Line C, for "given four times" read *given every four hours.*

I am, Sir, yours truly,
Birmingham, May 31st, 1886. ARTHUR FOXWELL.

CHOLERA: ITS INVESTIGATION AND TREATMENT.

A CORRESPONDENT writing from Tangiers says:—"I believe myself to be on the eve of discovering a specific for cholera; but to enable me to carry my investigations to a close it is necessary for me to see some more cases of the disease. As, however, my means will not permit me to leave my practice here for any considerable length of time, I write to ask you if there is any fund available that would furnish me with the necessary money to carry on my investigations in Spain should cholera reappear there this summer. As I am a married man with a family I cannot sacrifice my practice to carry on investigations respecting cholera and its treatment unless I am compensated for so doing by my expenses being paid."

Acarus might apply to one or other of the firms whose announcements appear in our advertising columns.

Mr. Mason should consult his usual medical attendant. We do not give advice.

RINGWORM IN NEW-BORN INFANTS.

To the Editor of THE LANCET.

SIR,—Your correspondent, "M.B. Oxon.," alludes to the question of the intra-uterine existence of ringworm. Our knowledge of the conditions of intra-uterine life negatives the likelihood of such an occurrence, and clinical observation confirms this view. The earliest age at which I have seen ringworm in an infant is nine days. In this case there was a well-defined ring, involving part of one upper eyelid, eyebrow, and adjacent skin of the forehead, and the diagnosis was confirmed by the microscope. Other children of the same family had ringworm at the time, and I can see no reason to suppose that this infant was not infected in the ordinary way. In after-life the possibility of the existence of ringworm is not so defined. In children and young people it may be met with in almost any position. It may occur at any age on the less hairy portions of the skin and in men's beards. On the scalp it is rare in adults in its ordinary forms. I have seen well-marked ringworm in three cases in this position. The first case was that of a woman sixty years of age, a large portion of whose scalp was the seat of a vigorous development of the disease; the second that of a lady of thirty-five years, who had acquired it in India three years before I saw her, when I found evidence of the complaint over the occiput; and the third that of a lady of twenty-six, who had had charge of a child similarly affected.

I am, Sir, yours truly,

Savile-row, W., June 1st, 1886. WYNDHAM COTTLE.

WILD BEASTS AND SNAKES IN INDIA.

DURING the past year wild beasts and snakes have been unusually destructive to human life in the central provinces of India, there having been an increase of 262 in the number of persons killed, as compared with the preceding year. Of wild beasts, tigers, of course, were the most destructive, their victims numbering 110, as against 98 in 1884, while the number of tigers killed was only 221, against 260. The deaths from snake-bite last year amounted to 1666, against 797 in 1884, while only 1997 snakes were killed, as compared with 2378. In an official note on the subject it is observed that there has been a "satisfactory increase" in the number of wild animals killed; but this increase is due to the larger number of bears, wolves, and hyænas destroyed.

Africanus.—The position is not a dignified one, and should be declined.

M.D.—It is a matter of individual taste.

JOHNSON'S LECTURES ON BOTANY.

To the Editor of THE LANCET.

SIR,—I shall be obliged if any past or present Guy's man can tell me whether the "Key to the Botanical Orders," in green paper cover, by Mr. Johnson, late lecturer on botany at the hospital, is still in print; and, if so, where it may be obtained. I am, Sir, yours faithfully,

June 1st, 1886. E.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

CORRESPONDENTS, LETTERS, &c., have been received from—Mr. Godlee, London; Dr. Coats, Glasgow; Dr. Broadbent, London; Dr. Brailey, London; Dr. Brodie, Detroit; Dr. E. W. Symes, Halifax; Prof. Ray Lankester, London; Mr. W. G. Bott, London; Mr. T. C. Jones; Mr. Blackett, London; Mr. Essex, Pontypool; Messrs. Gilson and Co., London; Dr. Pearse, Haslemere; Dr. Collins, London; Dr. James Gairdner, Crieff; Mr. W. Grant, London; Mr. Lascelles-Scott, Forest Gate; Dr. Ralfe, London; Mr. F. W. Lowndes, Liverpool; Mr. Hurry Fenwick, London; Dr. Swann, Batley; Mr. Pratt, London; Mr. Fuge, Taunton; Mr. Hambly, Bristol; Mr. Shanks, London; Messrs. Ingleby Lectures
ON
SOME FUNCTIONAL DISORDERS OF FEMALES.

By WILLOUGHBY F. WADE, F.R.C.P.,
SENIOR PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

LECTURE II.

THE preliminary stage of the reproductive cycle includes, as I have said, the whole life of a woman antecedent to marriage. The hope of marriage, or if not the hope the idea of its possibility, is never quite extinguished in the female breast. And it must be confessed that events occur from time to time which afford sufficient justification for this tenacity. Disappointment in the realisation of these hopes produces different effects upon different mental constitutions. In some cases it produces a hardening and deleterious effect upon the character; in others, it ripens and intensifies all the most beautiful and charming qualities of the woman. We may say that, if it takes a good woman to make a good wife, it takes a still better to make a good "old maid." Yet it is but simple justice to say that examples of both classes abound, fortunately for it, in the world.

The appearance of the most striking evidence of puberty, the catamenia, is rather the beginning than the end of those changes of body and mind which result in the production of the woman. We may be permitted to imagine the body divided into that which is nervous system and that which is not. Of these two parts, it is the former which chiefly, that is essentially, differentiates the woman from the man; which most clearly justifies the statement that the key to the difference between the two sexes is only to be found in the different part which each has to play in the business of continuing the species. The quickness of perception, the rapidity, and within limits the accuracy of interpretation, the ready responsiveness, the too often fatal, but always interesting credulity—all these are necessary to the successful transaction of the instinctive business of her life, the attraction and retention of an admirer, the detection and annihilation of a rival. Nor is there any incongruity between the higher qualities of the mind and the lower or quasi-instinctive ones.

Any adequate discussion of this subject would absorb more time than we have to spare. If it interest you, study it for yourselves in the book of Nature. For yourselves, but not by yourselves; take for your guides and teachers the great masters and mistresses of fiction. I need not enumerate those whose genius has enabled them to penetrate and portray the innermost workings of the heart. All afford materials which may assist you in your research, for "the truest tales are not those which really happen." All, even the most antipodal—as amongst living authors the American Howells and the French Zola—can tell something of the workings of the human mind, as affected by the conditions under which it operates. Thus we may learn that the passions, like bacilli, can be malignantly intensified or usefully attenuated, according to the medium in which they are developed. If the attenuation is carried to the point of uninfectiveness, the form may remain the same, but the vital characteristics are abolished.

We are told in a pungent modern satire, acidulated no doubt by the unhappy personal experiences of the author, that in "the coming race" woman will claim the privilege, now "usurped by men, of proclaiming their love and urging their suit—in other words, of being the wooing party rather than the wooed." This gibe is not altogether gratuitous; but, nevertheless, we should all sympathise with, and according to our opportunities further the intellectual elevation of, the other sex—if on no other than selfish grounds, and for the purpose of perpetuating the ascendancy of our own sex; for we know how often and in how large a degree great men are indebted for their superior powers to their mothers. It is not art, but Nature providing for the continuation of the species, that has framed the minds and bodies of the race; that has implanted in each sex those peculiarities which are responsible for things as they are, and, for the most part, must continue to be. But it must be repeated, this is no justification for artificially intensifying these differences; nor is it any reason why the higher powers of the female mind should not be educated, with the view of fortifying them by cultivation. No sensible person would assert that all men are superior, either physically or mentally, to all women. On the other hand, few would deny that in both these respects the average of man is higher than the average of woman, or that the highest man is higher than the highest woman. I have already referred to those qualities which are by common consent accepted as being peculiarly characteristic of the female mind; these are acuteness of perception and rapidity of interpretation. The woman sees many things which pass before a man's eyes unperceived; or, if perceived by both, the woman's conclusions are drawn instantaneously. The man revolves the circumstances in his brain, comes to a conclusion more slowly, and often less correctly. We have here, as it seems to me, the key to many of the functional disorders of women. The same peculiarity characterises the structure of the whole nervous system, from that of the highest centres of the brain to that of the lowest ganglia of the sympathetic system. This difference in structure is not discoverable by anatomy, however minute. It is by its fruits that we know it. Sensitiveness to impressions, or excitability; facility of transmission of these impressions from one centre to another; this we may be permitted to call "permeability"—a clinical phenomena which has not received due attention, and which I venture to call "the radiation of pain," may be cited in illustration of this permeability. The following cases, which I quote as examples of radiation of pain, are worthy of consideration, even by those who may not be prepared to accept my theoretical explanation of them.

Some years ago my opinion was requested in regard to a lady, aged about thirty-two. She had been for a good many months under medical care for general and somewhat indefinite ill-health. For some weeks previous to my visit pains about each subclavicular region and a dry cough had raised fears in the minds of her medical attendants that she might be becoming consumptive. My examination confirmed the opinion previously entertained, that no physical sign of lung disease was to be discovered. We all know that many patients are extremely loth to let us get away from the consideration of an existent pain to that of any other symptom. She was of this class. It required, therefore, much insistance to elicit the following facts: Before the pain attacked the subclavicular region there had been a zone of pain round the middle of the chest; previous to that a similar zone round the lower part of the chest and the upper part of the abdomen; that in its turn had been preceded by pain occupying the middle third of the abdomen; and then we found that the original seat of the pain had been the two hypogastric and the pubic regions. It came out that, though her attention had been engrossed by each new development of pain, those previously existent had never entirely subsided. This history suggested that perhaps, after all, the disorder had a uterine origin; and so it turned out. On examination, we found that the os uteri was extremely tender, and also, as it was then termed (for it was a good many years ago), ulcerated. This condition was in a short time relieved by local treatment, and, coincidently, all her pains and the cough disappeared, and she was restored to health.

It may not be disadvantageous to diverge here for a moment from our immediate subject, and interpolate a few words upon a very important topic. This is the relation of such a lesion as that just mentioned to the symptoms described, and more especially to the earlier symptoms. A very large number of female cases may be resolved into three groups or categories. The first comprises local lesions, such as the one above mentioned, and flexions, versions, and fibroids accompanied by pains and irritations in or near the lesion. In the second group, we find the same lesions, but unaccompanied by any symptom whatever. Whilst in the third we put cases with similar symptoms, but without any discoverable local lesion. Experience has taught me that by treatment not a few cases may be removed from the first class into the second—that is to say, that the symptoms complained of may be removed, though the anatomical changes remain precisely what they were. In one case the treatment required may be, as in the one quoted, local; in another, it may be directed to the part or parts secondarily

Digitized by Google

affected; whilst in a third, it may be of a purely general character, aiming, for example, at the correction of some disturbance of the blood-forming or blood-purifying organs, or, which may or may not be the same thing, those of complex conditions, which we term gout or rheumatism. It seems to me equally true that cases may, by influences sometimes traceable, at other times mysterious, be removed from the second class into the first. In other words, the anatomical lesion may, in any case, be at one time latent, and may at other times manifest itself by symptoms, and such alternations may recur with indefinite frequency. In saying this, we are admitting that the symptoms are epiphenomena, caused by or arising out of the gross lesion; and this I believe to be in some instances true. But on the other hand if we admit, as I contend we should, the existence of similar symptoms without any gross lesion, then probably in some cases the concomitance of symptoms with such lesions is purely accidental. These opinions are of far-reaching importance to practice in many ways, some of which I need not point out. But there is a widespread feeling in the profession that many women have been subjected to unnecessarily protracted courses of local treatment not only depleting their pockets, but impairing their delicacy, and even attenuating their morality. If such things are, it may be that a frank recognition of these views would safeguard patients from such meddlesomeness.

One other very important question awaits an answer. What is the pathological explanation of these symptoms? If we say that they are partly neuralgic and partly circulatory, the relation of the two being obscure, perhaps it is the best answer we can at present give, indefinite or insufficient though it may be. It is certain that some of these cases are relieved, and that very speedily, by a combination of ergot with some of the bromides. Other cases seem rather connected with disturbance, especially with insufficiency and concentration of the secretion of the kidneys. It has long appeared to me that such renal disorders are more resented by the female than by the male system. And that in the former, this resentment more often finds expression in the state of the generative organs. I would, at all events, ask you whether you accept or reject the speculative opinions with which I have associated them, to receive these therapeutical hints as at least worthy of being tested in practice. There is one other suggestion to be made in reference to this subject. It is that some, possibly many, of the cases in which no substantial disease can be detected, may nevertheless be outside the category of what we style "functional disorders." It may be that they are really cases of slight and more or less transient inflammation of uterine appendages, including in this term the adjacent peritoneum. An adequate discussion of this most important question would be outside the scope of my lecture. But it is essential to remember that peritonitis is not necessarily attended by rise of temperature. To return now to our more immediate topic. The circumstances of a second example of the radiation of pain were as follows.

A young lady of about eighteen was represented to me, both by her experienced medical attendant and herself, as suffering from excruciating pain in her forehead and temples, nor did her aspect belie this representation. A course of inquiry, similar to that pursued in the former case, elicited a similar sequence of events. The frontal pain had been preceded by pain occupying the vertex and the head on each side of it. That, again, had been preceded by pain towards the back part of the head, which had succeeded to pain in the extreme back of the head and upper part of the neck. Having thus arrived at the original seat of pain, its cause was soon ascertained. It appeared that some months before the patient had occasion to "duck" in order to pass under a transverse beam; coming up too soon, she struck the top of her head with sufficient violence to render her for a short time insensible. It was not for two or three weeks that the pain began in the neck and occiput; and it was not till three or four months after that I saw her. She was suffering from caries of the cervical vertebræ; at all events under treatment based upon this view she ultimately recovered. But the question of diagnosis is of no particular moment as regards my present object. In this, as in the former case, although the attention of the patient was concentrated on each new zone of pain, the previous pains remained; very much as a new baby causes the previous one to sink into comparative oblivion, although it does not efface it. In another somewhat analogous case of occipital headache it required a good deal of perseverance to arrive at the truth. This was that the patient was suffering from fissure of the anus; this being cured, the headache ceased.

The two cases above narrated are, no doubt, exceptional in regard to their intensity and completeness; but these apart, I cannot admit that they are at all exceptional. On the contrary, I think that the same kind of thing is of very ordinary occurrence; and that many incomprehensible pains may, under the guidance of this theory, be traced to their source, and so successfully dealt with. On talking over such cases with medical friends, I have not unfrequently been told that they would call such cases "hysteria." Possibly some of you might do the same. In a certain non-natural sense (to borrow a term from another science), I might, perhaps, do so myself.

You will have foreseen that the introduction of the word "hysteria" was, sooner or later, inevitable, and, perhaps, may give me some credit for having abstained from it so long. Some persons object to the word on account of its derivation. This no doubt embodies an idea, now—and with perfect justice—discarded. No one, probably, at the present moment conserves the notion that hysterical disorders necessarily originate in that anatomical entity known as the uterus. But let us regard the uterus not merely as an anatomical entity, but as a symbol, representing, not simply itself and its appendages, but the sum-total of the peculiarities of the female organisation. The name hysteria, of which, by the way, we cannot rid ourselves, will then serve our purpose without offence. It will embody, not the obsolete conception of a ruder epoch, but one which is in accordance with a wider generalisation from deeper knowledge of the secrets of Nature. It will help to keep present in our minds, as names ought to do, the existence of an extensive series of phenomena, the correlation of these one with another, and their harmony with the reproductive obligations of the female sex. It will suggest also what many insufficiently realise, that when we qualify a disorder or a symptom as "hysterical," we have got not to the end, but rather to the beginning of our clinical investigation. For it is only a first step, though often a very difficult one, to say "this is one of those nervous disorders which are peculiar to women." It still remains for us to discover, if we can, in what particular portion of that immense and complex system the mischief lies. Whether it is intrinsic in or extrinsic to that portion; whether it is due to local or to general causes; whether it is to be met by dietetic, hygienic, moral, or medicinal treatment. If by a combination of these, by which and in what measure of each? Above all, let us remember that these disorders may make life valueless, though they rarely destroy it. And, further, that though difficult to cure, they are rarely incurable if due diligence and sound judgment be brought to bear on them.

(To be concluded.)

THE ALBUMENS OF THE URINE.

BY ROBERT MAGUIRE, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE OUT-PATIENTS AND WARDEN OF THE COLLEGE, ST. MARY'S HOSPITAL.

(Concluded from page 1063.)

IN four cases I have found the urinary albumen to consist entirely of globulin. No serum-albumen, or at most only the faintest trace, which was impossible to estimate, being apparent. Three of these have been to all appearances cases of so-called cyclic albuminuria, and the fourth one of puerperal albuminuria in process of disappearance, and thus resembling the same class of case.

CASE 4.—Mr. B——, whom I saw with Dr. Ransford, had been twice rejected by an insurance company on account of the presence of albumen in his urine. He was somewhat pale and delicate in appearance, of spare habit, and disinclined for exertion. There was no history of scarlatina or diphtheria. The pulse was of quite normal tension, the deep cardiac dulness of normal extent, the cardiac apex-beat in its normal position, and the cardiac sounds and intervals were also of normal duration. He had some slight dyspeptic symptoms, but practically showed no other signs of disease than those found in the urine. This was pale, clear, acid, sp. gr. 1024; it deposited mucus, but no casts or crystals,

Digitized by Google

upon standing. The urine passed before breakfast contained the merest trace of albumen, but later on in the day the amount of albumen was considerable. The amount of albumen was increased by exercise, but not very much influenced by meals. Taking a specimen of urine which contained as large an amount of albumen as possible, I found that this consisted entirely of globulin.

CASE 5.—The patient was a gentleman aged twenty-nine, in whose case I was asked to give an opinion as to the condition of his chest before he presented himself for life insurance. There was a family history of phthisis, and the patient himself was pale and delicate in appearance, though not emaciated. There was no sign of disease anywhere except in the urine, and this contained quite one-fourth of albumen. Now, in the absence of a history of scarlet fever, of dropsy of any kind, of high arterial tension or any cause for amyloid disease, or of any increase in quantity of the urine passed, I suspected this to be a case of functional albuminuria, even though the quantity of albumen was much larger than is usually found in such cases. I asked for two specimens of urine to be sent to me, one passed before and the other one hour after breakfast, and found the former quite free from albumen, the latter containing as much as in the previous examination. The opinion I expressed was that this was probably a case of merely functional albuminuria, and that it was desirable to postpone the proposal for life insurance for at least six months, the patient in the meantime taking tonics and iron. It is now nine months since I saw this case, but Dr. Sworder, of Luton, under whose charge the patient is, has recently forwarded me a specimen of the urine, which now contains much less albumen than it did previously, and this I found to consist entirely of globulin. The patient, in sending the urine, stated that he never felt better in his life than he did at the present time, and he had gained in weight during the last few months.

CASE 6.—A diagnosis of functional albuminuria was made in this case, but the present condition of the patient will be discussed shortly. Mr. S——, a medical student, aged twenty-three, had suffered from repeated attacks of bronchitis as a child, and had had measles, but never scarlatina or diphtheria, nor had he been exposed to the poison of these disorders. A month before consulting me he caught a cold in his head, which, according to his own account, passed to his throat and downwards to the bronchi. He thought his face seemed a little swollen, and said that his hands a little later *felt* swollen, but did not look so, and he was positive there was no œdema. He is of an exceedingly nervous temperament. I at once examined his urine, and found it albuminous. When he consulted me he seemed pale, but not (he told me) more than was habitual to him, and, according to his statement, he felt absolutely nothing wrong with him. He had not lost flesh, he suffered from no dyspepsia, there was no headache, the pulse was of low tension, and there was no extension of the cardiac area of dulness. The specific gravity of the urine was 10·25, it was acid, and contained no casts. That passed before breakfast was perfectly free from albumen; that passed after breakfast, however, gave the mucin reaction which I have to describe later, and contained 0·05 grm. of albumen in 100 cc. of urine. The absence of albumen from the early morning urine was invariable. On four separate occasions I found that the urinary albumen was composed entirely of globulin. If it were not for the history of swelling of the face, this case would at the time have been looked upon as without doubt one of functional albuminuria. The swelling, however, was somewhat doubtful, it lasted for only a short time, and then only while the coryza was in progress, and on deliberation I determined to neglect it. Then, considering the high specific gravity of the urine, the absence of casts, the variability in the appearance of the albumen, the low tension pulse, and the absence of any cardiac enlargement, I made a diagnosis of functional albuminuria. At the same time I recommended great hygienic care and a mixture of arsenic and iron. About one month ago he foolishly went out on a very cold night to attend a midwifery case and caught a chill. Two days afterwards, when I saw him, I found him with a temperature of 101°, and with marked signs of bronchial catarrh. There was no œdema of any kind. The urine, however, was scanty, smoky, and gave abundant evidence of the presence of blood. This lasted for three or four days, when the acute symptoms disappeared and the patient resumed, apparently, his usual health. However, there was now a distinct increase in the tension of the pulse, and the urine contained a larger amount of albumen. On examining the latter, too, I found that it now contained a considerable amount of serum-albumen in addition to the globulin. The present condition of this patient naturally causes one to doubt the diagnosis, made in its earlier stages, of functional abuminuria. Nevertheless, without wishing to force so far-fetched an opinion, I would submit that it is not impossible that the diagnosis formed in the earlier stages might have been correct. It cannot, I think, be too strongly insisted upon that in these cases of so-called physiological albuminu ia we have to do with a pathological condition—a condition which in the majority of cases is recovered from and leaves no trace behind, but which in a certain proportion of the cases results in confirmed kidney disease. There is a weak spot in the body, and that is the kidney. From experimental evidence we know that the passage of foreign albumens through the kidneys will irritate them, and cause the presence of serum-albumen in the urine. So, I believe, in these cases the passage of albumen through the kidneys, even from a functional cause, keeps them in a continual state of irritation, which may in time set up interstitial nephritis, or may render the kidney more liable to the ordinary causes of acute nephritis. The latter, I would submit, is a probable explanation of the hæmaturia in the case I have described, and this view is supported by the change in the constitution of the urinary albumen since the acute attack. Nevertheless, it is also open to consider it a case of Bright's disease from the first, and for scientific verity it should be considered apart.

CASE 7.—This was a case puerperal albuminuria occurring in the practice of my friends Messrs. Crosby and Johnson of Salford, who kindly sent me the urine for analysis. Albumen had appeared in the urine during the later stages of pregnancy; but the pregnancy and labour had terminated without mishap. The urine, which I received a few days after labour, contained 0·1262 grm. of albumen in 100 cc., and this, I found, consisted entirely of globulin. A similar observation made a few days later, when the albumen was much less in amount, gave a like result. This contrasts with the urine of a case under the care of my colleague Mr. Juler, in which after labour the albuminuria persisted, and albuminuric retinitis was present, doubtless from the existence of granular kidney. Here I found a considerable quantity of albumen in the urine, in addition to some globulin; but, unfortunately, I have mislaid the records of the experiment.

To summarise, then, these results. In two cases of granular kidney I found a proportion of 2½ and 4 parts respectively of serum-albumen to 1 part of globulin; in one case of anæmic disorder of the kidney, 1 part of serum-albumen to 2½ parts of globulin; while in two undoubted and one doubtful case of functional or physiological albuminuria, and also in one case of puerperal albuminuria in process of recovery, the urinary albumen consisted entirely of globulin. It may be pointed out that in the above cases the ratio of globulin to serum-albumen was inversely proportional to the gravity of the case, and if the results were to be relied on, an obvious practical import attaches to them. Nevertheless, it is manifestly impossible to draw any conclusion or make any generalisation from so few and, I must confess, such imperfect observations. I am still working at the subject, endeavouring to collect a large number of results from cases of various kinds, and determining the albumen and globulin by a more accurate method.

Dr. Hughlings Jackson has asked me to give an explanation of the occurrence of albuminuria in some cases of exophthalmic goitre, as described by the late Dr. Begbie, and, as such cases are allied to those of functional albuminuria under consideration, it is convenient to discuss them here. The albuminuria in such cases is exactly comparable to that produced by puncture of the floor of the fourth ventricle, or by section of the nerves round the renal artery. In all we have a paralysis of the vaso-motor nerves of the kidney, and hence the albuminuria is due to a vascular lesion. This, however, is not an explanation of how the albumen comes to escape through the vessel wall. Opinions still differ as to the reason why no albumen appears in the urine under ordinary circumstances; but amongst physiologists, at any rate, more stress is now laid upon the functions of that thin layer of epithelium which covers the glomerular tuft—the glomerular epithelium proper as distinct from the capsular epithelium—than was formerly the case. It is this epithelium which secretes the water and salts

Digitized by Google

of the urine, and has probably for one of its functions that of preventing albumen passing into the renal tubes.[1] If this membrane be grossly injured—as, for instance, by the administration of cantharides,—then it ceases to restrain the albumen, and this appears in the urine. But it is not necessary that the lesion should be a gross one; a mere disturbance of nutrition will suffice to disorder the functions of these cells. Thus, the clamping of the renal artery for half an hour will cause albuminuria on the return of the circulation. Now, when the vaso-motor nerves of the kidneys are injured, there is, in all probability, delay in the passage of blood through the glomerulus, and the glomerular epithelium, being insufficiently nourished, ceases to retain the albumens of the blood-serum. This, too, is one of the explanations given for the functional albuminurias which have been mentioned above, and which go by so many different names. It is conceivable, too, that a membrane slightly injured—as, for instance, by such a nutritive disorder as that described, would be unable to retain the highly diffusible globulin, while it might still have the power of keeping back the less diffusible serum-albumen. Saundby and Estelle, to whose observations, as I have described, some little objection attaches, each found two cases in which the urinary albumen consisted entirely of globulin; the diagnosis in these cases were respectively phthisis, physiological albuminuria, locomotor ataxy, and generalised atheroma of vessels, although in the latter there was found, post mortem, a kidney containing cysts.

In a clinical lecture delivered recently at St. Mary's Hospital, I divided cases of functional or cyclic albuminuria into three classes. First, those accompanied by general languor, low tension pulse, and no deposit of uric acid in the urine; secondly, those in which there was robust health, a high-tension pulse, frequently some dyspepsia, and a copious deposit of uric acid in the urine; and, thirdly, those rare cases in which there was some abnormal albumen in the urine. It was, however, pointed out in the lecture that these were rather groups which did exist than parts of a complete classification. Cases do occur in which paleness &c. are accompanied by a high-tension pulse. Now, the cases of functional albuminuria I have mentioned in this paper all belonged to the first group, and, I find, that in a recent paper van Noorden of Giessen[2] has noticed in similar cases an excess, as he states it, of a body having a globulin character, although he gives no further details as to its reaction or the method adopted for its demonstration. I may add, briefly, one case belonging, apparently, to the second group mentioned, as in it the urinary albumen differed from that of the first group.

CASE 8.—Mr. W——, aged thirty-eight, some little time before I saw him, suffered from slight headache, but was at the time of examination apparently in perfect health. Nevertheless, the pulse was of very high tension, and I thought there was some enlargement of the cardiac area, but this was doubtful. There was no history of gout, or of recent exposure to scarlatina or diphtheria. Twenty years before, the patient had had scarlatina, but had recovered without any bad effects. The urine was very acid; specific gravity 1030, deposited a very copious sediment of uric acid and a few hyaline casts on standing, and contained quite one-third albumen. I found that this consisted of 0·22 grm. of serum-albumen, and 0·0406 grm. of globulin in 100 cc. of urine, or a proportion of about 5½ parts of albumen to 1 part of globulin. After treatment for some little time with large doses of carbonate of potash, the deposit of uric acid in the urine disappeared, and with it the albumen become much diminished in amount.

There is another form of true albumen which may appear in the urine. It has been known for some time[3] that a diet of eggs will produce albuminuria, but unquestionably this is difficult to effect. Brown-Séquard[4] produced albuminuria in himself by subsisting entirely upon eggs for nine days, but in doing so he rendered himself seriously ill. The albuminuria so caused is, moreover, not egg-albuminuria. Egg-albumen differs from serum-albumen in its chemical reactions; when precipitated by nitric acid it is not re-dissolved by excess of the acid like serum-albumen, and it is coagulated by ether, while serum-albumen is not.[5] Now, if eggs are taken into the stomach in the cooked form, they cannot possibly enter the circulation until they are transformed into peptones when of course they lose all the characters of egg-albumen. Any albuminuria, therefore, produced by a diet of cooked eggs must be an ordinary albuminuria, and be produced either by a concomitant dyspepsia or by the overloading of the blood with nitrogenous matters, which during their excretion by the kidneys irritate those organs, and so cause the albuminuria. If a diet of eggs is to cause egg-albuminuria, they must be taken in the uncooked state, and even then it is difficult to produce albuminuria. Bernard[6] found albumen in his urine after eating six raw eggs while fasting. Dr. Lauder Brunton informs me that he swallowed six raw eggs without producing albuminuria, but Dr. D'Arcy Power managed to consume more and did produce a slight temporary albuminuria. None of these observers, however, ascertained whether the urinary albumen was egg- or serum-albumen. Stockvis[7] failed to produce albuminuria either in himself or others by the ingestion of from eight to ten raw eggs. I myself a few days ago, after fasting for fourteen hours, swallowed the whites of twelve uncooked eggs, and then fasted for another four hours. One would suppose that under these conditions the egg-albumen would have a fair chance of entering the circulation and appearing in the urine. In my own case, beyond a slight headache, no effect was produced. Stockvis fed rabbits and dogs on raw egg albumen for from three to seven days, and so produced albuminuria. But it does not appear that in this set of experiments Stockvis ascertained whether the albumen in the urine was really egg-albumen or not; moreover, the albuminuria was accompanied by diarrhœa and by the presence of bile-pigment in the urine, and the albuminuria lasted in rabbits for three or four days after the last ingestion of albumen. Thus, the albuminuria may well have been due to the digestive disturbance or to the excessively nitrogenous diet, as in that produced by cooked eggs. On the other hand, if egg-albumen be injected into the veins or beneath the skin of an animal albumen appears at once in the urine, and this Stockvis[8] found to be true albumen. It is evident, then, from what appears above, that the interest attaching to the occurrence of egg-albumen in the urine is purely experimental, and that this substance has at present no place in natural pathology.

Hemi-albumose, a product of the peptic digestion of albumen, is occasionally found in the urine in various morbid conditions. It is precipitated by nitric acid, but on heating dissolves in the acid, giving a bright-yellow solution. When the urine is heated, at first a cloudiness appears, which clears up as further heat is applied; but the precipitate reappears on cooling. It is precipitated by acetic acid, ferrocyanide of potassium, and by various other albumen reagents. Hence, it resembles the albumens on the one hand and the peptones on the other. On standing, it is transformed into peptone. It has been found by Bence Jones[9], Kühne[10], Langendorff and Mommsen[11], in cases of osteomalacia; by Lassar[12] after annointing a dog with petroleum. Dr. Gowers[13] found it once in the urine of a patient who had formerly suffered from glycosuria; and Von Jaksch[14] has seen it in a case of phthisis. Senator[15] denies that its occurrence is so rare, and describes seven cases of various kinds in which he discovered this body in the urine; a similar opinion is given by Huppert.[16] Experimentally, Stokvis[17] found it in the urine when injected into the rectum; while, on the other hand, v. Noorden[18] obtained an opposite result; and when he injected it under the skin of a dog, in only one experiment did a trace of hemi-albumose appear in the urine, although in three experiments albumen was found.

I have several times had urines brought to me which gave a precipitate with nitric acid, but not with heat, and were hence believed to contain this body; but I have always found that the boiling had been performed in a dirty test-tube to which some nitric acid had clung, and this prevented the precipitation of an ordinary albumen by heat. Nevertheless, I have sometimes, in an albuminous urine which has stood for a little time, obtained a precipitate with nitric acid, after filtering off while hot all the albumen which

could be precipitated by boiling, even when great care had been taken to prevent a too great acidity of the urine. I suspect that in some cases a small amount of hemi-albumose may result from digestion of albumen in the urine after it has left the kidneys; for we know that the urine ordinarily contains some pepsine which could easily act on the albumen when in an acid solution. Gehrig[19] has recently made use of this digestive power of urine to determine the amount of proteolytic ferment contained in it. In this connexion, too, there may be mentioned a case reported by Ter. Grigoriantz,[20] in which hemi-albumose was found—seldom, however, alone, but usually with either albumen or peptone. He also found that on standing the hemi-albumose changed into peptone, and after a time it ceased to appear at all in the urine, its place being taken by peptone. In many cases he discovered hemi-albumose, but nearly always with albumen or peptone.

Peptones, on the other hand, are present in the urine with comparative frequency. They are not coagulated by heat or by nitric acid, and they may be detected by precipitating all the albumens by heat and filtering; then peptones may be precipitated in the clear filtrate by picric acid or the brine test. A more reliable and accurate method is that of Hofmeister.[21] The urine is boiled with a few drops of solution of acetate of lead to remove all other albuminous matters; and to the filtrate from these one-fifth of its volume of acetic acid is added, and a small quantity of sodium phospho-tungstate; the peptones are by this precipitated from the solution, and their presence can be further demonstrated by the biuret reaction. The clinical conditions under which peptones are found in the urine are as yet uncertain, and as I have no observations of my own to give they need not detain us long. It will suffice to say that they may be arranged into three groups. The first group comprises those cases in which peptone in the urine is associated with the breaking down of collections of pus in the body, and this may be styled the pyogenic form. The second group contains a few cases which have been described, in which the peptonuria has apparently resulted from profound blood change, and this may be called the hæmatogenic form. In the third group we have definite lesions of the alimentary tract. Now, it is asserted by some physiologists that the peptone formed in the intestine is transformed into soluble albumen in the intestinal wall, and Maixner[22] believes that by disorder of this function peptonuria may result. He thus would explain the peptonuria which accompanies enteric fever and some cases of carcinoma of the stomach, and suggests that this should be styled the enterogenic form.

There is only one more albuminous body which I have to mention, and this—mucin—is important only in so far as it may be confounded with albumen by the ordinary methods of testing. It is precipitated by the addition of acetic acid or citric acid to the urine, and the precipitate is not removed by heat; indeed, there is some probability that one form of mucin may be precipitated by heat, and then is very liable to be confused with albumen. It may also be detected by adding nitric acid to the urine by the contact method. A rim of albumen is seen just at the junction of the acid with the urine. A deposit of urates may occur at the top of the urine, but at about the middle of the column a dim rim is often seen, which is believed to be significant of mucin.[23] The mucin may be rendered still more evident by employing the magnesium nitric test. If the test-solution is poured into the tube first, the mucin comes down very close to the albumen, but it may be distinguished from it by its greater haziness, and by the ease with which it is dispersed by a slight shake. If the test solution is allowed to trickle through the urine, the mucin ring comes down much higher in the tube.[24] At present no significance can be attached to the reaction.

[24] It is not yet certain, however, that this reaction is really due to the presence of mucin. I have never yet found it without albumen being present, and I have seen it in urines which gave no mucin reaction with acetic acid or citric acid alone.

CASE OF REVOLVER WOUND; COMPLETE PERFORATION OF THE STOMACH, WITH RECOVERY.

BY A. H. CLEMOW, M.B.,
LATE SENIOR RESIDENT MEDICAL OFFICER TO THE ROYAL FREE HOSPITAL.

A. H——, a Frenchman, aged twenty-seven years, was admitted into the Royal Free Hospital, under the care of Mr. Boyce Barrow, about 11.30 P.M., on the 24th June, 1885. He was suffering from the effects of a bullet wound (suicidal), whose point of entrance through the skin was marked by a small circular wound, with charred edges, situated about two inches below the left nipple, and a little to the outside of the nipple line. The patient, who was a stout, healthy-looking man, appeared to be suffering from considerable mental depression, and only expressed regret that his attempt had not proved more successful.

Mr. Barrow, the assistant-surgeon, having been sent for, the patient was anæsthetised, and the track of the bullet sought. This was attended at first with some difficulty, but after the external wound had been enlarged, the course of the bullet was traced by the discolouration of the tissues directly downwards for about an inch and a half beneath the skin and through the subcutaneous tissue. Now it was found that the bullet had passed directly between the costal cartilages (corresponding probably to the sixth and seventh ribs), and a probe being passed through the opening and backwards towards the spine in the direction which it was natural to suppose the projectile had taken without encountering anything, it was thought advisable to abandon all further attempts to recover the bullet. The patient was therefore removed to bed, the wound having been freely dusted with iodoform and covered with wet boracic lint. After recovering from the anæsthetic, the patient became very restless, throwing himself about, and crying. A quarter of a grain of morphia was administered hypodermically, shortly after which he slept for an hour. About 2 A.M. there was some coffee-ground vomiting, followed by frequent retching, which continued at intervals throughout the morning of the 25th, the vomiting being repeated at noon. During the afternoon a purgative enema was administered, which, being returned without result, was repeated in the evening, the desired effect, however, not being produced. Twenty minims of the tincture of opium were given at 10 A.M. and 5 P.M., and ten minims at 10 P.M. The patient now seemed to experience a good deal of pain over the lower part of the chest and in the epigastric region. Pulse 100; temperature 99·2°.

June 26th: The patient has passed a very restless night, sleeping but little. The tincture of opium (ten minims) was repeated at 8 A.M. There is some tympanites, and very considerable tenderness over the abdomen, while the pain over the lower part of the chest has increased. A distinct friction rub can be heard to the left of the wound. He was ordered ten minims of tincture of opium every four hours, and poultices over the lower part of the chest and abdomen. Pulse 106; temperature from 99·2° to 100°.—27th: At 9 P.M. last night he took ten minims of antimonial wine in addition to the opium, the two drugs being repeated at 1, 4, and 7 A.M. As, however, vomiting now recurred and was rather troublesome, the antimony was stopped, and three-grain dose of oxalate of cerium administered with each dose of opium. This alteration was followed by diminution of the vomiting, though it did not entirely cease. The vomited matter consisted of a dark greenish fluid, which might have been altered blood mixed with the gastric secretions. Since admission the patient has been allowed nothing by the mouth with the exception of small lumps of ice to suck. To-day nutrient enemata has been administered, each composed of one egg, one ounce of brandy, and four ounces of strong beef-tea, repeated every four hours. As these now seemed to cause a little irritation, the beef-tea was diminished to three ounces and one drachm of the liquor pancreations (Benger), with ten minims of tincture of opium added, the opium by the mouth being diminished to five-minim doses. There having been no action of the bowels since admission, another copious enema was ordered, with the result of a very satisfactory evacuation, the bowels being moved again naturally during the course of the evening.—28th: Patient

Digitized by Google

again passed a restless night, and to-day appears much the same as yesterday. Vomiting of the same character continues and is very troublesome, but the pain is considerably less, and the friction sound has disappeared. He complains much of thirst, and is very restless. Pulse full, 112, and of good tension. Temperature subnormal, 97° to 97·8°. Ordered a small mustard poultice over the epigastrium and linseed poultices over the abdomen, which gave much relief; to be continued.—29th: The patient passed a better night. As he was very restless during the earlier part of the night, the vomiting also being persistent, he was allowed occasional doses of one drachm of brandy in a little soda-water. This was repeated four times during the course of the night, and one dose only was returned, the vomiting becoming much less frequent and ceasing entirely at 6 o'clock. The tongue, which has kept a good appearance throughout, is a little drier this morning and somewhat brown in the centre. Pulse 114, and of good tension. Complains much of thirst, but the pain is considerably diminished. At 10 A.M. he was ordered a drachm each of brandy, of milk, and of Brand's essence; the brandy every alternate hour, and the other two alternating with it. At 1.30 P.M. he vomited about five ounces of bright blood, partially clotted. All feeding by stomach was at once stopped. In the afternoon the vomiting was repeated in smaller quantities two or three times, and in the evening he was ordered a powder containing twelve grains of the subnitrate of bismuth with a sixth of a grain of muriate of morphia, one grain of ergotine being at the same time injected subcutaneously. About 11.30 P.M., more blood having been vomited, the hypodermic injection of ergotine was repeated.—30th: The patient seems much better this morning, and expresses himself as feeling so. He was much quieter during the night, and had two hours' good sleep. Since the last hypodermic injection there has been no vomiting. Pulse 123, regular, and of fair tension: temperature 98°. This afternoon, about 1 o'clock, he vomited a tablespoonful of bright-red blood. The grain of ergotine was at once repeated, but there was a slight recurrence of the hæmorrhage shortly afterwards. The ergotine was therefore administered again at 3 and 7 P.M. At 10 P.M. there was a free action of the bowels, the motion consisting chiefly of very dark blood. During the day the bismuth and morphia powders were repeated every four hours.

July 1st.—At 1.30 A.M., after another motion composed of dark blood, the ergotine injection was repeated. Twice afterwards during the night the bowels were moved, the motions each time being of the same character and smelling intensely fetid. In the early morning he slept about two hours and a half. The vomiting ceased after 3 o'clock yesterday afternoon, and has not returned. He appears very much better this morning, and says he is in no pain. Another very dark motion having been passed at 2 o'clock, the ergotine was again injected. The enemata which have been administered every four hours were now supplemented by the addition of a peptone suppository.—2nd: Slept two hours during the night. The bowels were moved three times, each stool containing blood. Two-thirds of a grain of ergotine were administered at 12 o'clock. During the past twenty-four hours he has been allowed two bottles of soda-water, which he has retained and seemed to enjoy.—3rd: Passed a very good night, and seems much better this morning. Bowels were moved once, but there was no hæmorrhage, neither has he had any pain or vomiting. Allowed Brand's essence in small quantities by the mouth, in addition to the soda-water. Enemata and suppositories continued as before. During the day was more quiet and contented than since admission. Temperature normal; pulse 108.—4th: After another very good night the patient appears much better this morning. Bowels moved once, with no blood. Ordered a drachm of brandy by the mouth every hour, in addition to the Brand's essence and soda-water. Poultices to the abdomen were to-day discontinued, and the wound, which has a perfectly healthy appearance, was dressed with iodoform and boracic lint. Temperature has risen a little this evening (100·6°).—5th: Does not seem so well to-day; was rather more restless during the night. Temperature at 1 A.M. 99°, and at 6 P.M. 102·2°. As there was some abdominal pain, poultices were ordered to be reapplied. There is, however, no tympanites, and he bears palpation well. He looks more pinched and blanched than he did, but there [illegible] any-[illegible]—6th: Very [illegible] very [illegible] this morning. [illegible] given [illegible] mouth.

Feeding by the mouth and by enemata as before. Bowels moved at 2 P.M., the motion being natural. Temperature risen from 101·4° to 102°; pulse 130, tense and full.—7th: The patient passed a much better night, sleeping well. At 6 P.M. he had thirty minims of solution of muriate of morphia, as he was very restless and seemed to bein much pain. The bowels were moved three times during the night, without any sign of hæmorrhage. Pulse 130, but less bounding; temperature 100·6°. The abdominal pain has disappeared, and he merely complains of a little pain around the wound, which, however, has a perfectly healthy appearance.—8th: The patient again passed a good night. The bowels were moved three times, the motions being formed, and containing no blood, pus, or foreign element. As he has now no pain whatever, he was allowed a few mouthfuls of a boiled sole for dinner to-day. Morphia continued in seven-minim doses every four hours.—9th: Passed another good night. Bowels moved at 12.15 and again at 4 A.M., each stool containing a considerable quantity of blood. After each motion a hypodermic injection of one grain of ergotine was administered. A third stool at 9 o'clock contained very little blood. All food by mouth except Brand's essence and soda-water stopped. Bismuth and morphia powders every four hours as before. Temperature varying from 99·4° to 101·6°.—10th: Patient slept from 12 till 4 without waking, and seems much brighter to-day, complaining only of hunger. Bowels were moved once during the night and twice this morning, the motions containing no blood, but smelling very offensive. He looks very anæmic and has emaciated considerably. Allowed a little custard for dinner to-day.—11th: After another good night, patient again looks better. Bowels moved at 6.30 and 10 this morning, each stool containing a small quantity of blood. One grain of ergotine was administered hypodermically at 7 A.M. As the enemata now seemed to irritate him, and he offered considerable resistance to their administrations, they were diminished to three within the twenty-four hours. The bismuth and morphia powders were reduced to one every six hours. Custard for dinner repeated.—13th: Does not seem quite so well to-day. Temperature yesterday afternoon, 102·6°. Since early yesterday morning his bowels have been moved three times, but there has been no return of the hæmorrhage. He complains somewhat of pain in the back, and yesterday it was discovered that gentle pressure in the lower dorsal region a little to the left of the vertebral column elicited pain. To-day there appears to be an indistinct sense of deep-seated fluctuation at this part. The poultices to the abdomen have now been discontinued.—15th: The patient seems much better in himself and is in no pain, though a slight fulness in the back is now perceptible. Temperature fluctuates between 98·4° and 102·4°; pulse 122. All enemata have to-day been stopped, and he was again allowed some sole for dinner.—20th: He now sleeps very well at night and has no pain. Bowels not moved since the 17th. He eats well and is now given a little chicken for dinner. Tongue clean and healthy-looking. Temperature coming down, varying from 98·4° to 100°.

The patient made uninterrupted progress. The fulness in the back had almost entirely disappeared, and there seemed to be no pain on pressure. He was allowed to get up on Aug. 5th for the first time. The temperature had gradually steadied down and had become normal. He was getting stronger every day. Had no pain or discomfort anywhere, and ate, drank, and slept well. On the 14th he left the hospital apparently perfectly well. He was seen again on Aug. 28th; and, though not much stouter, doubtless owing to certain formalities connected with Bow-street through which he had had to pass, told me he was perfectly free from pain or discomfort and felt quite well.

Remarks.—The foregoing case presents many points of extreme interest. That the projectile had passed completely through the stomach there can, I think, scarcely be any doubt. As evidence of this the following points are almost conclusive:—1. There was coffee-ground vomiting within three hours of the infliction of the wound, and this again was repeated a few hours afterwards. 2. There was evidence of localised peritonitis as well as pleurisy, as shown by the tympanites, epigastric pain, and slight rise of temperature within thirty hours of admission. 3. On the ninth day after admission (June 29th), after the administration for the first time of nourishment by the mouth, bright blood was vomited, showing a fresh hæmorrhage from the gastric vessels. Much blood also evidently passed from the [illegible] into the intestine, as shown by the [illegible]

Digitized by Google

of blood, very dark in colour and considerable in quantity, in the motions. This hæmorrhage continued more or less for two or three days. 4. On July 9th, fifteen days after admission, blood again appeared in the stools, giving evidence of secondary hæmorrhage. 5. On July 12th some fulness in the back was noticed over the situation in which the projectile was presumably lying—i.e., on a level posteriorly with the point of entrance anteriorly. This was evidently an indication of the irritation to which the foreign body was there giving rise. The course taken by the projectile must have been somewhat as follows: The point of entrance being between the sixth and seventh ribs, about the junction of the cartilages with the bones, it must have traversed the thoracic cavity just above the attachment of the diaphragm anteriorly. The lung probably escaped being wounded altogether, as there were no symptoms pointing to its injury. The pericardium was also not touched, as at no time were there any symptoms of pericarditis or interference with the heart's action. The diaphragm must then have been perforated, and the bullet have passed completely through the stomach and lodged somewhere in the back, presumably posterior to the parietal peritoneum. The dorsal position which the patient was made to assume throughout would favour the foreign body becoming embedded in the extra-peritoneal tissue, and subsequently becoming encysted.

The patient's recovery is, I think, attributable to the rest given to the stomach in the first instance, allowing the wounds in its walls to become closed in by adhesion, secondary to the peritonitis which ensued. It was to secure this end that opium was at first administered. The vomiting which occurred was evidently due to the trickling of blood into the stomach, as was shown by its becoming allayed as soon as the hæmorrhage was arrested by the ergotine and other means employed. The bismuth was administered with the morphia for a twofold purpose, firstly, as a local styptic, and secondly, with a view to forming a protecting layer over the wounded mucous membrane. It would have been desirable to have withheld all nutriment by the mouth for a longer period than was done in this case. The patient, however, was the most troublesome and restless one imaginable, and it was considered advisable to give way to him to some degree, and in so far as was consistent with his safety, in order to quiet him. The weapon used was a small six-chambered pocket revolver.

Lynton.

PNEUMONIA FOLLOWED BY ABSCESS OF LUNG, TREATED BY TAPPING AND DRAINAGE; DEATH.

BY J. O. BROOKHOUSE, M.D., M.R.C.P.,
PHYSICIAN TO THE GENERAL HOSPITAL, NOTTINGHAM.

J. L——, aged thirty-six, labourer, was admitted on Feb. 11th, 1886. About three months before admission into the Nottingham General Hospital he was attacked with shivering and pain in the left side, cough, and shortness of breath. He was laid up in bed for three weeks, and spat up reddish sputum "like blood." He has never been well since, but made a feeble recovery, and tried to work, but could not. The pain in the side returned, with cough and dyspnœa. Six weeks before admission he noticed that the sputum smelt badly.

On admission, the patient complained of cough and shortness of breath. The cough came on in violent paroxysms, and he expectorated a dark-coloured purulent fluid, having a horrible and indescribable fetor, so as to pervade not only the ward in which he lay but also the neighbouring parts of the hospital. Physical examination of the chest revealed a large cavity at the base of the left lung, with liquid contents. The upper lobe was free from disease. Treatment in the first instance consisted in the use of terebene as an inhalant, and the oil of santal wood internally. No relief or improvement, however, in any way resulted from these remedies, nor was the fetor in any degree lessened. It was decided therefore to tap and drain the lung cavity, and the operation was performed, at 8 P.M., on February 19th, by Mr. A. R. Anderson, by thrusting a large trocar between the seventh and eighth ribs, about an inch to the inner side of the inferior angle of the scapula. Violent explosion of air followed the withdrawal of the trocar with about three drachms of horribly fetid pus. A large rubber drainage-tube was passed through the cannula into the lung, and three ounces of 1 in 80 carbolic lotion injected with a syringe. Considerable coughing followed, and a large quantity of offensive purulent fluid was immediately brought up, but no fluid returned through the tube. The tube was fastened to the skin by a horsehair stitch, and cotton-wool with bandage applied round the chest. Pulse 108; temperature 102·4°; respiration 34.—20th: Has not slept at all; coughed very much through the night; taken food fairly well—milk and eggs; ordered six ounces of wine. Pulse 112; temperature 100°; respiration 34. Dressed this morning; cavity syringed out through the tube with one drachm of Condy's solution to a pint of tepid water, the whole being thrown in gradually; violent coughing accompanied the procedure, during which some passed back through the tube, but five-sixths were brought up by the mouth. The fluid was completely decolourised, being dirty brown and smelling horribly; towards the end of the injection the fluid coughed up became much less offensive.—21st: Has passed a good night and seems generally relieved. Dressed as before; Condy lotion of the same strength to the amount of nearly two pints injected. Five-sixths, as on the previous occasion, returned by the mouth, accompanied with violent cough, but the returned fluid is much less offensive; a small quantity only came back through the tube. Says he gets great relief from the syringing, and from an inhalation of terebene, which he uses four times a day. Has had diarrhœa, the motions being exceedingly offensive; but the bowel looseness is now passing off. Pulse 100; temperature 101°; respiration 28.—22nd: Has passed a bad night; very little sleep, cough being troublesome. Removed during the afternoon to a separate ward in the fever house. Syringed and dressed the same as before. The coughing continued for about two hours after dressing, but considerable relief followed inhalation of terebene. Pulse 104; temperature 99·2°; respiration 28.—23rd: Has passed a fairly good night, and taken food well. Cough not so troublesome, and has expectorated only about two drachms of muco-pus during the night. Dressed this morning, and the cavity syringed out with a pint of the Condy lotion; nearly all returned by the mouth, and a large quantity of purulent fluid, but much less offensive. Coughed violently during the operation and for an hour after, but says he afterwards experiences great relief. During the afternoon slept quietly for two hours, after which he shivered for nearly twenty minutes, but there was no attendant rise of temperature. Bowels freely moved twice, stools semi-solid and very offensive; kidneys are acting well. Pulse 104; temperature 100·8°; respiration 36.—24th: Has passed a sleepless night, coughing the whole time; breathing hurried and noisy, with râles; seems weaker. Cavity syringed out with a pint of the Condy lotion; about half returned by the mouth and an eighth by the tube, so that a portion is retained; the fluid returned much less offensive. The man coughed the whole time, although less violently, but urgent dyspnœa continued for about six hours afterwards. Pulse 90; temperature 100°; respiration 32.—25th: Again passed a restless night, chiefly due to dyspnœa; cough less and little expectoration; seems generally weaker, and cyanosis is marked; there is an anxious facial expression. Temperature 97·6°; pulse 106; respiration 48. On examination of the chest, the percussion note over the upper lobe of left lung is more resonant, and râles are universal. The cavernous breathing posteriorly is over a large area, chiefly upwards. On inspiration there is observed a sinking and drawing in of the intercostal spaces on both sides, but chiefly the left. During the night he has had four ounces of brandy and the same quantity of wine, also a pint of milk and an egg. The cavity to-day has not been syringed out, but there is much less fetor from the breath and wound. There has been no cough or expectoration through the day, but the breathing is laboured and gasping; slight delirium during the evening, and perspiration about the head and face. Breathing became more difficult about midnight, and the patient died at 3 A.M., Feb. 26th.

Necropsy, thirteen hours after death.—On opening the thorax, both lungs filled their respective cavities. The right lung was adherent throughout to the chest wall. The upper lobe of the left lung was free from adhesion. The lower lobe was adherent throughout, and so firmly that the lung was torn in removal. A cavity the size of a breakfast-cup occupied the whole of the base of the left lung; the wall was

Digitized by Google

smooth, and the cavity contained no pus; the surrounding lung tissue being almost black and solid. A bronchus of the second dimension communicated by two openings with the cavity. The drainage-tube had passed into the cavity at a spot rather below its centre. The right lung was engorged and œdematous, and on incising its base pus could be pressed out, showing the passage of this fluid from one lung to the other. Heart normal.

Remarks.—This case, although unfortunately fatal, is published not only for its clinical interest, but as a contribution to the literature of a mode of practice unusual in this country, and also in the hope that it may serve as some guide in the treatment of similar cases in the future. In the first place, it may be observed, whilst no untoward symptom occurred from the operative interference, the man experienced marked and early relief from the cleansing and disinfection of the putrid lung cavity. It is true, cough and dyspnœa were both greatly increased on each occasion during the time the washing-out was being done, but the distress was not continued, and a comparatively long period of quiet followed. Again, the risks of sepsis were immediately greatly diminished, and the patient rendered less offensive to himself and others. It will be noted in connexion with this point that at the post-mortem examination pus was found in the right lung, having been carried there mechanically, and it seems reasonable to me to conclude that the pathological condition was, at least in part, due to its presence. The only healthy portion of lung was the left upper lobe, and the man's death appeared immediately due to the implication of the right lung in the pneumonic process, supervening as it did upon pre-existent grave constitutional disturbance. Cases of abscess and gangrene of lung are at all times of the most serious character, but in spite of the fatal issue in the present instance, the bias of my mind, as the result of the method adopted here, is in favour of further investigation and treatment upon similar lines.

Nottingham.

THE MICROBE OF RABIES.

PRELIMINARY NOTICE.

BY G. F. DOWDESWELL, M.A., F.L.S., &c.

IN view of the great interest now taken in this subject in consequence of the brilliant investigations of Pasteur, I think it desirable to take an early opportunity of stating that I have found the microbe which appears clearly to constitute the virus of this disease. It is a micrococcus, not very minute, and of the usual form. It stains, however, with some difficulty; and this accounts for its having hitherto escaped observation. In the cases of dogs which I have as yet examined, its principal seat is evidently the central canal of the spinal cord and medulla oblongata; thence it pervades the other tissues of the central nervous system, occurring (sometimes in vast masses) around the walls of the bloodvessels, and in some cases within the vessels amongst the red blood-corpuscles. In the cortex of the hemispheres I have found it, but in very small numbers, and, so far, only in the perivascular and peri-cellular lymph spaces. In the cerebellum I have not found it at all, neither have I as yet succeeded in finding it in the salivary glands. I shall shortly publish the methods by which it may be stained with certainty. I must, however, state that it does not stain by hæmatoxylin, either with or without a mordant, as asserted by Fol.[1] I have repeated his methods carefully. Neither does it occur within the nerve fibres, as he states; and, lastly, it is fully three times the dimensions which he gives. I may add that it does not occur in the same situation, treated by the same methods, in normal animals. In the one case of a rabid dog, which I had examined to control my previous observations, the tissues were placed in alcohol so shortly after death as to preclude the possibility of the occurrence of septic organisms. In addition to which, all saprophytes, as far as yet observed, stain very readily with the usual aniline dyes, which this microbe does not. I must point out, in justice to the genius of Pasteur, that these observations on the occurrence of the microbe go far to confirm his statement of the seat of the virus; it may further afford a means of diagnosis in any doubtful case.

Preparations of the microbe were shown at the meeting of the Royal Microscopical Society on the 9th inst.

TRAUMATIC TETANUS, TREATED WITH CHLORAL HYDRATE IN CONJUNCTION WITH URETHAN; RECOVERY.

BY WILLIAM THOMAS JACKMAN, M.R.C.S., &c.

THE following brief notes of a case of tetanus which recovered under the influence of the new hypnotic, urethan, in conjunction with chloral hydrate, are of interest as suggesting a new use for this valuable drug.

J. C——, a lad aged fifteen years, came under my care on March 15th, 1886. The patient presented well-marked symptoms of tetanus, which were evidently the result of an injured finger on his right hand. This had been crushed by cogged wheels five weeks previously, and had healed up slowly under simple local treatment. The lockjaw was complete, and the opisthotonus well marked; severe paroxysms of pain were complained of, which were greatly exaggerated at night. The patient had noticed his neck and jaw muscles gradually becoming stiff for the past few days, but attributed this to a chill. Chloral hydrate in 20-grain doses every three hours was ordered. This relieved the paroxysms of pain slightly during the day, but the lockjaw, opisthotonus, and rigidity of the muscles of the legs remained the same, and the pains were just as severe and frequent during the night. Fluid nourishment was administered and the chloral treatment continued until March 25th, when, as no abatement of the symptoms was apparent, after consultation with my partner Mr. T. Simpson, it was decided to discontinue the chloral during the night, and in its place give the patient four grains of urethan every two hours, from 6 P.M. to 6 A.M. The first night of this treatment showed a marked decrease in the severity of the symptoms, and the patient made gradual and uninterrupted progress until April 20th, when his recovery was established. The failure of the chloral hydrate to relieve the severe symptoms during the nights, and the well-marked improvement under the influence of the urethan, seem to point to the latter being likely to prove a very valuable drug in the treatment of tetanus, either prescribed alone or as above in conjunction with chloral hydrate.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. GEORGE'S HOSPITAL.

A CASE OF EXPLORATION OF THE KIDNEY FOR SUSPECTED CALCULUS.

(Under the care of Mr. WARRINGTON HAWARD.)

THE question of operation in cases of suspected renal calculus is one which not unfrequently presents itself to surgeons connected with large hospitals. If the patient, in good health otherwise, has symptoms of the presence of a calculus, which symptoms from their severity prevent him from following his employment, and medical treatment has done no more than to produce temporary alleviation, most surgeons would follow the course adopted in the following case, and explore the kidney. This case is an example of the difficulty sometimes met with in discovering the stone, even when present, its small size preventing its being felt by the finger or struck by the exploring-needle. We have seen more than one instance of this difficulty in finding the stone, and in one case it was only found after the removal of the kidney, this severe measure being justified by the severity of the symptoms occasioned by the presence of this small calculus. For the following account we are indebted to Mr. R. Margerison, late surgical registrar.

Digitized by Google

John S——, aged twenty-four, a healthy-looking man, was admitted on March 11th, 1885, after having been under observation for some time as an out-patient. Three years previously he began to suffer from occasional attacks of pain in the left lumbar region, accompanied by vomiting, retraction of the testicle, and pain shooting down the inner side of the left thigh. The urine was occasionally turbid, and often contained a deposit, which from the description was probably uric acid. Lately these attacks had grown more frequent, occurring at intervals of about a month, and often lasting for six hours. Active exercise had no influence on the pain, and did not cause any apparent difference in the character of the urine. A year before admission his medical man outside had detected blood in the urine.

When admitted, pressure in the left loin caused no pain, and palpation discovered no abnormality there. No pus or blood existed in the urine.

Three weeks after admission he had a severe attack of his old symptoms, vomiting, retraction of the testicle, &c.—in fact, well-marked symptoms of renal calculus; wanting, however, in the presence of hæmaturia. The urine became highly lithatic. Ten days later a similar attack recurred. It was then thought proper to expose and explore the kidney. This was accordingly done by means of a transverse lumbar incision on April 16th. The kidney and its pelvis were carefully examined by the finger, and a long needle was thrust into the kidney substance in as many places as was thought proper. No stone was found, and much natural disappointment was felt. The man made a good recovery and left the hospital on June 3rd. He has since been to report himself on several occasions. In October he came to say that in September, after one of his old attacks of pain, while at stool he felt a peculiar sensation in the urethra, and heard a distinct click as of a stone striking the earthenware vessel. He has been quite well ever since.

MANCHESTER ROYAL INFIRMARY.

RUPTURED FEMORAL ANEURYSM IN HUNTER'S CANAL; LIGATURE OF THE FEMORAL ARTERY; CURE; SUBSEQUENT DEATH FROM HEART DISEASE; NECROPSY; REMARKS.

(Under the care of Mr. WRIGHT.)

THE notes of the following case have been furnished by Dr. W. Thorburn and Mr. G. Barlow.

William S——, aged sixty-three, a labourer, formerly a soldier, was admitted on January 5th, 1886. There was a history of "brain fever" and of "bowel and liver complaint" while serving in India more than twenty years ago, and of "rheumatism in the hip," lasting a few days, two or three years before admission. There was no history of syphilis recorded. The aneurysm was first noticed about six months before admission, but gave no pain or trouble at first; it, however, increased gradually in size and became somewhat painful later on, though it never prevented him from walking about. On Jan. 4th it had reached somewhat the size of a goose's egg, and in the evening of that day he felt something give way with a crack; he fell down, and at once noticed that the swelling was much larger and very painful. He was admitted the following evening.

On admission the man complained of severe pain in the right knee, running up the inner side of the thigh, where there was a large, flat, obviously pulsating swelling, occupying nearly the lower half of the thigh. The aneurysm was firm, except at about its centre, where there was evidently fluid blood. Pulsation was expansile. There was a distinct thrill and a rasping bruit. There was no tenderness. The veins over it were distended. Pressure on the femoral stopped the pulsation, but scarcely lessened the size of the swelling. The calf of the leg and the foot were somewhat swollen, and there was no pulsation to be felt below the aneurysm. Urine: specific gravity 1020, neutral, free from albumen or sugar. The man's arteries everywhere were obviously atheromatous. He had well-marked arcus senilis, early cataract in both eyes, and chronic bronchitis, with profuse expectoration. Pulse 68 and normal. On the morning of the 6th, when Mr. Wright first saw the patient, the aneurysm was said to be considerably larger than on the previous evening. The foot was not cold. Immediate operation was decided upon. The femoral (superficial) artery was ligatured in the usual way, rather above the apex of Scarpa's triangle. As there was little subcutaneous fat, the vessel was very easily secured with a single chromic gut ligature. The coats were not markedly diseased at this spot. The ligature was tied tightly and the wound closed, no drainage-tube being used. Full antiseptic (Listerian) details were carried out, iodoform and wood-wool dressings being applied. The limb was entirely enveloped in soft wool, and surrounded by hot bottles. Though it was not obvious externally, it was found that blood extravasated from the aneurysm had travelled up the sheath of the sartorius as far as the seat of ligature. Pulsation ceased immediately upon tightening the ligature, but the tumour otherwise was but little altered.

The after-history of the case is absolutely uneventful. There was a little dull aching pain at first, but the foot was never cold, and gangrene never even threatened. The highest temperature reached was 99·4°. The cough improved with a stimulating mixture. Sensation in the foot was never impaired. The size of the swelling slowly but steadily diminished, and the wound healed up at once. On Jan. 28th it was noticed that pulsation could be felt in the femoral to within about two inches of the point of the ligature; below this the vessel was felt firm, cord-like, and evidently plugged. On Feb. 9th there was no pulsation in the tibial vessels; the circumference of the thigh was two inches less than it had been four days after the operation, but there was evidently still some fluid blood in the centre of the swelling. The patient was sent to the Convalescent Hospital on Feb. 13th. He remained well, and the swelling had almost disappeared by the beginning of April, at which time he was allowed to get up, and was practically well as far as the limb was concerned, when he was suddenly seized one afternoon with pain in the chest, and died very shortly after.

Necropsy.—An aneurysm of the ascending part of the arch of the aorta of the size of an orange was found; this had not ruptured, but the heart muscle was very flabby and the vessels atheromatous. The femoral vessels and the aneurysm were removed, and an examination showed that the external iliac, common femoral, and profunda arteries were much dilated and atheromatous. About half an inch below the profunda the upper tapering end of an adherent clot was found. Just above its highest point two small uneven branches were given off. Below this the artery was entirely occluded by clot down to the aneurysm. The ligature had disappeared, but its site, about an inch and a half below the profunda, was marked by a dense white line running round the artery and in the clot; the line was about twice the breadth of the ligature. Below the aneurysm the artery was filled with coagulum as far as the popliteal, where it had been divided; this clot was less firmly adherent than that above the aneurysm, and was perforated at the lower end by two minute orifices. The aneurysm was about the size of a small hen's egg, and was filled with firm laminated clot, except at its most superficial part, where there was a cavity containing about a drachm of fluid blood; this was quite shut off from the artery by a thick wall of coagulum. The walls of the aneurysm were thick, white, firm, and well defined; the sac projected from the interior face of the artery, but no distinct orifice could be made out, nor any sign as to where the sac had given way. The muscles around the sac and also the femoral vein were firmly matted to the sac, but elsewhere there was only a faint discolouration and slight toughening of the cellular tissue to mark the previous extravasation. The course of the collateral circulation could not, unfortunately, be made out, as there was no opportunity for injection or dissection. The aneurysm lay in the centre of Hunter's canal.

Remarks by Mr. WRIGHT.—Cases of ruptured femoral aneurysm in Hunter's canal appear to be very rare, and for this and other reasons I have thought this case worth recording. It illustrates well most of the points discussed in Mr. Poland's paper in Guy's Hospital Reports, series 3, vol. vi., which gives probably the best account of ruptured external aneurysm, and to this I must refer. The sensation of bursting was present in only three of Mr. Poland's forty-two cases; here it was distinct. There was no loss of sensation or fall of temperature of the limb below in any case, though this is nearly universal; and yet in this instance the escape of blood was large and fairly rapid; in other ways the case followed pretty much the general rules laid down by Mr. Poland. As to the treatment of the case, the man was in many respects a most unfavourable subject for operation; he was, however, thin, and of placid disposition.

Digitized by Google

Three possible courses were open to us—amputation, ligature, and pressure. The first was rejected on the ground of the good condition of the limb below; the last on the ground that the damaged vessels and the man's bronchitis made him a bad subject for any prolonged treatment. Mr. Poland's paper clearly makes out that immediate ligature gives the best results. The aneurysm was practically perfectly cured, and the man's death was due to the aortic disease and his flabby heart muscle. The preparation is in the museum of Owens College.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Multiple Neuromata.—Pneumonia.

AT the last ordinary meeting of the session of this Society, held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair, Mr. C. L. Hudson, Dr. L. E. Shaw, and Mr. C. J. Symonds were elected Fellows.

Mr. CHAVASSE read a case of Multiple Neuromata. An apparently healthy woman, aged thirty, who had been treated at intervals for four years for supposed enlargement of the glands on the right side of the neck, submitted to removal of the mass on July 24th, 1885. On dissection, the tumour was found to be intimately connected with the cords of the brachial plexus, and during manipulation the pedicle attaching it to the spinal column was torn across. Death took place from spinal meningitis on the seventh day after the operation. At the post-mortem general neuromata were revealed. These enlargements were mostly fusiform, firm, semi-translucent on section, and microscopically were fibromata. The phrenic, the pneumogastric, and the sympathetic nerves were all affected. The tumour removed was connected with the sixth cervical nerve, the trunk of which formed the pedicle. Microscopically, numerous variously shaped nuclei were seen, but the fibrous tissue development was not excessive. From forty-one cases of multiple neuromata already published, deductions were made regarding the age, sex, nerves affected, clinical history, tolerance of operation, and the malignancy of such tumours. The tumour removed, microscopic sections of the same, and of other neuromata, were exhibited; also a life-sized photograph of the spinal cord and its nerves attached.—Mr. HOWARD MARSH supposed that the free hæmorrhage came from vessels in the interior of the spinal column.—Dr. BUZZARD asked whether the tendon reflexes had been investigated; if they were present it would not signify very much, but it might throw some light on their physiology if absent.—Mr. GANT remarked on the absence of clinical symptoms.—Mr. CHAVASSE said that the bleeding occurred when the pedicle of the tumour came away from the spinal cord; the case was thought to be one of enlarged glands and was so operated on; there were no symptoms except some pain down the arm.

Dr. ANGEL MONEY read a paper on some Statistics of Pneumonia, with especial reference to the Relations of Delirium and Temperature. The paper had been drawn up from the records of the past twelve years of the cases of pneumonia occurring in University College Hospital. Table I. showed the age and sex of all the 199 available cases:—139 were males, 60 females; 27 per cent. occurred under the age of ten years, 20 under the age of twenty, 23 under thirty, 13 under forty, 10 under fifty, 4 under sixty, and 1 under seventy. Table II. gave the lung affected, with the sex. The right alone was affected in 96 cases, or a percentage of about 48; Bleuler's percentage for the right lung was 52. The left alone was affected 70 times, or 35 per cent.; Bleuler gave 32 per cent. There was double pneumonia 33 times, or 16 per cent., which agreed with Bleuler. Table III. showed the number of cases, according to age, sex, and site of pneumonia. All the cases were of lobar pneumonia, the majority of simple lobar pneumonia. Seventeen were complicated with some other lesion; 8 of these had delirium. In 182 cases of primary pneumonia delirium was present fifty-six times, or a percentage of 30. Heinze arrived at the conclusion that mere pyrexia had little to do in the production of delirium. The author's investigations pointed in the same direction. But it cannot be lost sight of that prolonged pyrexia and high transitory fever must exercise some direct and indirect deteriorating influence on the grey matter of the brain and spinal cord, and must therefore predispose to delirium and other signs of exhaustion of nervous matter. Of 17 available cases, sometimes (4) the delirium coincided with the greatest rise in temperature, rarely (2) it preceded the acme of fever, and most frequently (11) the delirium came on with the fall of temperature. Heinze drew attention to the much greater frequency of delirium or marked mental change in pneumonia of the upper lobe. Taking additional precautions by employing only those cases in which the pneumonia was limited to the upper lobes, Dr. Money's observations confirm this statement, and he suggested that the influence of a local inflammation on the cervical sympathetic which controlled the calibre of the cephalic and cerebral vessels might possibly have something to say in the matter. Whether the cause of pneumonia had special deliriant properties should probably be answered in the negative; the suggestion that an alkaloid having a deliriant action was developed during the pneumonic process in some cases must remain as a mere notion. Tables IV. and V. gave the number of cases with and without delirium at different temperatures. A comparison of these tables appeared to show that the number of cases with delirium was largest in those in which the highest temperature recorded was 104° and 105°. This contrast was rendered more apparent by the next table, which contrasted nearly equal numbers of cases with and without delirium. The death-rate in the 199 cases was 20 per cent. From an examination of other tables it seemed clear that the presence or absence of delirium exerted no influence on the mortality. Another table showed the age, highest temperature, and number of cases of delirium. From this it appeared that the third decade of life, when the temperature went beyond 104°, seemed to be the most fertile in the production of delirium, but it was pointed out that this age and this degree of fever yielded the largest number of cases of pneumonia.—Dr. WILSON FOX thought that Dr. Money's paper filled a gap in the literature of pneumonia, since it gave the percentage of cases with and without delirium at different temperatures. Heinze had only given the delirious cases. Liebermeister had advocated the treatment of febrile states by cold, for he believed that the degree of delirium was proportional to the temperature, though this appeared to be more than doubtful. It was interesting to note that the bulk of all temperatures in pneumonia ranged about 104°. From a series of cases collected by himself, Dr. Fox said that in 40 per cent. the temperature ranged from 104° to 105°, 23 per cent. exceeded 105°, and 25 per cent. ranged from 103° to 104°, so that 89 per cent. exceeded 103°. Dr. Fox remarked on the occurrence of delirium at temperatures below 103°, and said it was important to recognise that delirium often set in with a falling temperature. It had been shown by Hermann Weber that acute mania sometimes developed during the resolution of pneumonia. Delirium was in many cases a phenomenon of weakness; sometimes the result of direct poisoning. Some individuals were prone to high fever in pneumonia, and Dr. Fox suggested that it was these who were more likely to develop delirium. The therapeutical indications to be gained by a study of the statistics of pneumonia was not the least interesting part of such work; the application of cold to the treatment of pneumonia, on which Jürgenssen had written, was a very important one; the occurrence of delirium, however, it would seem, was no indication for the use of cold, for it was probable that, as statistics showed, the mortality of delirious cases was not greater than the non-delirious ones. Without entering into reasons, Dr. Fox considered that there were very weighty arguments against the wholesale adoption of the cold treatment of pneumonia.—Dr. STURGES considered that unless the temperatures were taken frequently, say at least every four hours, statistics would be utterly useless and misleading. [Dr. MONEY here explained that it was the custom at University College Hospital to take temperatures every four hours at least in cases of acute pneumonia.] It would be highly important if such work as Dr. Money had done threw any light on the prognosis of cases of pneumonia. It was almost impossible to say which was the case that would recover. Delirium occurred in such varied relations with the other phenomena of pneumonia; he had seen hyperpyrexia without delirium; there was no rule as to its occurrence; the character of the patient doubtless largely determined it. In alcoholic pneumonia the temperature varied considerably, and some

Digitized by Google

of these cases looked almost like delirium tremens in their clinical aspect. Those who over-worked or over-strained mentally were very prone to become delirious; the circumstances in which the pneumonia found the patient were determining factors in the etiology of delirium. As to Dr. Money's anatomical explanation, he thought it proved too much. In young children pneumonia of the upper lobe was common, but there was no special incidence of delirium in them as compared with cases of pneumonia of the lower lobe. He thought the statistics threw light on a very dark place in the study of pneumonia. The strong tendency of pneumonia was to end in recovery, and drugs had but little influence in promoting this.—Dr. NORMAN MOORE discussed chiefly the causes of death in pneumonia. He had made statistics of the last twenty-one fatal cases that had occurred at St. Bartholomew's Hospital; in four of these the pneumonia attacked both lungs, and in two there was pleurisy of the other side; two died from septicæmia after parturition; two had parenchymatous nephritis, three interstitial nephritis, and no less than eight well-marked emphysema. He considered that emphysema was the determining cause of death in many cases, and was often overlooked. The state of the unaffected lung ought to be inquired into; its weight taken, if necessary, after inflation, should œdema be present, to ascertain what amount of destruction of elastic tissue and capillaries and lung tissue generally had taken place by the emphysematous process. Another point of importance in relation to prognosis was the amount of exudation, which doubtless varied much in different cases. Generally, when rather more than half a lung was affected, the weight was 45 oz., but he had known the pneumonic lung to weigh from 67 oz. to 77 oz. This amount of exudation might be determined to a large extent by careful physical examination.—Dr. MOXON remarked on the intense investigation and scrutiny that would be required to establish the physical signs to the extent required by Dr. Moore, and considered that the necessary examination might have something to say in the causation of a fatal issue. He could not concur in Dr. Moore's views as regards emphysema. In his experience overwhelming prostration was the chief danger, and patients did not chiefly die in the way that emphysema chiefly killed. Pneumonia was not peculiarly fatal to advanced life. The question of prognosis in an individual case was dependent on factors belonging rather to physiology than anatomy. He congratulated Dr. Money on his valuable paper.—Dr. SQUIRE said that he had been under the impression that high prolonged fever did have an influence in the development of delirium, and asked how it was that the cases with a low temperature in Dr. Money's statistics appeared to show the opposite.—Dr. A. MONEY, in reply, said that his attempted explanation of the frequency with which delirium occurred in pneumonia in the upper lobe was not meant to prove too much, as Dr. Sturges argued; he regarded the explanation as offering a predisposing cause for delirium, not as actually and of necessity causing delirium by itself, else all pneumonias of the apex should present delirium. He agreed with Dr. Sturges on the frequency of apex pneumonia in children, but, in his experience, he could not concur that delirium such as occurred in adults was to be met with in young children. Rather in the latter there was a tendency to paralysis of the speech centres, which were but little developed in young children and easily overthrown—an illustration of the principle of dissolution as propounded by Hughlings Jackson. Other signs of cerebral disturbance no doubt occurred in children, and might be regarded as their delirium; reference was made to these. He was much interested in Dr. Moore's speculations on emphysema, but agreed with the views of Dr. Moxon. Taking the whole of the arguments in his paper, Dr. Squire would find that there was really no issue between them.

THE ARMY MEDICAL STAFF DINNER.—A very pleasant gathering of the medical officers of the army was held last week at the Holborn Restaurant. A large number attended, and Sir Thomas Crawford, K.C.B., was in the chair. After the usual loyal toasts had been given and heartily responded to, "The Health of Sir Thomas Longmore" was proposed by the chairman, who called attention to his long and arduous work. It was drank with great enthusiasm. The President of the College of Surgeons responded for "The Visitors." The *réunion* was exceptionally agreeable.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, JUNE 3RD.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE Council went into committee for the further consideration of the proposals relating to elementary mechanics.

Mr. MACNAMARA said that, though there were some schools in county Dublin at which hydrostatics was taught, those who were acquainted with the geography of the district would know that it would be impossible for students to travel to and from them. Most of the schools which efficiently taught the subjects were Roman Catholic, while the majority of the medical students were Protestants, and the *odium theologicum* was so prevalent in Ireland at the present time that Protestant parents would not send their sons to the Roman Catholic schools. Six Irish gentlemen, representing different places, had told twelve English and six Scotch gentlemen that it was impossible and impracticable to do what was proposed, but in their great superior wisdom the English and Scotch gentlemen said, "Go home, and do that which is impossible." If ever there was a thing in the world that would change his political convictions, which had been strongly against Home Rule, it was this conduct of the Medical Council. (Laughter.)

Dr. HERON WATSON said that Mr. Macnamara's speech apparently meant that the condition of education in Ireland was in a very bad way, and that it was physically impossible for the young men there who wished to study medicine to get to the places where they could be taught. It appeared to him that all the mechanics required could be obtained from text-books, though of course the subjects could be far more thoroughly studied at schools where there were proper appliances. He was extremely grieved to notice that the representatives of the great old English universities were apparently diligently set against the inclusion of so simple and humble an amount of preliminary knowledge in physics as his amendment implied. It would lead the profession at large to imagine that the universities did not wish the students to enter upon those subjects a knowledge of which would render the study of medicine easier.

Dr. BANKS said that the requirements of the University of Dublin were in reality higher than those of the Council, and he did not think it was likely to alter them.

Dr. PETTIGREW said that if the Council affirmed its regulation all difficulties in teaching would soon disappear. The universities, no doubt, had a higher standard than the Council required, but that higher standard ought not to be allowed to stand in the way of the lower standard of the Council.

Dr. QUAIN protested against the interminable discussion on the question of preliminary education, which ought to be left entirely to the educational bodies of the country. The everlasting changes were most perplexing to the students and teachers, and he hoped they would now cease.

Mr. MARSHALL said that the Council had lightened the preliminary curriculum in regard to certain subjects, such as history and geography, in order that physics, which was regarded as more important, might be included; and he hoped that the Council would adhere to its former resolution. If the Council had adopted a motion which he had proposed, giving an intermediate scientific year, the present difficulty would not have arisen; but as that could not be, they were anxious to have a provisional measure. They had to consider a large number of ordinary students, rather than a small number of more highly educated students. Even if, as had been suggested, university students would not register, that would be a less evil than altering the present regulation of the Council.

Dr. HAUGHTON said it was impossible to compel the students of his university to go upon the Register. The university would never have an examination in arts for any particular profession, but would provide such an examination as would be best for all professions. He entirely agreed that students who were not going to take the higher university training in chemistry and natural philosophy should be compelled to show some elementary knowledge of those subjects before entering upon professional practice.

Dr. HERON WATSON asked Dr. Haughton what would

Digitized by Google

become of the mechanics of a student who, after being registered as a medical student at a university without passing in mechanics, gave up his study there and went in for examination at one of the corporations. If he were a registered medical student the corporation would be bound to examine him, and so he might obtain his diploma without any knowledge whatever of elementary mechanics.

Dr. HAUGHTON said he entirely agreed with Dr. Watson as to the desirability of the subjects being studied, and therefore he had not proposed an amendment. This matter had been carefully considered in Dublin, and they wished to have it known that they retired from the Medical Register without any offence. They would not cease to register because they were recalcitrant against the proposals of the Council, but because they would be no parties to a fraud.

Mr. SIMON said that university students had a longer curriculum than four years, but the Council had to think mainly of men who had to do their work in four years, and the Council had put their foot down on the position that if four years were deemed sufficient it was only on the condition that certain kinds of knowledge were first cleared off the ground. He hoped that they would not shilly-shally and make exceptions because of the pleadings of any institutions. Whether Trinity College students registered in the first year or not was absolutely unimportant. Whenever they registered they would be passed in the preliminary subjects. He hoped, therefore, that the Council would see their way to maintain their former resolution unchanged.

Dr. HUMPHRY suggested that perhaps the amendment might be accepted if words were added to the effect that the university examinations would be accepted as heretofore, provided that at that or a subsequent examination the students passed in mechanics.

The amendment was ultimately agreed to in the following form: "That examination in the subject of elementary mechanics of solids and fluids—comprising the elements of statics, dynamics, and hydrostatics—should be required in the preliminary examination, and should be passed before registration in the Students' Register; but in universities with a prolonged curriculum, where the examination in mechanics required for their degree is taken at a more advanced period of study than before commencing medical education, the registration may be effected on having passed the examination in mechanics, and it shall be the duty of the Registrar to antedate the entry to the period at which the preliminary was passed."

Dr. HAUGHTON then moved: "That, in the opinion of the Council, it is highly important to visit and report upon the methods of teaching required by the licensing bodies." He said the good done by visitations of examinations had been of a moral kind. Abused as the Council had been for the little it had done, it had exerted an extraordinary amount of moral influence in improving the standards of examination and education, but he had come to the conclusion that the appliances and means of teaching were far more important than the mere examination. But since Lord Brougham's death the examination hobby had not been ridden so strongly as it was previously. The teachers were more important persons than the examiners, and that was why in Ireland the schools had been asked what machinery they possessed for teaching mechanics. The tendency of enlightened medical education was to reduce the formal lectures, and to increase the means of learning by the eye and by the hand. He disapproved of the Scotch system of requiring the unfortunate student to attend a hundred lectures in a course. A very brilliant man might make such a number of lectures attractive, but the majority of teachers did not do so, and the students might with great advantage be referred to the best text-books for one-half the lectures. There was a system in Dublin of requiring a student to attend, or at least pay for, three courses of lectures on the same subject, and that also needed alteration. If the Council agreed to his proposals, he had reason to believe that the cupboard which would be unlocked would be found to contain a very large number of skeletons. Some very pretentious schools would be seen to be very badly provided with the means of teaching, and it would be discovered that grinders often took the place of the brains, eyes, and hands of the learners. The inspection of the appliances at the schools could be carried out very cheaply by means of the Branch Councils; and, in fact, in Ireland, at present, the College of Surgeons, Trinity College, the Royal University, and College of Physicians had the right to send inspectors to all the schools before they recognised them; and schools had been taken off the list for imperfect means of teaching, and restored upon an improvement taking place. He asked some of the most distinguished visitors to the International Medical Congress what they thought of the medical schools in London, and they said nothing could be more perfect than the facilities for practical instruction for hospital work, but nothing could be more elementary and crude than some of the teaching of anatomy, chemistry, botany, and zoology. The College of Surgeons and the College of Physicians in London had not done their duty in inspecting the schools, and therefore the Council ought to take up the question. No doubt the red-tapeists on the Council, who were not few in number, but were very noisy and persistent, would say that there was no legal power to do what he proposed, but the only power the Council had hitherto exercised had been through moral influence. They had never called upon the Privy Council, and he hoped they never would. Good schools would be glad to be visited, and the bad schools would have to spend money to improve their premises, to get good teachers, and to work up to the level of the other schools. Many of the corporations were very lax as to the attendance on lectures.

Dr. DUNCAN, in seconding the motion, said he cordially supported the abstract resolution, though he did not agree with all the observations made by Dr. Haughton. He would rather have the country supplied with well-educated practitioners who had passed no examination, than with a set of men who had merely passed an examination but showed no length of time in education. The Council had the same power under the Act to interfere in regard to courses of study as in regard to examinations. Besides that, the Council many years ago entered upon a laborious inquiry, over which Mr. Syme presided, as to the courses of study, but for some reason or other the subject was dropped. He was quite sure that Dr. Haughton was wrong about the value of lectures in the Scotch system. As a proof of that, he might mention that all the best students attended most regularly, and when not required to attend they did so voluntarily. If there were any weight in Dr. Haughton's statements, lectures might be wholly given up and the students supplied only with books, laboratories, and practical education. The *vivâ voce* lectures of a good teacher would always be valuable, while a text-book or a written lecture would send a man to sleep. A man would learn midwifery better in three months by attending lectures than in two years from a book. It appeared to him that medical education, especially in England, was upon a wrong footing. A man must spend years to learn the Latin that was required of him, but he might pass in midwifery though his education had been a perfect farce. It was far more important for practitioners to have a high knowledge of medicine and midwifery than of Latin.

Dr. BANKS supported the resolution. The university that he represented had instituted an inspection of the schools whose certificates they received, and he quite agreed that an inquiry into the means of teaching at the schools was of more importance than reporting upon the examinations.

Mr. SIMON said that he entirely shared the sentiment of the resolution, but he did not think that the Council had power under the Act to institute an inspection of the means of teaching, though they had power to require the licensing bodies to inform them on the subject. It had always appeared to him that the Council had only an indirect relation to the schools, and he thought they should, in the first instance at all events, rather address the examining bodies and inquire what steps they took to satisfy themselves as to the means of teaching.

Dr. HAUGHTON said he only wanted the principle affirmed first.

Dr. HERON WATSON supported the motion. While a diploma was a *testamur* that a man had passed a certain form of examination, it would afford no real indication of how the instruction had been communicated to him. It might be said that attendance upon mere lectures was a misfortune, but what could be said of students who had merely gone through a system of cramming six hours a day, as though medicine could be taught by a series of Pinnock's Catechisms? It was most important that in all the schools the authenticated teachers should be persons who gave instruction in a way calculated to improve the thinking faculties of his pupils. In Edinburgh and Glasgow, no man external to the universities was accepted as qualified to lecture unless he proved that he had a proper museum to enable him to fulfil all the demands of the licensing bodies. Lectures in London and Dublin were also accepted,

Digitized by Google

but over those the bodies in Edinburgh had no control whatever, and though he should desiderate for all teachers the widest possible latitude as to what they taught and how they taught, it was a matter of great importance that all the bodies should be well assured that the teaching in all the schools was, if not of a uniform standard, at all events of uniform quality. There were no means by which this result could be obtained except by the Medical Council taking the matter in hand. Allusion had been made to attendance at 100 lectures being required in Edinburgh, but the course included anatomy, physiology, surgery, and medicine. He believed that in some schools there was a great want of regularity on the part of teachers. Let them take the case of a lecturer on operative surgery affixing to the gate of the hospital a notice that at a certain hour on a certain day he would commence his class; the first day he turned up, but for a week after nothing was seen of him, while the corpse was going to corruption and the class was becoming demoralised. He mentioned this simply as one of the rumours current in the air, and it would be a great pity if the Council did not assure themselves whether or not there was any truth in these charges. No doubt it would be said that the student could protect himself, and might leave one school and go to another, but he might waste the whole of the four years in finding the right school.

Dr. QUAIN said he had no faith in lectures, believing that in half the cases it was a perfect waste of time to attend them, and that infinitely better information could be obtained by books and observation. The motion was to the effect that the Council had no confidence in either the examining bodies or the schools, but they had no power whatever to visit the schools. He hoped that they would simply call the attention of the various examining bodies to the necessity of careful supervision of the schools.

Mr. MARSHALL thought that the Council had power to send a visitor to a university to report both on the examination and the course of study, but could not do so at the medical schools. No doubt it would be highly desirable for them to know all about the teaching, but he must repudiate the imputation that there were teachers in London who did not perform their duties, even after they had advertised their lectures. Unless some proof were brought forward, such imputations should not be indulged in. The combined Colleges in London were composed of men who knew all about the character of the schools, and he was quite sure that the Colleges would soon learn if there were any serious defects in the schools. It must be admitted that there was a great difference in regard to the materials for teaching, but the means of the smaller schools must be measured against the requirements made upon them. A great deal might be said in favour of the spirit of the motion, and he saw no harm in passing it as an abstract resolution, trusting that good might come out of it.

Mr. MACNAMARA believed in the value of lectures if they were of an attractive character, but if they consisted merely of reading from a book the student would be very much better elsewhere. He agreed that the Council had no legal power to inspect the schools, but in self-defence no school in London would refuse to admit a gentleman sent by the Council, and a great deal of good would be done if the Branch Councils were requested to institute some inquiries. On the establishment of the Carmichael School, he was not ashamed to say that the College of Surgeons in Ireland found that their facilities for teaching some subjects were not so good as those in the school. The result was that the College improved their means, and he believed that a similar result would be attained in other cases.

Mr. TEALE said that the mere fact of the motion being discussed would be of value even if the Council went no further. He agreed that the Council had not the legal power to do what was sought, but the difficulty would be got over by a courteous request for permission to visit. One good result from such action would be that the members of the Council would be brought into contact with the junior teachers, and the eyes of the Council would be opened to the growing evil that examinations were doing in spoiling study. Teachers had told him that students had no time now for study, their whole time being occupied in working up for examinations.

Dr. HUMPHRY said that ten years ago he brought this subject forward, and he was therefore glad that the proposal was now renewed. The manner in which it had been received on the present occasion showed that there had been an advance in opinion on the subject. Teaching and examinations were complementary to one another. There would not be good effective teaching unless there were good effective examinations, and the examinations should not be regarded simply as tests, but as directions for teaching. Every question set by an examiner should be a guide to the teachers in the several schools. Some teachers undoubtedly taught a great deal by lectures, but others did not; but he thought that the very best mode of repletion in teaching was depletion, and students had asked him if he could not give them a whole course of teaching by examinations. Perhaps the tendency of education at the present day was to run rather too much into practical matters, without sufficiently considering the theory. There was nothing he more desired for his school of medicine than a visitation from the Medical Council, for it would give it a great impulse.

The Council then adjourned.

FRIDAY, JUNE 4TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The debate on Dr. Haughton's motion on the methods of teaching required by the licensing bodies, was resumed by

Dr. STRUTHERS, who said he should support the motion, but did not approve of what had been said about lectures. In Scotland and Germany the word meant demonstration blended with discussion. Medical education depended not only on the materials, but on the use made of them. It was not the carriage but the horse and the driver that were important. In a thorough medical school the fundamental sciences should be taught by men devoted to their special subjects. It would not do to have anatomy, for instance, taught by men in practice, but by those who, like Harrison, Christison, and Syme, stuck to their chairs and gave a character to the school and an inspiration to the students. Teachers should also be examiners. In Scotland the teacher was an *ex officio* examiner. But he had with him an outside examiner. No system of examination could be complete in which the teacher did not take part. If such were not the case it would be impossible to keep up the high tone in the school, and he would rather sell postage stamps in a post-office than be a teacher under those circumstances. The Scotch universities and schools would be delighted to have visitors, and would be happy if other parts of the kingdom copied the system; but there was something else that they should copy—namely, Scotch industry and Scotch contentment, with slight remuneration.

Mr. MACNAMARA.—And Scotch modesty. (Laughter.)

Dr. PETTIGREW maintained that good practical lectures are a valuable means of instruction. He supported the motion, and expressed his belief that if it were carried into effect a good work would be done by the Council.

Dr. HALDANE also supported the motion, but dissented from some of the remarks of Dr. Struthers. He believed that students were very much over-lectured, and he disapproved of the teachers taking part in the examination of their students. As to the moderate incomes of the professors, some of them were receiving salaries of as much as three or four thousand a year.

Dr. HAUGHTON, in reply, expressed his gratification at the amount of support accorded to his motion. He especially thanked his Scotch friends for their support. He had no idea that he should be raising such a storm by his reference to the heaven-inspired, divinely-descended hundred lectures per term. (Laughter.) But he thought that that number of lectures from the very best lecturer who ever lived, even in Scotland, was far too large.

The motion was put and agreed to *nem. con.*

Dr. HAUGHTON then moved: "That visitors be appointed by the General Medical Council to visit the several medical schools (with their permission) in each division of the kingdom, and to report upon their methods of teaching the subjects required by the licensing bodies." The motion, he said, was intended to give effect to the resolution just passed. As to the precise mode to be adopted, that he was willing to defer to the opinion of the Council. He did not think, however, that the proposed visitation should be conducted by the universities or corporations, which would be both unpleasant and invidious. Nor should the Branch Councils alone be entrusted with the work, though he thought they should take part in it. His idea was that each Branch Council should conduct the inquiry in its own division, with the aid of a representative from each of the

Digitized by Google

two other divisions. In that way the moral weight of the visitation would be greatly increased, and all delicacy and difficulty in conducting it would disappear.

Dr. HERON WATSON, in seconding the motion, said he hoped that the visitation would be carried out in a much more economical way than in the case of some of the recent visitations. He had no doubt that members of the Council in Scotland, for example, would undertake a complete inspection in their own division, without reference to cost, but they could hardly expect that a member should attend from England or Ireland without being paid. He thought the best way would be to refer the subject to a committee to consider and report upon the best method of carrying out the visitation.

Dr. A. SMITH supported the motion, but suggested the addition of the word "appliances."

Dr. Haughton and Dr. Heron Watson accepted the suggestion, and permission was granted to add to the resolution the words "and upon the appliances possessed by them for such purposes."

Dr. QUAIN, as the treasurer, said he did not believe the scheme could be carried out for less than 1500 or 2000 guineas. He therefore protested against making regulations which they might not have funds to carry out.

Dr. STRUTHERS also thought the expense would be very serious. A long time would have to be occupied in carrying out the inspection, and it would probably be sufficient at first to apply to the licensing bodies. He would therefore move as an amendment, "That the Council, having had under consideration the subject of visiting and reporting on the methods of teaching, resolves to communicate with the several licensing bodies, and to ask for information as to the means taken by them to secure the best methods of teaching."

Dr. QUAIN seconded the amendment.

Dr. DUNCAN said he regarded it as quite unworthy of the Council to raise the question of expense. They had £33,000, and he did not know what was the use of all that amount.

Dr. QUAIN.—That money belongs to the English Branch Council.

Mr. MARSHALL considered the amendment more acceptable than the motion. If any inspection were carried out, it must be a very prolonged one. The method of electing teachers, their mode of teaching, the regularity or otherwise of their attendance, would all have to be inquired into. A great deal of invidious inquiry would have to be undertaken, and unless it were done thoroughly it would be of no value. The Council had expressed an opinion that at some time or other it would be desirable to visit and report. The very vagueness of the proposition recommended it to him, and even if a committee were appointed to draw up a scheme it would be a long time before the inspection could begin. He therefore thought it would be better in the meantime to apply to the licensing bodies.

Dr. CHAMBERS said that examiners easily ascertained for themselves the value of the teaching of the different schools, but they never made the information public. If the Council asked for information of that kind from the licensing bodies some good might come of it.

Mr. TEALE supported the amendment.

Dr. HAUGHTON said he would never consent to sending back the question to corporations and universities who, with very few exceptions, had never done their duty. That course would be simply evading the responsibility of the Council. Many bodies accepted in the most slovenly manner certificates of lectures and teaching without any inquiry as to their real value. In Ireland, at any rate, he knew that certificates were often granted of lecture and hospital attendances without any guarantee that such attendances had ever been given.

Mr. SIMON, in supporting the amendment, said that the real check on a school was to be found in its own commercial interests. Where there was a proper system of examination, a school that did not properly educate its students would not pay. He wished to refer the Council to a report (in which he had taken some part) made many years ago by the Council of the London Medical Teachers' Association. To the principles embodied in that report he still adhered. He considered that at present the schools were greatly over-regulated.

Dr. PETTIGREW thought that if an intimation were given to the schools that at a certain date the visitations would commence, that note of warning would lead the schools to prepare themselves and make good any deficiencies in teaching or appliances.

Dr. HUMPHRY said he should strongly object to any inquiry into the manner of teaching adopted by individual teachers. He should protest against any visitor attending one of his own lectures with a view to reporting upon it to the Council. He should not object to an inquiry into the general plan of education and the means and appliances, which would be a work of no great difficulty or expense.

Dr. HAUGHTON said that nothing was further from his intention than to suggest an examination of the manner in which individual teachers taught their pupils; his object was to secure an inquiry as to methods and appliances.

Dr. QUAIN considered that a lecture was part of the method adopted, and should therefore be the subject of inquiry. It would be better to get information from the corporation than to appoint visitors at once.

Dr. HALDANE supported the motion as a sequence to the previous resolution.

The amendment was then put and lost, ten voting for it and eleven against it.

The PRESIDENT, before putting the original motion, mentioned that many years ago a committee, presided over by Mr. Syme, drew up an elaborate report on the same subject, but the object of the committee was purely to seek information from the best authorities, and not to criticise. Ever since he became a student of medicine it had been to him a matter of great personal interest to obtain information in the same direction. Until within the last few years, he never went into a town where there was an important hospital without going through that institution in order to learn what were the appliances and arrangements there. One point that he always inquired into was the state of cleanliness. In some places the disorder in the dissecting rooms and the student's rooms was a disgrace to a civilised country. The state of things, however, had immensely improved during the last thirty years. He knew many instances where, from sheer ignorance, the managers of institutions would not provide the necessary funds for proper appliances. It was for the Council to decide whether they thought it desirable to carry out the proposed inquiry in a critical spirit, or simply wished to obtain information from the best sources.

Dr. Haughton's motion was then put, and carried by thirteen against four.

On the motion of Dr. HERON WATSON a committee was appointed "to consider and report upon the best system by which the visitation of the several medical schools, as now determined upon, may be carried out." The committee consisted of Dr. Haughton, Dr. Humphry, Dr. Chambers, Dr. Struthers, and Mr. Marshall.

On the motion of Mr. MARSHALL, seconded by Dr. A. SMITH, it was resolved: "That the Registrar be empowered, under the sanction of the President and the Treasurers, to collect, by purchase or otherwise, the various Acts of Parliament, Parliamentary Reports, and Parliamentary Bills which relate to the medical profession, the similar Acts passed by Colonial Legislatures, the charters, statutes, and bye-laws and regulations of the several universities and medical corporations of the United Kingdom and the colonies, the regulations of the more important foreign universities or other medical authorities, certain selected returns of the Registrar-General, special statistical reports, foreign pharmacopœias or codices, and any other documents or books on subjects connected with the work of the General Medical Council, in relation to medical education, examinations, and qualifications. That the Registrar be further authorised to provide suitable book-cases or other accommodation for the safe custody of the above-named collection or library of reference, and to prepare a suitable catalogue of the same. That the library so formed be available to members of the Council and to such other persons as may receive the permission of the Registrar to make use of it."

Mr. MACNAMARA moved pursuant to notice: "(*a*) That the invested funds of the several Branch Councils should be consolidated into one capital fund, vested in trustees on behalf of the General Medical Council. (*b*) That the local registrars should continue, as at present, to register and receive registration fees in their respective localities, but should, without loss of time, transmit such fees to the medical registrar when they amount to ( ). (*c*) That the treasurers of the General Medical Council should transmit from time to time to the registrar for Scotland or Ireland such sums as may be necessary to defray the current expenses of the local offices. (*d*) That the salaries of the registrars of the Branch Councils for Scotland and Ireland should be paid by the treasurers of the General

Digitized by Google

Medical Council. (*e*) That fees for attendance on Branch Councils should also be paid by the treasurers of the General Council at the end of each current year." He said that the profession generally knew very well about the financial position of the Council. It was generally believed to be a wealthy body, but in truth it was wretchedly poor, having scarcely any funds at its disposal. The income of the General Council in 1883 was only £221 14*s.* 8*d.*, and in 1884 £165 11*s.* 2*d.*; in 1885 it was larger owing to the exceptional receipts from the sale of the new Pharmacopœia. By Clause 13 of the Medical Act all moneys payable to the Branch Councils were to be paid to the treasurers of such Councils respectively, and to be applied to defray the expenses of carrying out the Act. Separate accounts were to be kept of the expenses of the General Council and of the Branch Councils, but the expenses of the General Council were to be defrayed by means of an equal percentage upon all moneys received by the Branch Conncils. A return was to be made by the treasurers of the Branch Councils of all moneys received by them, and the percentage having been computed the contributions were to be paid to the treasurers of the General Council. The expenses of the Branch Councils were to be defrayed by those Councils out of the residue of the moneys so received. The percentage was calculated upon the income of the Branch Councils. It appeared that there was now a sum of £33,000 in Consols standing to the credit of the English Branch Council, of the Scotch Branch Council £3800, and of the Irish Branch Council £1869. What was the meaning of that disparity? Two years ago he went over the Register and found that 3223 names had been recorded on it as having been registered by the English Branch Council in virtue of qualifications obtained exclusively in Scotland or in Ireland. He had also ascertained from the Registrar that during the last year Scotland had suffered in that way to the extent of 120 practitioners and Ireland to the extent of fifty-two, the reason being that the English Branch Council had enriched itself at the expense of the Scotch Branch Council by £600, and at the expense of the Irish Branch Council by £260. At the time he made the investigation he found that there stood to the credit of the English Branch Council £10,000, which of right belonged to Scotland, and £9869 belonging to Ireland. The explanation was simple enough. After the students had completed their education they sought assistantships in England, and as registration was required for that purpose they went to the English Branch Council and paid them £5, which ought to have been given to the Scotch or Irish Branch Council. In 1860 a committee appointed to report on the subject called attention to the fact that by the present arrangement it was possible that so large a proportion of the registration fees might be paid into the fund of any one Branch Council as to leave the others without sufficient funds to carry out the purposes of the Act, and they recommended that all the moneys should be paid into one common fund, from which all the expenses of the General and Branch Councils should be defrayed, subject to the supervision and approval of the General Council. In 1878 another committee was appointed, in consequence of a letter received from Mr. Peel, and upon the recommendations of that committee his present motion was founded. If the Bill now before Parliament became law, the visitations contemplated under it would involve great expense, and the funds of the Irish and Scotch Branch Councils would soon disappear unless some special means were provided in the Bill, and the work would therefore collapse. When they became bankrupt they could not of course contribute the required percentage. Three courses were open to them—to disgorge the money due to Scotland and Ireland (laughter), which was perhaps impracticable; to have a common fund, as proposed in the resolution; or to have an arrangement by which the registration fees of Scotch and Irish practitioners received by the English Branch Council should be sent to the particular division to which the practitioners belonged. If the Council accepted his resolution, he was authorised to state that an amendment would be introduced into Sir L. Playfair's Bill to that effect.

Dr. HERON WATSON seconded the motion.

Mr. SIMON asked if it was proposed that the General Council should regulate the actions of the Branch Councils?

Mr. MACNAMARA said the autonomy of the Branch Councils was preserved intact.

Mr. SIMON said it appeared that the autonomy of expenditure was preserved, but the General Council had no control over the Branch Council. Of course every Englishman would wish to have these things on a perfectly equitable ground, but it would not be right for the Branch Councils to be allowed to dip their hands in the common purse unless the common body had some regulation over them.

Mr. TEALE said the fees received by the Branch Councils might be retained by them; out of that they might pay their expenses, and at the end of the year hand over the balance to the common fund.

Mr. SIMON.—But Mr. Macnamara expects a bankruptcy.

Mr. TEALE said that before there was a percentage rate the current expenses might be paid.

Dr. QUAIN said the £33,000 belonged to the English Branch Council, and the other Branch Councils had no more right to touch that sum than his own private income. Men went to Scotland and Ireland on purpose to pass, but came to England to practise. There was a sufficient explanation why the funds of the Irish Branch Council were very low. In Ireland in 1860 the funds invested amounted to £3120; in 1886 they were only £1870. In Scotland, on the other hand, in 1860 the funds were £2000, and in 1886 £3300. That showed that the Irish had been very extravagant, and no doubt it would be delightful for them to have the English fund to draw upon. What on earth induced them to hold six meetings and spend £76 in considering the Medical Bill? Was that the way in which the funds were to be wasted? If Irishmen would be more economical and induce more of their students to register in Ireland such an application as the present would not have been necessary.

Dr. A. SMITH supported the motion, as he thought the three funds ought to be amalgamated and in the custody of the General Medical Council. The large sum possessed by the English Branch Council arose from the fact that the first annual account showed that their total receipts then were £26,000, while in Ireland they were £4400, and in Scotland £3700.

Dr. HAUGHTON said that if the English representatives thought there was something inequitable in the present condition of things, they would surely help to remedy it, and Mr. Macnamara had told them that Sir Lyon Playfair was prepared to follow up a vote of the Council in favour of the motion by a clause in the Amendment Act.

Dr. QUAIN.—You cannot rob the English Branch Council.

Dr. HAUGHTON.—You can rob anybody by Act of Parliament.

Dr. HERON WATSON said that the expectation of the framers of the original Act was that where a man took his diploma there he would register, and he thought the Council should avail itself of the hint which Sir Lyon Playfair had given, and enable that gentleman to go to Parliament with the decision of the Council to back him.

The motion was then put and lost, nine voting for it and ten against it.

The PRESIDENT said that if any serious impediment to the Amendment Bill occurred at the present time, it would necessarily not pass this session, and it was fortunate that the Council was not pressing him to make alterations.

The Council then adjourned.

SATURDAY, JUNE 5TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

Dr. QUAIN proposed the adoption of the Pharmacopœia Committee's Report. He said the sale of the Pharmacopœia had already resulted in a considerable profit, amounting to £321. If such a rapid sale and so large a profit could have been anticipated the Council would have been justified in charging a smaller sum for it. An honorarium of £500 was voted to the committee when the previous Pharmacopœia was published, but he hoped that nothing of the kind would occur on this occasion.

Dr. A. SMITH seconded the motion, which was agreed to.

Report by the Pharmacopœia Committee.

Dr. ATTFIELD attended the committee.

"The committee report that a statement laid before them shows that of the edition of 20,000 copies of the Pharmacopœia of 1885 about 19,000 copies have been disposed of. It will therefore be necessary to prepare for a re-issue of the work, and they recommend that the Executive Committee be authorised to take the necessary steps for the purpose.

"The committee recommend that the *errata* contained on

Digitized by Google

the slip issued with the first reprint of the Pharmacopœia be inserted in the text of the work, together with some further *errata* now submitted to and approved of by the committee. They further recommend that the slips of *errata* be kept in stock for distribution to former purchasers of the work, and for insertion in the still unsold copies.

"With reference to the proposed annual report on such changes or additions as may be required in future publications connected with the Pharmacopœia, the committee report that so short an interval has elapsed since the publication of the work that it will be undesirable to submit a report until next year. The committee have remitted to the sub-committee the duty of making the necessary arrangements for this purpose.

"Finally, the committee report that the sum of £2713 8*s.* 5*d.* has been expended on the production of the present edition of the British Pharmacopœia, and that the sum of £3534 13*s.* 7*d.* has been received from the sale of the same, leaving a balance in favour of the work of £821 5*s.* 2*d.*

"June 2nd, 1886." "RICHARD QUAIN, M.D.

On the motion of Dr. QUAIN, seconded by Mr. SIMON, the following report by the Finance Committee was adopted:—

"The Finance Committee report that the income of the General and Branch Councils for the year 1885 (ending Dec. 31, 1885) has been £11,113 8*s.* 9*d.*, an amount which exceeds by £2689 6*s.* 6*d.* the income for the year 1884. The expenditure during the year 1885 has been £12,083 16*s.* 4*d.* The committee has, therefore, to report to the Council that the expenditure during the past year has been in excess of the income by £970 7*s.* 7*d.*

"As regards expenditure, the largest item of increase has been that caused by the publication of the new edition of the British Pharmacopœia. This excess amounted to £2279 18*s.* 3*d.*, which has been, or is now, in process of being recouped. The expenditure involved by the visitation of the final examinations of the universities represents an increase of £2207 14*s.* 4*d.* An increase in expenditure has also been incurred to the amount of £198 7*s.* 6*d.* on account of the investigations of the Statistical Committee. In law expenses there has been an increase of £159 10*s.* 11*d.* In general printing there has been an increase of £54 6*s.* 7*d.* The only items which show a diminished expenditure for the year 1885, as compared with 1884, are a decrease of £110 1*s.* 8*d.* in fees to members of the Executive Committee in consequence of fewer meetings having been held, and a decrease of £62 in the fees paid to members of the General Council. While, therefore, the increase of expenditure is £5152 0*s.* 3*d.*, the decrease amounts to only £262 13*s.* 5*d.*, leaving an actual increase in expenditure of £4889 6*s.* 10*d.*

"The average yearly income of the General and Branch Councils during the last seven years exceeds the average yearly expenditure by £1494.

"*Dental Finance.*—In the receipts (£507 13*s.* 2*d.*) of the Dental Registration Fund for the year ending December 31st, 1885, there is a decrease of £78 4*s.* 9*d.* over those of the previous year. On the other hand, the expenditure (£713 15*s.* 10*d.*) has been less by the sum of £182 6*s.* 11*d.* The deficiency of income for the year amounts to £206 2*s.* 8*d.*, as compared with a deficiency of £310 4*s.* 10*d.* in 1884.

"June 3rd, 1886." "RICHARD QUAIN, M.D., Chairman.

Sir Dyce Duckworth was appointed a member of the Pharmacopœia Committee.

The following report by the Statistical Committee was adopted:—

"The Statistical Committee are enabled to report that, by the continued labours of the Registrar, assisted by the accurate statist whose services were engaged last year, tables corresponding with those already published for the year 1871 have now been prepared for the years 1872, 1873, 1874, and 1875. These tables, it is recommended, should be published in the form of an appendix to this year's volume of the Minutes of the Council. In the further prosecution of this inquiry, it has been found desirable, for the sake of accuracy, to make some slight additions to, and corrections in, the data and the summary given for the year 1871. These do not invalidate any of the general conclusions hitherto arrived at, but care has been, and will be, taken to keep the returns for the succeeding years in conformity with those now corrected for 1871. It is proposed, in the interval between the present and the next meeting of the Council, to prepare, on the lines of the summary for the year 1871, a review of the statistical results of the several years of the entire quinquennium, and also a comparison between those of the first and the fifth year. This will complete the task of the committee, so far as it has been at present planned; for it will be at once understood that, if the inquiry were now pursued into the ensuing quinquennium, sufficient time would not have been allowed to develop the ultimate stages in the destiny of the students registered in those years respectively; and, what is of more moment, the defect in question would affect the later years in gradually increasing ratios. The committee will, however, be prepared, on presenting their next report, to make, for future investigations, such suggestions as may then seem to be desirable. In conclusion, the committee are glad to learn from the Registrar that the 250 copies printed of their first report have nearly all been distributed (or sold), a fact which attests the general interest taken in the inquiry which has been entrusted to them.

"June 3rd, 1886." "JOHN MARSHALL.

Dr. STRUTHERS moved: "That it is desirable that the Council should have information, so far as possible, as to the standard of attainment required in the several subjects included in the various preliminary examinations recognised by the Council as qualifying for admission to the Medical Students' Register—as by the inspection of the examination-papers and of a selection of the answers of candidates; and that it be delegated to the Executive Committee to make the necessary arrangements for carrying out this resolution."

The motion found no seconder, and the Council then adjourned.

MONDAY, JUNE 7TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

Mr. MARSHALL brought up an *interim* report of the Visitation of Examinations Committee. It referred only to some of the more important questions raised by the visitations, a full analysis being deferred to the next meeting of the Council.

The Council resolved itself into Committee, in order to take the report into consideration.

Dr. CHAMBERS said the Visitors, in order to determine on the general efficiency of an examination, merely took one sample, and he had heard it said on good authority that in many cases the sample was not a fair one. It was an important argument that the number of those graduates who afterwards became men of mark was evidence of the thorough efficiency or otherwise of the examination. There could be no question in an educational body like the Council as to who were men of mark. The term would include the teachers at the various medical schools, those who were cited as authorities, those who had received honours from the State for their services to science, and the members of the Medical Council. He had made out from the Medical Register and the Medical Directory a list of the men of mark, and divided them according to the universities from which they came. The percentage of men of mark among the graduates of all the universities was 5·2, while among the general body of practitioners the percentage was 3. The universities differed greatly among themselves, varying from 1·1 per cent. to 32·4 per cent., which was the percentage of the University of Oxford. The most industrious and intelligent pupils would always choose the examination where there was the least element of chance.

Dr. DUNCAN said he thought the Council had nothing to do with the universities except so far as they were licensing bodies. Their only concern was whether the university examinations were sufficient to test a man's sufficiency to be entered on the Register.

Dr. STRUTHERS said he was not in a position to discuss the report, which had only just been placed in the hands of the Council.

Sir DYCE DUCKWORTH hoped that the representatives of all the universities would express their views on the subject in order to assist the Council in the consideration of the report.

Dr. CHAMBERS said a reference had been made by the Visitors to the fact that at the Oxford examination a classical paper had been set—a translation from Hippocrates and some Latin author. That, he thought, was not really necessary, the candidates having been previously examined in Latin and Greek; but it was a survival from past times, and would probably soon disappear, as would also, he hoped, the custom of requiring candidates to write prescriptions in full instead of by contractions.

Digitized by Google

Dr. HERON WATSON asked if Dr. Chambers had directed his attention to the remarks of the Visitors with reference to the Oxford surgical examination.

Dr. CHAMBERS said that a surgical examination had only been recently introduced at Oxford, and they had not fully got into working order. They thought they had better begin by having an examination sufficient to meet the requirements of the Medical Act, but it certainly was not yet sufficient for a university degree in surgery. There was some difficulty at the University in getting an adequate knowledge of midwifery, the examiners not being allowed, by the bye-laws, to take the testimonials of other bodies.

Mr. MACNAMARA said the Visitors had been given to understand that it was under the consideration of the University authorities to pass a statute to establish a higher degree in surgery, for which there would be a special examination.

Mr. TEALE said the Oxford degree was originally only a medical one. When he was appointed surgical examiner there, in deference to the wish of the Medical Council that every person going on the Register should be examined in medicine, surgery, and midwifery, he considered it his duty to examine only in that part of surgery which was in contact with medicine. When the Council recommended that no examination should put anyone on the Register who had not been completely examined on the three subjects, the University was to a certain extent in a period of transition, which had not ceased, and it had been determined not only to fully examine in surgery, but to have more than one surgical examiner, and to give a degree in surgery, so that the criticisms of the Visitors, as far as they pointed to improvements, were answered by the fact that these alterations were about to be made. It so happened that at the last examination all the candidates were members of the College of Surgeons, and the University authorities had seriously mooted the point whether they should not require all their graduates to pass the conjoint examination of the Colleges of Physicians and Surgeons. He was personally strongly impressed with the necessity of economising the examining powers. Why could not the mere routine matters be taken for granted? Why could not the University, for instance, take the midwifery and surgery at the hands of another board?

Dr. DUNCAN.—Why not take everything at the hands of everybody else?

Mr. SIMON said the general sense of the medical profession as to the necessity of not having lopsided qualifications had been operative at the universities as well as at other places.

Dr. HUMPHRY said he had very few remarks to make with reference to the Cambridge examinations. The Visitors had remarked upon the absence of any examination in clinical surgery for the M.B. degree, and on the insufficiency of the study of midwifery. Since the report of the Visitors the University authorities had decided that in future clinical surgery should form a subject in the examination for the M.B. degree, and that the professor of surgery should be one of the examiners for that degree; also that the attendance on twenty (instead of ten) midwifery cases should henceforth be required.

Mr. MACNAMARA said there was no obligation on the part of the Bachelor of Medicine to pass on to the examination for the degree of Bachelor of Surgery, and the first of those examinations was not in itself sufficiently exhaustive, surgery being a minimum quantity.

Dr. HUMPHRY said that the greater number of the candidates did not pass on to the degree of Bachelor of Surgery, but he hoped that, as surgery became more and more developed, a larger number would do so.

Dr. HERON WATSON referred to the remark of the Visitors in regard to the hesitation of the Cambridge authorities to sanction examinations in midwifery and gynæcology, and to the reply of the University: "The Board think it impracticable, if only out of consideration to the female patients, to require the candidates to make gynæcological examinations in the presence of the examiners." He was thankful to find such a reluctance on the part of the authorities to sanction such a proposal.

Dr. HUMPHRY, in reply to a question by Dr. Struthers, said that the Cambridge University did not require that its graduates should obtain all their instruction at the University, but it required residence for a given period.

Dr. PYLE said he had no remarks to make with regard to the Durham examinations, the report of the Visitors having been of so favourable a character.

Sir DYCE DUCKWORTH said he thought that the Durham examination of fifteen-year practitioners was the least satisfactory part of the examination.

Dr. HERON WATSON thought that the examinations alluded to by Sir Dyce Duckworth, being for a higher qualification, did not come within the scope of the Visitors' functions. He should be glad if the letter of instruction to the Visitors could be laid before the Council.

Mr. MACNAMARA said Dr. Watson's contention would seem to be that if a gentleman had his name on the Medical Register no notice should be taken of his seeking an additional qualification. Clearly the Council were entitled to know under what conditions the higher qualifications were conferred, and under the directions they received from the President the Visitors were bound to inquire into the examinations for degrees, no matter how old the candidates were.

Dr. HERON WATSON said if the Council intended to visit all the examinations for so-called higher qualifications, it would be necessary in future to send to the examinations for fellowship of the College of Surgeons and membership of the College of Physicians. That would be a serious matter to contemplate, especially now that they knew the cost of the last visitations.

Mr. MACNAMARA said that the Council was entitled to know on what terms every qualification was given which entitled a man to be on the Register. At the College of Surgeons in Ireland not only was a fellowship given by examination, but a fee was charged for it, and the Council was bound to see that they were not entirely influenced by their pocket in granting a higher qualification.

Mr. SIMON said the Council was entitled to inquire into all examinations, but the question was whether, on a special occasion, the Visitors were requested to examine into certain matters.

The PRESIDENT, on behalf of the Council, expressed their thanks to the Visitors for the courtesy, kindness, and cheerfulness with which they undertook the work.

Mr. MARSHALL said the committee had, in their report, called attention to the fact that some of the Visitors had exceeded their instructions.

The letter of instruction having been read,

Dr. STRUTHERS said that the School of Medicine of the Durham University was at Newcastle, and it did not appear necessary for the students to reside at Durham. His own idea of university education was founded on residence as a primary condition.

Dr. QUAIN said that the students might reside in Durham and yet attend the school in Newcastle, the journey only occupying twenty minutes. After all, the great thing to trust to was a thoroughly good examination.

Dr. A. SMITH thought that Mr. Macnamara was fully entitled to visit the examinations for higher qualifications.

Dr. HERON WATSON called attention to the remark of the Visitors of the Durham examinations: "In our opinion, the power of stopping a candidate after his written examination, on the adjudication of his case by the whole court of examiners, is both wise and advisable." A consideration of that question, he thought, was most desirable.

Dr. QUAIN (in the absence of Sir Wm. Gull) said he had but few remarks to make on the visitation of the examinations of the University of London. One criticism of the Visitors was that the examiner was not present to criticise the mode in which the candidate conducted his clinical examination. The rule was, and he thought it was a good one, that the candidate should be left to make an independent examination, and to furnish a report on the diagnosis and the proposed treatment. He had no one at his elbow to harass and disturb him. It was further said that insufficient time was given in certain cases, and that the answers were mere guesses. That, he thought, was an idle piece of criticism, the cases being perfectly plain and obvious. The Senate had, however, accepted the suggestion of the Visitors that there should be a more complete examination in surgery for the M.B. degree.

Mr. MACNAMARA said that with regard to the points mentioned by Dr. Quain the Visitors were of opinion that their remarks were justified. They were especially struck with the entire want of supervision on the part of the examiners, and also with the absence of curricula, which they regarded as a great defect. Further, there was no *viva voce* clinical examination in clinical medicine; nor was the candidate asked the grounds on which he had arrived at his diagnosis; nor was there any test in regard to the use of instruments and appliances.

Digitized by Google

Mr. TEALE said that the great variety of methods in which clinical examinations were carried out would form the basis of a very important report, and a subject for careful consideration by the Council at some future time. The selection of cases for examination was a very serious matter. It was, therefore, very important that some common decision should be arrived at as to the general lines on which clinical examinations in surgery and medicine should be conducted.

Dr. QUAIN said that, though the candidates were left to themselves when conducting clinical examinations, personal supervision was exercised, as the examiners usually went round the wards three times each half-hour. The oral examination was based on the clinical as well as on the written examinations. Mr. Macnamara had said that the examination in surgery was insufficient, but the reply was that all who passed at the last examination would have passed at the College of Surgeons, and that statement was signed by Sir James Paget and two Fellows of the College of Surgeons, who surely knew more about it than the three strangers who visited there.

Dr. HERON WATSON.—What opportunity had Sir James Paget of knowing what was done?

Dr. QUAIN said he had the papers before him and questioned the examiners. Five years' medical study was required, but it was left optional to the students to find out where they could get the best lectures. They must, however, attend lectures on six subjects, and that system was preferred to any dogmas laid down by those who had an interest in the fees paid for lectures. No doubt it was to be regretted that the men were backward in Latin; but he believed that not 50 per cent. of the students who obtained qualifications could write a decent prescription in Latin. Still, a man might be a very good doctor without being a proficient in Latin.

Mr. SIMON said the London University had been looked up to as a superfine one, and the men who went there for the medical qualification must have previously matriculated there.

Dr. HUMPHRY was extremely surprised to find that there was no *vivâ voce* clinical examination in medicine. He was certain no man could pass the College of Surgeons unless he were able to pass a clinical examination on patients.

Mr. MACNAMARA said that it was impossible to examine clinically and in a thorough manner thirty-six candidates in three hours. The Visitors were forced to the conclusion that the surgical part of the examination was insufficient as a test of fitness for practice. There was no clinical examination whatever in surgery. To put a man in the first class who was reported as "decidedly weak" in surgery was, to say the least, open to animadversion; whilst to give a registrable qualification to a candidate pronounced by competent authority "bad" in surgery must be highly objectionable.

Dr. QUAIN asked Dr. Humphry how long it was since surgery was first required for a degree of M.B. at Cambridge.

Dr. HUMPHRY said it had been a special subject of examination for ten or more years.

Dr. QUAIN reminded the Council that they were not sitting to judge of the competency of the examiners. The question was what were the results of the examinations, and were those who passed them qualified to practise.

Sir DYCE DUCKWORTH said the examiners themselves confessed to a blot having been hit by the Visitors, and allowed that oral examination might, within reasonable limits, be increased with advantage. He himself attached much importance to *vivâ voce* examination at the bedside, and clinical investigation was very much assisted by the examiner supervising the candidate at the bedside.

Dr. QUAIN said it had been freely admitted that oral examination might be extended, and that more surgery might be included in the M.B.; but was it worth £370 to secure that, for that was the sum it cost?

Dr. STRUTHERS said it was worth £300 to find the University of London out. (Laughter). They had all been told to look up to the University of London as a model institution. Some of them, however, had taken the liberty of saying that it was not a university at all, but only an examining board.

Dr. QUAIN.—That is what it was intended for.

Dr. STRUTHERS.—A university means a teaching place. People coming from abroad sometimes ask who is the professor of anatomy at the University of London, and they have to be told "no one."

Dr. QUAIN.—You are one of the professors of anatomy in the University of London, for we examine your pupils.

Dr. STRUTHERS said he did not mean to contend that it was not useful to have one institution on the footing of the University of London to meet cases of hardship, but there ought not to be more than one. The examinations, however, in such an institution should be thorough. For himself, he would not undertake to give an opinion with reference to a candidate unless he had him a long time under examination, or had him before as his teacher. Large sums of money were given to the university to pay its examiners handsomely in order that they might do their work thoroughly, and it was believed that the examination was as perfect as it could be. When, however, he read the report of the committee, he was amazed at some portions of it. He wished to call attention to the reference in the report to the subject of compensation, simply premising that it was one of the recommendations of the Council that deficiency in one department could not be compensated by excellence in another. The Visitors stated, with reference to the University of London, that the principle of compensation was in some cases freely admitted, as in the case of a candidate who was marked in medicine as "very doubtful," who had received nothing in his *vivâ voce* examination, and whose mark in obstetrics was "doubtful," but who passed in the first division. Another candidate whose medicine was "rather doubtful," and surgery "bad," passed in the second division; and a third candidate whose obstetrics was marked "reject," passed in the first division. With reference to the clinical examination, the Visitors reported that they were "unsatisfactory as a reliable test of practical capacity, and quite inferior to similar examinations elsewhere." After making certain recommendations they added—"This could not be done save at considerable expenditure of time, trouble, and money, but until it is done the Visitors are of opinion that it is impossible to look upon these examinations as thoroughly satisfactory." With regard to the oral examination the Visitors were of opinion that it would be better to have more prominence and value given to it. The longer he lived the more he valued oral examination; indeed, he considered it of twice as much value as the written examination. He would undertake to get more out of a man as to his knowledge of anatomy in twenty minutes than could be obtained by three or four hours working at a paper. He supposed that the explanation was that the time of gentlemen living in London was particularly valuable, so that they were not able to devote so much of it to the work as was done in the north. The Visitors also reported that there was no clinical examination in surgery for the M.B. degree. He could not believe in any examination in surgery that had nothing clinical in it. The University authorities, however, stated that their surgical examination for the M.B. degree related to "surgery on the medical side," an expression which he confessed he could not understand. In Scotland they never had a Bachelor of Medicine examination without a surgical examination in connexion with it.

Dr. QUAIN asked how long that had been the case.

Dr. STRUTHERS said that he himself was examined by Syme and Miller.

Dr. QUAIN.—As a general practitioner.

Dr. STRUTHERS said that Dr. Quain had been the head and front of the conjoint boards that had been endeavoured to be thrust upon them and that were to heal all the sores of England, and Scotchmen had been represented as standing in the way of progress. Another point upon which the Visitors had reported was that there was no *vivâ voce* interrogation or test in regard to manual dexterity as to bandages, splints, &c., which was certainly a great deficiency. The subject of midwifery was also commented upon, and the Visitors stated: "It may be noticed that all that the University requires in the matter of obstetric examination is evidence of having conducted at least twenty labours. This does not involve hospital attendance or clinical instruction, inasmuch as certificates are received from any legally qualified practitioner of medicine, nor is it compulsory for a candidate to have attended a course of lectures on obstetrics or gynæcology." Speaking of the midwifery examinations, the Visitor said: "These examinations gave me a fair opportunity of judging of the average quality of the candidates, and in this I must say I was much disappointed." He also stated that the examinations were not more than of average severity. The general inference was that the examination in midwifery was weak, and that the average was not good. Scotch universities had been visited and criticised from London; and now the turn of the London University had come, and

Digitized by Google

with what a result! As to the statement of the authorities about the evil effects of compulsory attendance at lectures, that was merely platitudinal. It was painful that such a university should not come up to the average of the despised corporations. They had hitherto looked up to the University on the principle of "*Omne ignotum pro magnifico.*" It was now discredited in the house of its friends, and was not regarded, even in London, as a satisfactory institution.

Dr. QUAIN.—Why?

Dr. STRUTHERS.—I leave the London schools to reply to that question.

Dr. QUAIN said he would appeal to Dr. Duncan to reply to the strictures of Dr. Struthers on the subject of midwifery and obstetrics. He had been an examiner at the University for four years, and if he had had anything to correct or suggest his advice would have been followed. The great complaint made of the University was that its examination was too strict, and the students said if it were not reduced they would have to go to Scotland to pass. They had tried to found a university in London that would give degrees more easily than the present one. It was the old story of the battle of the shops. The Visitors had found fault with nothing that did not admit of a satisfactory answer, except with regard to two points, as to which the Senate was ready to follow their recommendation. The reports consisted mainly of opinions; but he would appeal to facts. It appeared from the statement of Dr. Chambers that there were more men of mark going from the London University than from Scotland. It was also the fact that many students went to Scotland in order to get their degrees more easily. The London University had the best examiners in the world, and it was a matter of regret that they were obliged to reject so many candidates. Happily the University was only an examining body. In Scotland the teacher actually examined his own pupils and gave them a licence to practise. What confidence could be placed in a system like that? He considered it a great scandal.

Dr. WATSON moved the adjournment of the debate.

The PRESIDENT, before putting the motion for adjournment, said he had noticed with great satisfaction the good-humoured and frank criticism on both sides. The Council had deliberately resolved that the different divisions should report on each other. That course had been adopted, not with the slightest wish that fault should be found unreasonably, but with the desire of bringing to bear on the subject the experience of the three divisions. He hoped that that spirit would prevail during the remainder of the discussion.

The debate was then adjourned.

TUESDAY, JUNE 8TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The PRESIDENT desired to call attention to the position of the Medical Bill. It was impossible to say what its fate might be, but under any circumstances the important educational work of the Council, on which it was at present engaged, would not be interfered with. He presumed it would be the desire of the members to meet again in the autumn. By that time the mass of information before the Council would be still further increased, and there would be ample work to be undertaken.

The Council having resolved itself into committee for the further consideration of the report by the Visitors of the final examinations of the University of London,

The PRESIDENT said they all regretted very much the absence of Sir William Gull through illness, and especially so in view of the discussion that had taken place with reference to the University of London, of which Sir William Gull was the representative at that Council. He had visited Sir William on the previous evening, and during their conversation he made a short statement, not directly relevant to what had taken place at the Council, but extremely relevant to the whole educational question, to the relation of the universities and corporations generally, and especially of the University of London, to the corporations of London. Sir William said he would much like to see the universities so associated with the practical bodies in London as one of the great clinical centres, that those who passed the matriculation examinations and the preliminary scientific examination, specially arranged for the purpose, should, with the co-operation of the Colleges of Physicians and Surgeons, obtain their degree. This would help to associate the professional education with the higher general scientific education of the country, and he hoped and expected that by such fusion and co-operation they might raise both the scientific and practical mind of the whole of the profession. He referred especially to the University of London, separated, as was so often said, from the general wants of the profession. On this account it would certainly be hereafter suggested to the University of London to make some such proposals to the Colleges of Physicians and Surgeons as might seem to be a real help to promote scientific and practical education and examination throughout the country. The President added that he understood Sir Wm. Gull to make those remarks because he was well aware that the visitors had found much fault with the system of clinical examination, and in consequence had been carefully considering in what way the practical and scientific systems could be best combined.

Dr. WATSON, in resuming the debate on the visitation of examinations, said he had always thought that the University of London was a most perfect institution, but that idea had been dispelled by the report of the Visitors. It was nothing more than an examining board, and had not so real an existence as the College of Physicians or the College of Surgeons. He wished to emphasise the criticisms of other speakers, and to refer to one point to which they had not alluded in connexion with the arrangements for conferring the Bachelorship of Medicine. It would be seen that the student might go up for examination without having attended a course of lectures on descriptive and surgical anatomy, or any course upon surgery and medicine. It was remarkable that the regulations of the University should be so lax as not to ensure the requisite attendance upon lectures on subjects that were absolutely essential to the practitioner.

Mr. MACNAMARA, in replying to the remarks of Dr. Quain that the reports of the Visitors contained nothing but opinions, called attention to the statements of fact in the reports with reference to compensation, and challenged Dr. Quain to contradict them. He also referred to the statement of the Visitors that the examiners were not responsible for the shortcomings pointed out, which were simply the outcome of the university regulations, the duties of the examiners being discharged in a most conscientious manner. It was for the Senate to ponder on the report, and see if it could not improve its arrangements. The purely scientific examinations were fully up to the mark, but the important thing was to secure a good sound professional education. The present contest was not so much a battle of shops as a contest between lecturers and authors. Dr. Quain had written a big book, and no doubt thought that everything was to be found in it.

Dr. QUAIN.—I have not had a farthing of profit from it.

Mr. MACNAMARA.—But £200,000 worth of reputation.

Mr. MARSHALL asked whether it was the case that the Senate of the London University contemplated introducing clinical examinations in surgery.

Dr. QUAIN said it was a suggestion of the Medical Council, and he had no doubt it would be adopted.

Mr. SIMON drew attention to the statement in the report that a candidate was passed and classed in the first division whose mark in obstetrics was "reject," as being in contravention of the recommendation of the Council that knowledge in one subject should not be allowed to compensate for ignorance in another, and also as being an apparent breach of the regulations of the University itself, which said that candidates should not be approved by the examiners unless they had shown a competent knowledge in all the subjects of examination. With reference to compulsory attendance at lectures, his sympathies were with the London University. No doubt lectures were useful, but he doubted the wisdom of enforcing compulsory attendance.

Dr. DUNCAN said the Council had of late years been dominated by the spirit of the University of London to a very prejudicial degree, and he was very glad to see a great change in the direction of the efforts of the Council. That medical education could be carried on without lectures he entirely disbelieved, and in spite of the *doctrinaire* remarks of Dr. Quain and Mr. Simon he would defy them to produce a single man who had passed the London examination who had not been educated by lectures. They had been told that there was no such desire in London for lectures as there was in Scotland, but that was because the appetite had not been stimulated by satisfaction. He was quite sure that if good lectures were given students would attend them diligently, the best men being the most regular in their attendance. Speaking as an examiner of considerable experience, it seemed to him that the representations in the

Digitized by Google

Visitors' reports showed that there must have been a great change since he had fulfilled that office. It used to be the case that a student who was rejected in midwifery was rejected altogether. He asked whether that system had been changed in the University of London.

Dr. QUAIN said it had not been changed.

Dr. DUNCAN said he had never heard of anything like "compensation" when he was an examiner. Compensation was the result, and the necessary result, of the arrangement of students in classes. There was a very grave fault in this respect in the management of the University of London, where the necessary result of this bad system was this, that in a year of bad men a bad man got easily into the first class; whereas in a year of good men a good man was put down into the second class. This arose from their taking the ten or a dozen students who had attained the highest marks and making them into a first class, no matter whether their percentage of marks was high or low as compared with the total possible number.

Dr. QUAIN defended the University of London from the strictures passed upon it, and appealed to the improvement which had taken place in medical education since its establishment as a proof of the beneficial influence that it had exerted. It was the first body to establish the degree of Bachelor in Surgery.

Dr. HAUGHTON said that it had been established in Dublin ages ago.

Dr. QUAIN said that the University of London gave its first Surgical Scholarship in 1866. After referring in detail to some of the criticisms of the Visitors, he said that the best test of the efficiency of the University of London was to be found in actual results. There was no higher class of men than the Fellows of the College of Physicians of London. He had gone through the list to see how many had come from the different universities, and the numbers were — London 70, Cambridge 30, Edinburgh 28, St. Andrews 24, Oxford 22, Aberdeen 11, Dublin 6, Glasgow 5, Durham 1, foreign (mixed) 17. The following eminent surgeons, holding appointments in London, belonged to the London University—Mr. Rivington, Mr. Marcus Beck, Mr. J. Rickman Godlee, Mr. Pearce Gould, Mr. Howse, Mr. Pepper, Mr. Lane, Mr. Stanley Boyd, Mr. Victor Horsley, and Mr. Clement Lucas. Baronetcies had been conferred upon several distinguished members of the London University. Indeed, no institution had sent out a more distinguished body of men.

Dr. HAUGHTON admired Dr. Quain's defence of the London University, and the more so as the University was certainly in the wrong. The state of the law, however, was to blame, and when that was changed all the universities and bodies would be compelled to apply a severe practical test in medicine, surgery, and midwifery before registration.

Report on the University of Edinburgh.

Dr. STRUTHERS said the Visitors had spoken of the University and of its examinations in the very highest terms, but in one sentence in the body of the report they said that the surgical appliances used in anatomy were behind the times and rather old-fashioned. That was a mistake on the part of the Visitors, and the University, in their reply, had given a complete answer to that statement, and had shown that they had ample surgical splints and other appliances, and of the most modern kind.

Dr. QUAIN pointed out, as bearing upon the subject which the Council had just been considering, that three of the most distinguished professors of the University of Edinburgh—Professor Crum Brown, Professor Greenfield, and Professor Turner—were found in the ranks of the University of London.

Dr. HERON WATSON pointed out that the report opened up a wide question—namely, the principle which existed in the Scotch universities of the teachers examining their own pupils. This had always appeared to him to be a serious blot. However complete and satisfactory the system might be in other respects, and however absolutely careful the professor might be to avoid being swayed by any personal feeling, he was sure that this must exercise an injurious influence on the minds of the students, because it practically compelled them to attend the courses of lectures given by their teachers in order that, with a view to the examination, they might become acquainted with their peculiar methods and ideas. If the teacher were present he should certainly take no active part in the examination of [illegible]

[illegible] phatically been brought before the Council, and hoped that it would insist that no examiner should be the examiner of the students in the subjects in which he taught. He suggested that the Council should refuse to register any qualification granted where the students had been so examined.

Dr. PETTIGREW thought that, if examiners were appointed to examine apart from the teachers, the teaching would be injuriously affected. The teacher would be "cribb'd, cabin'd, and confin'd" in his endeavours to satisfy the examiner. The number of examinations was too great, and the tendency was to increase them. The plan of having an equal number of professorial and non-professorial examiners was, he thought, the best way of meeting the difficulties of the case.

Sir DYCE DUCKWORTH, giving his experience as an examiner for five years in the University of Edinburgh, stated that he considered the work was there carried out in the most satisfactory manner. The examinations were carried out by an independent examiner in conjunction with a professor. He believed that to be the best examination system for medical students—to have the professor alongside of another independent examiner, and both of them to examine each candidate. He believed in the supreme value of the candidate coming before the man who had taught him his subject, and in an independent examiner being present to witness the examinations; the system was found to work most admirably; but in order that it might be thoroughly fair the extra examiner should never under any conditions become the creature of the professor. He must be a perfectly independent man, to whom consideration should always be shown and to whom the professor must defer. In his own experience he never had any occasion to make any remonstrance in any matter that was not immediately deferred to. He pointed out what was now becoming a most serious question—viz., that Edinburgh was now drawing so many students from all parts of the world within her walls that she was slowly asphyxiating and choking herself. The crowds were so enormous that the difficulties of teaching and examination were becoming stupendous, because of the utter impossibility of finding clinical material, medical, surgical, or obstetrical, properly to educate these enormous masses of intelligent students.

Dr. DUNCAN thought that a great deal of the success at Edinburgh depended on the excellence of its teaching. There was no doubt a want of clinical material, but the obstetrical material was abundant. The theoretical teaching of midwifery was perfect. The students were required to pass through the Maternity Hospital, where the cases were managed in a manner approaching perfection. It was a great advantage to all concerned for the teacher to have a great share in the examination, but the independence of the assessor was not always sufficiently assured. The practice of using the uterine sound in the examination, referred to by the Visitors, he could not approve. There was nothing to show that the same woman might not be subjected to the same operation by a succession of students.

Mr. TEALE expressed his concurrence in the remarks of Dr. Duncan in regard to the use of the speculum.

Dr. HALDANE thought that non-professorial examiners should be elected by totally independent bodies. They were sometimes younger than the professors, and many of them had been assistants to the professors, and therefore unduly deferred to them. A professor, when examining, could often tell whether a particular candidate had attended his class, and might be influenced by the consideration. That had great effect upon the students. He thought that all the fees should go into one fund, out of which the professors should be paid a fixed salary.

Dr. PETTIGREW had never as a non-professorial examiner experienced any difficulty. He agreed, however, with Dr. Haldane, that it would be better that such examiners should be appointed by an independent body.

Dr. STRUTHERS, in reply, said he would not care to be a teacher unless he was also one of the examiners. The professors were examiners in the great German universities and the other universities of the continent. The object of a university was to try to get the best man in professorship, and that man of course must be an examiner. They could not keep up the style and tone of the teaching if it were not so. He should be most happy to see examinerships additional to the professors, appointed by an outside authority, and thought that if the Crown or the Medical Council should appoint such examiners it would be an improvement [illegible] these system that could be devised [illegible]

Digitized by Google

being one of the examiners with an outside examiner, one man who knew the student well and was his teacher, and another man who knew nothing about him. That was the ideal that he had long fought for, and which was very well worked out in the Scotch universities at present. If he was to be a mere grinder for another man's examination he would not care to teach—he would rather be in a shop.

Mr. MACNAMARA called attention to the statement of the Visitors at Edinburgh that the competency of the candidate in practical surgery was not sufficiently tested, the student not being asked to do the simplest operation on the dead subject. That, he thought, was a grave defect in an examination for M.B. in a large and leading university like that of Edinburgh. It also appeared that there was no living body present on which the student could, when required, compress one of the large arteries. There was only one living patient who was brought in for a student to apply a splint in a case of fracture of the lower jaw. The student could not do it, but his mark was *satis*. Another point mentioned was the absence of any ophthalmoscope or laryngoscope.

Dr. STRUTHERS explained that the Visitors were only present at the examination of eleven candidates out of 230. The fact was that the live model was waiting in an adjoining room, and was used in one of the very few cases which the inspectors saw. He contended that it was the teaching, after all, that was of importance, and no student came up for examination who had not carefully dissected a whole body under his (Dr. Struthers') eye. As to the laryngoscope or the ophthalmoscope, the use of these things was systematically taught in their schools, and there was abundant opportunity for becoming acquainted with their use.

Mr. SIMON took exception to the idea that all that a university had to do was to teach. If so, then let the University decline to examine, and that would entirely meet the view of some of the members of the Council.

Dr. MC VAIL said that the custom of making teachers examiners was, in Glasgow, greatly hindering the utilisation of the material available there.

Dr. HERON WATSON reminded Mr. Macnamara that a report had some years ago been prepared with reference to the supply of dead bodies, but under the circumstances it was not thought desirable to make it public. That might, perhaps, explain the absence of examinations on the dead subject at some of the universities.

Dr. PETTIGREW, referring to the report of the Visitors to Glasgow, said he had no remarks to make upon it, the authorities there being satisfied with the answers they had already given.

Dr. STRUTHERS said, having gone through the report very carefully, it was impossible not to see that the way in which the examinations were conducted was an admirable one. He had read no report with greater satisfaction.

Mr. MACNAMARA, as one of the Visitors, spoke of the admirable way in which the examinations were conducted. As Visitor in surgery he could affirm that nothing could have been better than the manner in which the examinations in that branch were carried out. One part that was somewhat open to criticism was that the student's examination should be proceeded with long after it was clearly proved that he could not pass. The examiners themselves did not approve of this course, but they were helpless in the matter. The result, of course, was a great waste of time.

Dr. PETTIGREW thought that if a student failed in obstetrics, but passed well in the other subjects, he should be permitted to come up again in obstetrics. He hoped that the Committee on the Visitation of Schools would formulate some scheme by which examiners and students might be saved the necessity of again going over subjects that had been already sufficiently well passed.

Dr. BANKS said that in the University of Dublin, if a man passed well in other subjects, but failed in one, he was put back, but not re-examined upon the subjects upon which he answered well. It was a very hard thing for a man who answered well in clinical medicine and surgery, and who might fail upon some less important subject, to have to keep up his knowledge of minute anatomy, and be re-examined upon it at the end of another six or twelve months.

Mr. TEALE thought that the Council would have to face the question of reducing the labour of the examination to candidates, and avoid the waste of examining power.

Dr. HERON WATSON said he had always supported the principle of allowing students to take their examinations as they chose. If the *imprimatur* of the Council were given to that principle, they would probably find the examining boards throughout the kingdom willing to accept it, and to come to such a mode of arrangement as to secure its being carried out with an economy of time.

Dr. HAUGHTON said he thought that a candidate might be allowed to take the larger subjects of medicine, surgery, and midwifery one by one, but that it should not apply to the smaller subjects.

Mr. MARSHALL said that at the joint examination of the Colleges of Physicians and Surgeons a candidate could choose any two out of the three subjects in which to be examined.

The debate was again adjourned.

WEDNESDAY, JUNE 9TH.

At the meeting on the 9th inst. the President informed the Council of the intention of Government to pass, if possible, the Medical Bill before the session closed. The Council then resolved itself into Committee to consider the reports by the Visitors of the final examinations. The discussion on the Glasgow examinations was resumed, after which the report on the University of Aberdeen was considered, the healthy tone of which school and of the examinations in connexion with it being earnestly testified to by Dr. Struthers. Dr. Pettigrew afterwards referred to the visitation of St. Andrews, and pointed out certain statements of the Visitors which he thought were not in accordance with facts. After some remarks from Dr. Chambers, Dr. Duncan, and Mr. Macnamara, the Council adjourned.

THURSDAY, JUNE 10TH.

This afternoon the Council considered the reports by the Visitors of the final examinations of the University of Dublin and the Royal University in Ireland. During the interval for tea, Dr. Haughton and Mr. Macnamara, on behalf of the Royal College of Surgeons in Ireland, presented Mr. Marshall with the Honorary Fellowship of that College in recognition of his valuable contributions to surgical science.

A PENAL CLAUSE TO THE MEDICAL BILL.

To the Editor of THE LANCET.

SIR,—Allow me to thank those numerous gentlemen who so kindly responded to my appeal in support of the penal clause in the Medical Amendment Act. I shall be glad if you will allow me a little space to show the present position of the matter. Sir Lyon Playfair's Bill has passed into the Committee stage, and, so far as the Bill itself is concerned, may be considered as past. This Bill deals chiefly with educational matters. Sir Lyon Playfair says that the reason the Titles Penal Clause was not inserted arose from the fact that no representation in the matter was made to him by any of the heads of universities, colleges, &c. We must hope that this grave omission on their part was purely an oversight. This omission it was intended to supply by Mr. Morgan Howard's Bill, which effectually deals with this clause, though somewhat differently worded, and also with another matter—keeping dispensaries by unqualified persons, &c. But unfortunately this Bill is pertinaciously blocked by Mr. Bradlaugh, and independent M.P.'s inform me that there is no possible chance of its passing. Further parliamentary law prohibits a new clause being moved if another Bill before the House deals with the same subject. Hence the clause brought before the profession cannot be moved for in Committee. If, however, those in charge of the second Bill will consult with Sir L. Playfair and consent to withdraw their Bill and move the insertion of the Titles Penal Clause only, there is no reason to doubt it will be carried. All the M.P.'s whom I have consulted readily admit the reasonableness of the clause and will vote for its admission, and as the Bill is now in Committee stage and cannot be blocked, a little pressure will effect what is so urgently needed. This seems to me to be the only way out of the difficulty, and I earnestly trust in the interests of the profession at large that it may be adopted, otherwise we must appeal to the House of Lords.

I am, Sir, yours truly,

Liverpool, June 7th, 1886. ARTHUR WIGLESWORTH.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, JUNE 12, 1886.

THE approaching election of councillors at the Royal College of Surgeons brings us once more face to face with the important subjects at issue as between the Council and the body corporate. We sincerely hope that Fellows, when voting, will bear in mind what these issues are, their great importance to the well-being of the College and its constituents, and the desirability of voting only for those candidates whose views are known and whose status and strength of character are such as will ensure the carrying out, *after* election, of professions made before.

Our readers are already familiar with the views we hold concerning the present constitution of the Council, and with the great need, as we think, of some radical changes, such as will place the College in more direct *rapport* with the Fellows and Members at large. Among the most desirable changes is that of voting by papers instead of by personal attendance. This, though tardily conceded by the Council, is still in abeyance, and Fellows who wish to vote will have to travel to London in order to do so. For a large number of provincial Fellows this is simply a prohibitory requirement, and they are thus deprived of about the only privilege which is practically open to them. A seat on the Council is of course possible, but can hardly be attained until life is well advanced, and then even only by a very few. At the present time there are three provincial Fellows on the Council, one of whom retires, but will present himself for re-election. There will also be at least one other provincial candidate in the person of a surgeon who has already sought the suffrages of the Fellows on a former occasion. If both these gentlemen should be elected, there will be four provincial Fellows out of a total Council of twenty-four. The principal argument used against the presence of many provincial Fellows on the Council is the impossibility of their taking an adequate share in the work. It must, however, be allowed that the present as well as the former provincial representatives have discharged their duties regularly and punctually. On the other hand, would it not be well for the Council proper to occupy themselves with the larger questions of College policy, and call in for the sub-committees (museum, library, general purposes, auditors, &c., of which the President and Vice-Presidents are *ex officio* members) the assistance of Fellows outside the Council? This would meet many of the difficulties which the acceptance of office imposes on the provincial councillors, and, by utilising the brains of a large number of Fellows in the conduct of College matters, would secure better results than at present. Moreover, it would be a little training for the higher office, and bring out, for the benefit of electors, the aptitudes of those who profess themselves anxious to serve the College.

Of great moment are the questions of granting corporate rights to the Members, and their direct representation in or on the Council. As to the propriety of granting the right to vote to all Members of the College of a certain standing there can be no reasonable doubt. We feel very strongly that, instead of lowering the status of the Fellowship or the Council, or the reputation of the College, its realisation would be a source of strength and advantage in every way. Then, as to the direct representation of the Members on the Council. Shall Members act, or be represented by Fellows chosen by themselves? The former plan will certainly recommend itself to the Members at large, and leave them greater latitude. With the proviso that Members must have twenty years' standing to qualify them for office, the question may well be left optional with them. Experience will soon prove which is the better plan, and which one best realises the object for which direct representation of the general practitioner on the Council is regarded as desirable. The radical changes concerning the granting of the diploma, which the Council have recently initiated in conjunction with the College of Physicians, but without the slightest reference to the Fellows and Members, raise the question how far it is desirable to give the Council such unlimited and autocratic power. The fact that these changes are on the whole wise and good in no way affects the question as one of general policy, but rather emphasises it. Finally, the granting a degree of Doctor to London medical students cannot much longer be delayed; in justice to the men, and not less so to the English schools of medicine, some slight modification of the present curriculum for the double diploma ought to secure this *desideratum*. Elsewhere the title of Doctor is obtainable by an average student after an average examination; in London alone this is not possible.

The settlement of these and many other pending questions can only be obtained by the election of broad-minded councillors, possessing, over and above their surgical qualification, business habits and the moral courage of their opinions. In going over the list of candidates, Fellows will do well to ask themselves which of them, irrespective of school and of personal considerations, are most likely and able to promote the settlement of the issues at stake in the most satisfactory manner, and in the only way which will find acceptance among the constituents of the College, and to vote accordingly. How far have the candidates committed themselves to an expression of the views they hold on these matters, and how far can they be relied upon to carry out after election to the Council the professions made before election? We trust the time is not far distant when candidates for the Council will be expected to give public expression to their views on all current College politics, as do candidates for the House of Commons. We see nothing derogatory to the dignity even of a Fellow of the College in being asked for an exposition of his views, and in being called up occasionally to meet his constituents and render some account of the stewardship they have entrusted to him.

Two very important resolutions have been carried by the Medical Council; and if we could believe that the Council had the determination necessary to carry out the resolutions to their legitimate results, we should be disposed to think that for once it had done something to justify its existence. Let us indulge in the pleasant hope that the Council will show an unwonted thoroughness in its work. It is not enough to spend the best part of a day in

Digitized by Google

passing even good resolutions. The only consequence of this is the expenditure of £100 or more over members' fees. What is wanted is effective investigation into the work which it is the main function of the Council to supervise. The resolutions referred to are as follows:—

"I. That in the opinion of the Council it is highly important to visit and report upon the methods of teaching required by the licensing bodies. II. That visitors be appointed by the General Medical Council to visit the several medical schools (with their permission) in each division of the kingdom, and to report upon their methods of teaching the subjects required by the licensing bodies, and upon the appliances possessed by them for such purpose."

It is not unimportant to notice that both resolutions were moved by Professor HAUGHTON. The first was seconded by Dr. MATTHEWS DUNCAN, the second by Dr. HERON WATSON. He would be a bold man who would venture to challenge the grammatical accuracy of anything proceeding from Dr. HAUGHTON, but we may question the practicability of "visiting the methods of teaching," which, by the first resolution, seems to be contemplated. The plain work to which the Council seems to be committed by the above resolutions is the visitation of the medical schools with a view to reporting on their efficiency as schools—that is to say, their mode of teaching, their plant, their apparatus, the proportion between the number of their pupils and their staff of teachers. It is probable that if this work is well done we shall have matter of much interest to the profession and to students. Nothing has been more obvious in all discussions of medical education, whether in the Medical Council or in Parliament, than the absence of any expression of interest in the state of the schools. The interest of the student is entirely lost sight of in the solicitude for the state of the Bodies. He may have no straw, but the tale of bricks must be delivered. The process of "ploughing" is come to be regarded as almost the normal thing in some Bodies, and the whole discredit is summarily heaped upon the unfortunate student. We have often tried to excite pity, or at least consideration, for him, but so far without much success. The Medical Council now proposes to examine the schools. Of course some members—over-cautious as to the functions of the Council, or fearful of the effect of criticism on their own schools—have endeavoured to shirk this obvious duty of the Council, or to show that it should devolve on the examining bodies. Fortunately they were in a minority, and we may hope that the Council of Medical Education will really acquaint itself with the state of the schools, and let us know how many of them have the appliances, the methods, and the teachers necessary to prepare students for the examining bodies.

Next in importance to a resolution to visit and report on the schools was the consideration by the Council of the reports of Visitors of examinations held in 1885. The examinations were those of all the universities, ten in number. The cost of this work was £2256 9*s.* 4*d.* The cost for each individual university was as follows:—Oxford, £163 16*s.*; Cambridge, £145 19*s.*; Durham, £124 19*s.*; London, £370 1*s.*; Edinburgh, £241 10*s.*; Glasgow, £285 12*s.*; Aberdeen, £137 11*s.*; St. Andrews, £168 3*s.*; Dublin University, £200 11*s.*; Royal University of Ireland, £252. Whether universities are higher bodies than corporations, or whether their examinations are higher or not, may be a question, though it certainly ought not to be a question. But it is noticeable that the cost of visiting the examinations of universities is just about double that of visiting the examinations of corporations. Roughly, the visitation of a corporation in 1881 and 1882 cost £100; that of a university in 1885 cost £200. The Visitors in the case of the universities were Dr. BALFOUR, Professor RAWDON MACNAMARA, Dr. LEISHMAN, Dr. FINNEY, Dr. BUCHANAN, Dr. KIDD, Dr. BRISTOWE, Mr. HOLDEN, and Dr. BARNES. Our readers will be interested in the reports of the discussion in the Council on the main points of these reports, so far as they have been threshed out by it. We confess to great disappointment in regard to the scope of the visit to the examinations of the universities, and we think the profession will have the same feeling. In the first place, the Visitors were limited to visiting the *final* examinations. In the second place, the Medical Council desired them to ascertain that "the courses of study and of examinations are such as to secure the possession by persons obtaining qualifications of the requisite knowledge and skill for the efficient practice of their profession." Surely nine less distinguished men would have sufficed to ascertain if the university examinations were sufficient as tests of mere competence for practice; and surely such men might have been asked to say whether the examinations were really higher—as the titles they carry are higher—than the final examinations of corporations. It is unfortunate for the universities that they are content with a mere certificate of being good *pass* bodies, and that the committee of the Council appointed to consider these reports finds them "decidedly favourable," because they show that the requirements of the universities are such as to secure an *adequate* knowledge for the practice of the profession, as if this were the object of a university degree. One of the liveliest afternoons in the session of the Council was that of Monday, when the critics of the London University were severe in their comments. It will be well for the friends and admirers of each university to study the discussion by the Council of the reports on the examinations of all the universities, and to draw their own conclusions.

ON Thursday, the 3rd inst., Dr. ALFRED CARPENTER delivered an address to the Croydon Farmers' Club, which was important for the nation as well as the district. It is well known that the sewage of Croydon flows by gravitation to the two sewage farms of Beddington and Norwood. The Beddington farm of 600 acres disposes of the sewage of 66,000 persons; it has been in operation for more than twenty years; it has never given rise to any nuisance or any disease in the neighbourhood; the land has risen from £1 to £9 per acre in value, and is still as capable of doing its work as it was when it was first used. This is a most important tribute to the value of sewage irrigation, and proves that the oft-repeated statement that land soon gets "sick" of sewage is, at any rate, not universally true. The whole address was full of matter for thought, and should be reprinted as one of the most valuable of the recent contributions to the solution of the hardest of sanitary problems.

Some years ago we reported on the two Croydon farms,

Digitized by Google

and we gather from the above address that they have undergone no important alteration since that time. There is a great natural fall to help the irrigation, and the sewage can easily be carried to the growing crop of rye-grass before putrefaction has advanced. This Dr. CARPENTER claims as a great advantage, as he has satisfied himself by experiments that rye-grass is almost carnivorous in its power of assimilating crude sewage. We are inclined to agree in this view, although the evidence adduced is scarcely conclusive. The sewage flows, or did flow at the time of our inspection, over the soil, and not through it, the system being correctly described as surface, as distinguished from downward, filtration. It is wonderful how effective, when properly managed, such filtration is in removing organic matter from sewage, and the long-continued success of the Croydon experiment seems to indicate that it is in some cases, if not in all, the best mode of working. The soil in the Norwood farm is stiff clay, and would be ill adapted for under-drainage, whereas, even in wet weather, a satisfactory effluent can be obtained from the surface.

Dr. CARPENTER insists with great sense on the necessity of making the sewage irrigation intermittent. There is no doubt that the occasional failure of what is certainly, when practicable, the best method of sewage disposal has often been due to the neglect of this precaution. Even Italian rye-grass, which, as the Rugby Commission long ago proved, is the only crop suited for the continuous assimilation of sewage, requires some time for the digestion of its food; and it is above all desirable that a week or more should elapse between the last application of sewage and the cutting of the grass. The economical disposal of the crops is a distinct and almost equally important question. The grass should be cut frequently before flowering; and the suggestion that a stock and dairy farm should be associated with the sewage farm is well worthy of consideration; it would probably pay in a good many places.

Altogether it would seem that at Croydon sewage farming has been a distinct success, which is certainly good news for the community. But, unfortunately, it is not every town that is as favourably situated as Croydon. London itself is the most remarkable example. Dr. CARPENTER argues with reason that the sewage should be applied to the soil before important putrefactive change has taken place. The nitrogen of the sewage, derived mainly from urine, is its most valuable constituent, and the researches of Dr. ANGUS SMITH have shown how easily this nitrogen may be returned in the free state to the air. But when it is urged that the sewage of London should be utilised in sewage irrigation, it is necessary to remember that the London sewage must necessarily travel a great way before it can reach the soil. Finally, when the throwing of the sewage into the sea is stigmatised as a ridiculous waste, the arguments of Sir J. B. LAWES as to the cultivation of the fish supply must not be left out of consideration. According to that distinguished authority, the sea-harvest derived from the discharge of sewage into an estuary may sometimes be more valuable than any possible land-harvest.

A BILL which bears the names of Drs. CAMERON and FARQUHARSON, of Sir GUYER HUNTER and Sir HENRY ROSCOE, is deserving of much consideration, but we are compelled to doubt if that which they have brought in for the improvement of dwelling-houses will be permitted to pass into law. The Bill proposes an advance in sanitary legislation much beyond its present position. Existing law does not give power to local authorities to inspect every house within their district, even if they are minded to undertake this duty. They can only claim rights of entry into houses already occupied where there is reasonable ground for believing that a nuisance exists upon the premises. There is no right on their part to inspect a house presumably in proper sanitary condition. But the Bill which is now introduced not only requires that every house shall be inspected, but imposes the expense incurred by such inspection upon the owner. Now every house not suspected of being in an insanitary condition is assumed to be in proper order. The Bill would reverse this position, so that every house not shown by professional certificate to be in proper sanitary condition would be deemed to be unfit for human habitation. We have no hesitation in saying that the passing of such measure would effect a very distinct gain in health in all districts for which it would become law, but the cost would be considerable, and could not be held to be final. Even assuming that a reasonably high standard of excellence were insisted upon by the surveyors upon whom the duty of examining and certifying were to devolve, it is obvious that the certificates which would be granted would not be of value for all time. Houses constructed with faulty foundations and indifferent material would within a short period have lapsed into defective condition, and the possession of a certificate for such structures would then be dangerously misleading unless it were of recent date. An examination of houses, to be of real value, must be periodic; and even then the value of the certificate as a guarantee of healthy conditions would depend largely upon the conscientiousness of the certifier and the method he adopted to test the drainage. A very different degree of excellence would be considered requisite by one surveyor to entitle a house to a certificate from that which would be required by another, and the provision which would enable so large a variety of persons to grant such certificates would lead, we are afraid, to the intentions of the supporters of the Bill being disappointed. Assuming for one moment that the house-owning interest in the Legislature could be induced to sanction a measure which would make considerable demands upon their resources, it would be very desirable that the duty of inspecting and certifying should devolve only upon those who might be trusted to insist upon a reasonably high standard of proficiency. We are afraid that among the great variety of professional men enumerated in the Bill there would be many who would not recognise as essential conditions which the educated health officer knows to have material effect upon the health of the inmates of a house. That such knowledge is wanting is especially shown in the metropolis, where it may be said that the construction of house drainage is fully a quarter of a century behind that of some other English towns. We believe there are few, if any, district authorities which insist upon the ventilation of house drainage; and, further, we think there are few, if any, such authorities that make the least reliable effort

Digitized by Google

to test the drainage after it has been laid and before the defects are hidden from sight. We have recently pointed out the full powers possessed by local authorities to insist upon the drainage of new houses being constructed in the form, and with the materials and workmanship, which they may require; yet apparatus is daily introduced into houses, and methods adopted, which offend against the most elementary laws of proper drain construction. The effects of passing such a Bill as that proposed would be considerable if a higher standard could be adopted than that recognised by local authorities as satisfactory; but some attempt at uniformity must be made in respect of this standard, and we must admit we see grave difficulties in the way of leaving this in the hands of every surveyor. On the other side, it must be recollected that the incompetency of local authorities has been amply shown, and it may not unfairly be argued that little good would come of the measure if it were left entirely for them to administer. We cannot now expect the Bill to come before Parliament this session, but we presume it will be introduced at a later date, when we hope the health requirements of the country will have a better chance of consideration.

Annotations.

"Ne quid nimis."

CANDIDATES FOR THE COUNCIL OF THE COLLEGE OF SURGEONS.

FOR the four vacancies there are eight candidates. Mr. Lund and Mr. Berkeley Hill are offering themselves for re-election. The other two vacancies are those caused by the death of Mr. Cooper Forster and the retirement of Mr. Allingham. There are, exclusive of the two gentlemen who seek re-election, six candidates, arranged in their order of seniority as follows:—Mr. Sibley (Fellowship 1857, Membership 1852), Mr. Couper (F. 1861, M. 1859), Mr. Willett (F. 1862, M. 1859), Mr. Rouse (F. 1863, M. 1851), Mr. Brudenell Carter (F. 1864, M. 1851), Mr. Reginald Harrison (F. 1866, M. 1859). Mr. Sibley's election, as representative of general practice, would be a decided gain to the Council. Moreover, as a business man there are few better Fellows on the College roll. The election of Mr. Couper would secure a sound Radical, and one in whose hands all questions of College reform would be quite safe. Mr. Willett, hailing from the largest of the metropolitan schools, where he is very popular, is sure of a good share of votes; while the active part he has taken in the proceedings of the Association of Fellows, and his well-known sympathy with the efforts which are now being made to secure certain reforms at the College, ought to secure for him the unanimous vote of that body. Mr. Rouse has not, in our judgment, any special claims on the electorate. Mr. Harrison must not feel disappointed if he prove unsuccessful in the presence of Mr. Couper and Mr. Willett, his seniors by some few years, especially while personal voting is still *de rigueur*.

SCIENTIFIC TEACHING AT THE MEDICAL SCHOOLS.

A NEW departure in the arrangements for the teaching of science in the medical schools has recently taken place by the transfer of those students who require a preliminary scientific course for the University of London from some of the London medical schools—viz., Charing-cross, Middlesex, St. George's, and Westminster—to the Normal School of Science at South Kensington. These schools will thus be relieved from the necessity of providing teachers in biology, physics, and advanced chemistry; and as botany is no longer insisted on as a compulsory course by the Conjoint Examining Board, these schools will now be almost entirely clinical, and not hampered with the task of having to provide an expensive scientific education for a very small class of students. The number of candidates at the University of London coming from these schools has always been small, and yet the machinery for a complete scientific training had to be found by each of them. We think that the school authorities are to be congratulated on this first step towards the consolidation of such teaching in London. It does not in the slightest degree interfere with the freedom of the other medical schools, and as the fees at South Kensington are not lower than those charged in the Faculties of Science at University and King's Colleges, it cannot be said to have introduced an unfair competition. A good course of scientific work under a single set of teachers has been substituted for what, we think, must often have been very unsatisfactory lectures and demonstrations at schools whose function and destination should be purely clinical.

THE MICROBES OF PNEUMONIA.

THE subject of acute pneumonia is one of those which of late has excited a considerable amount of attention, and yet, common as the disease is, it is one which is surrounded by many unsolved problems. Professor Weichselbaum has recently contributed to the Vienna Medical Society a paper, in which, after stating the prevalent opinions upon the nature of the affection, and dwelling especially upon the different opinions held by Friedländer on the one hand and Fränkel on the other as to the precise characters and properties of the supposed bacterial agent, he relates his own experiences. He points out that clinicians are divided into two camps upon the etiological question, some regarding pneumonia as solely an infective disorder, others considering that the infective forms are different from those caused by exposure to cold. Weichselbaum, distinguishing between primary and secondary forms, divides them into: (1) lobar; (2) disseminated; (3) passive pneumonia—hypostatic &c.,—and (4) lobular. He has examined 127 cases and instituted eighty-seven cultivation experiments, the material for the cultures being obtained one or two hours after death, as well as from the living subject, by means of a Pravaz syringe introduced into the lung and pleura. He distinguishes four kinds of micro-organisms. The diplococcus pneumoniæ is the most common, consisting of oval, elliptical, and round cocci, which occur in chains as well as in pairs. The chains are composed of from six to eight or as many as twenty to thirty cocci, are straight or slightly curved, and the cocci are enveloped in a capsule of varying thickness in proportion to their vitality. The second variety resembles the first, but distinguished by a greater uniformity in spherical shape, and in forming long and sinuous chains. The third is known as the Staphylococcus aureus s. albus. The fourth he terms the bacillus pneumoniæ, consisting of rods of different lengths, the smallest and apparently youngest being oval. They have a capsule, and correspond to Friedländer's pneumococcus. The first variety was found in ninety-one cases, mostly of croupous pneumonia, also in the secondary forms. The second, or streptococcus, was found twenty times—namely, in fifteen cases of primary and five of secondary pneumonia. The staphylococcus only occurred in secondary cases, and mostly where the primary disease was due to this micro-organism. The fourth kind was met with nine times, four times unmixed with other forms. All these organisms were most abundant in the earlier stages of the disease, being scanty or absent in grey hepatisation, and, if present, staining badly or unencapsuled. At the margins of the

Digitized by Google

pneumonic focus in the œdematous tissue micrococci were numerous, pointing to the œdema being not a passive process but a precursory stage of pneumonic infiltration, and resembling the invasion of cutaneous tissue in erysipelas. Moreover, inflammatory changes accompanied by these micro-organisms were found in the respiratory tract above the lungs. Secondary meningitis in pneumonia was shown to be due to the presence of the same micro-organisms, which were also found in the serous exudations of pleurisy and pericarditis, which might complicate the lung affection. The bacterial origin of the disease was therefore held to be demonstrated.

WHAT IS PRECOCITY?

THE question whether precocity is or is not a sign of disease ought to be prefaced by the inquiry, What is precocity? If we may venture to suggest an answer to this last query, it would be that precocity is really nothing more than early perhaps premature, use of the higher cerebral centres, particularly those which have for their function the more active processes of ideation, and therefore generally stand in near relation to the avenues of communication with the outer world—namely, the senses. In short, precocity nearly always shows itself in one or other of the arts, much less often the sciences. Even if the higher intellectual, and in a sense inner, centres are early energised, the excitation may be traced through channels which originate in the senses. For example, the calculating boy is a being gifted with a specially acute perception of sight or sound-phantoms, more commonly the former, which are so clearly apparent to his consciousness that he works out sums mentally with the ease of an expert using slate and pencil, and adds, subtracts, multiplies, &c., with the mechanical expertness of a bank clerk. In like manner the expert with sound-phantoms may compose music or make verses. There is, indeed, no reason why the higher centres should not be brought into play at any age after the completion of the first—or is it the second?—developmental period, somewhere about two years after birth. Of course there cannot be an instant packing of the brain with records of observation or experience, but there may be almost instant brain-work of the manipulative sort—if we may so call it—after independent life has commenced. This is the point to recognise.

THE ORIGIN OF MOUNTAINEERING.

SEA-BATHING, as we have already shown, owes its origin to an English physician; and no less true is it that another autumnal recreation—Alpine climbing—originated with a Swiss one. Classical antiquity lent no countenance to either practice. It is, indeed, a striking fact, noticed by M. Gaston Boissier in his "Promenades Archéologiques," that of all the Roman generals, many of them highly gifted, not one who crossed the Alps brought back any other impression than those of repulsion and horror from the passes, and snowfields, and peaks, "pinnacled dim in the intense inane," which attract modern tourists by the thousand. The sentiment of the sublime and beautiful in nature, thinks M. Boissier, arose in France with the "Confessions" of Jean Jacques Rousseau; but not to mention our English poet Gray, whose Alcaic ode on the 'Grande Chartreuse" is as un-Latin in inspiration as it is exquisitely Latin in rhythm and idiom, Milton and Addison on their classical tours have recorded impressions of the lovely and the grand in scenery unequalled by any of M. Boissier's compatriots. But before either of these, the palm of appreciation of the sublime and beautiful in nature rests with Conrad Gessner, the physician and scholar of Zurich, whose treatise "De Admiratione Montium," published in his twenty-sixth year, may be regarded as the embodiment of the Alpine tourist's creed. "So long as God keeps me alive," he says, "I am resolved to ascend one or more mountains every year at that season when the floral world is in full bloom, partly to extend my botanical studies, partly to invigorate my body and give my mind the noblest recreation. What pleasure, what ecstasy does it not yield the soul to gaze upon the giant mountain-masses and to turn one's eyes in wonder to the clouds! I know not how it is that one is rapt by the survey of soaring peaks and riveted in marvel at their Master Builder. Man was sent into the world to develop his admiration, to infer therefrom the existence of something greater, and so to rise to the conception of God Himself." Again, he asks, "Can there be within the bounds of Nature a more honourable, in all respects a more perfect kind of enjoyment?" For Conrad Gessner's mountaineering was of no vulgar kind. While denied the comforts and appliances of his latter-day successors, he was not content with merely clambering up to great altitudes. Many-sided *savant* as he was (the German Pliny was a title given him), he made these excursions subservient to science, particularly to botany; and it is to his familiarity with the mountaineers and their occupations that we owe his famous treatise, "De Lacte et Operibus Lactariis" ("On Milk and the Milk Industry"), published in 1541. The first, and to this day the best, narrative of an Alpine ascent is his "Descriptio Montis Fracti" ("Description of the Fracmünd," as Mont Pilate was then called). Nothing can be more picturesque than his account of the adventures he shared with his four *compagnons de voyage*: Huber, the physician of Lucerne; Boutin, the apothecary of Avignon; the sculptor, Petrus Figulus; and the painter, Johannes Thomas, the splendid illustrator of his botanical works. The energy that carried him over so many obstacles, physical and intellectual, wore itself out from sheer lack of rest, for when struck down at forty-nine by the plague, and feeling the approach of death, he rose from his couch, not to arrange his family concerns, but to put certain of his writings in such order that they might be ready for the printer, and thereby for the benefit of mankind. It was when so employed that he suddenly passed away, to the heavy loss of science, and of medical science in particular. His three books of "Epistles on Medicine," and his treatise on the "Mineral Waters of Germany and Switzerland," were but the earnest of what might have been achieved by his maturer life; while, such as they are, they were greatly in advance of the professional knowledge of their time, and amply merit for their author the niche he occupies in the gallery of medical worthies.

NITRO-GLYCERINE IN BRIGHT'S DISEASE.

THE employment of nitro-glycerine in chronic renal disease, for the valuable service it renders in dispelling or moderating uræmic symptoms, is based upon the fact that high arterial tension is the constant concomitant of uræmia. How far it is desirable to habitually employ a remedy having so pronounced an action upon the circulation as nitro-glycerine is yet undetermined; but experience of its value in the diseases which are marked by abnormal arterial tension is accumulating. The latest contribution is by Dr. Kinnicutt of New York (*Med. Record*, April 17th, 1886), who has studied the effects of the drug in several cases, with results which harmonise with those obtained by Rossbach and Burzbinski, to which allusion is made. The continued employment of the drug in slightly increasing quantity does not only relieve headache, dyspnœa, palpitation, and other symptoms referable to the uræmic state, but is marked by an increase in the diurnal excretion of urine, together with a notable diminution in the amount of albumen in it. Cases are given where the albumen was estimated quantitatively, and they show that in some the drug has a marked effect in its reduction. At the same time, as one case shows, there is often great variability in the albuminuria of chronic

Digitized by Google

nephritis, which renders it important that similar observations should be made on a large scale before trustworthy conclusions can be arrived at. The amount of nitroglycerine administered should be just within the limit of producing any subjective symptoms. Dr. Kinnicutt's conclusions may be given in his own words. "1. That in nitroglycerine, given in small doses and frequently repeated, we possess a powerful agent for lowering the increased blood-pressure which is very constantly associated with the development of uræmic symptoms. 2. That it has the power to control or relieve many of the paroxysmal disturbances of the nervous system which are included under the general term of uræmia; of these, headache and asthma are especially benefited by its use, the relief being more marked and continuous than that obtainable either by opium or chloral. 3. That its influence upon the daily excretion of urine and serum-albumen in parenchymatous and interstitial nephritis is apparently to increase the former and diminish the latter. 4. That in the systematic and prolonged use of nitro-glycerine in appropriate doses, in chronic nephritis, we possess a means of maintaining more or less continuously a lowered blood-pressure, of often averting or relieving critical conditions, and thereby prolonging life."

NOTES ON THE PARIS SANITARY EXHIBITION.

THE Paris Exhibition of Hygiene is now quite completed, and attracts a fair number of visitors. Nearly every day there are popular lectures, and members of the Society of Public Medicine and Professional Hygiene are constantly on the spot, ready to accompany small parties of visitors and give them the explanations necessary to render the exhibits intelligible to the uninitiated. The details concerning house drainage are what the French most require to know. The importance of the subject is not appreciated; but, as a first step in the right direction, French manufacturers have come to thoroughly understand the advantage of imitating English closets. Messrs. Rogier Mothes, who won the silver medal at the English Health Exhibition for their French closets, have now a number of closets on the English model which fulfil all the prescribed sanitary conditions. Messrs. Doulton and Co., on the other hand, imitate the French by providing a closet without a seat, which is best adapted for use in the poor quarters of foreign towns. The sides and flooring are all in strong enamelled hardware, which affords the best security for cleanliness. Some French closets have walls and floors of glass, and automatic flush tanks that cleanse not only the pan but the walls and floor. This is most advantageous in districts where the cleanliness of the inhabitants is not to be relied upon. The principle of a two-gallon flush is now fully accepted, though it will be difficult to persuade French householders to employ so much water for such a purpose. Where cesspools are used this is of course quite impossible, and there are not more than eighty houses in Paris that drain direct into the sewer. The tinnette filtre, however, by allowing the liquids to escape to the sewer, admits the introduction of an English closet, and these are applied to many of the better-class and newer houses. The principle of automatic flush tanks, both for house drains and public sewers, is also widely adopted. Large apparatus of this description are shown by the French as well as the English exhibitors. M. Aimond, notably, has a flush tank discharging at its lowest level, and therefore none of the force is lost by the necessity of drawing the water up and over a syphon placed below the reservoir. In sanitary engineering, Messrs. Genest and Herscher hold the first place. They display a disinfecting stove, where the best results are attained by the combined action of heat and steam under pressure. The highly scientific experiments which demonstrate the efficiency of this method will supply the subject of a separate study, and, for the moment, we can only call attention to what seems to be one of the safest disinfecting stoves constructed. The same firm have also an ingenious method for purifying cattle vans. A small boiler on wheels, which can be drawn along the platform of a railway station, supplies a hose enveloped in asbestos with superheated steam. This can be discharged against the sides of the cattle van, thus destroying all germs by damp heat. The ventilation and warming of houses, the diffusion of light within apartments, the methods for analysing air or filtering water, the culture of microbes, the attenuation of virus, and health statistics are all questions embraced in the general scope of the Exhibition. These and many other problems can be studied at the Caserne Lebau, where, we trust, the exhibitors will meet with ample reward at the hands of an appreciative public.

TUBERCLE BACILLI IN ADDISON'S DISEASE.

IT has long been held by some writers that the fibro-caseous change which characterises the suprarenal bodies in Addison's disease is of tubercular nature, and the histological characters upon which this opinion rests have been strengthened by the detection of the bacillus tuberculosis in the morbid material. For this observation pathology is indebted to Herr Goldenblum, of Dorpat, in a well-marked case of the disease which he examined in 1884. The subject was a man twenty-four years of age; there was well-marked bronzing of the skin and mucous membranes, caseation of both suprarenals, general wasting, pulmonary emphysema cloudy swelling of the heart fibres, liver, and kidneys, and swelling of the intestinal solitary glands and the portal lymphatic glands. At Professor Thoma's suggestion the diseased capsules were examined by Ehrlich's method, and large quantities of tubercle bacilli found in the caseous masses (Virchow's *Archiv*, Bd. 104, s. 393). Although Guttmann in 1885, and Rauschenbach in the present year, have reported cases of suprarenal bacillary tuberculosis, yet in neither case were symptoms of Addison's disease prominent, and both these cases must yield priority to Goldenblum's. He remarks that on the bacillary test his case goes to prove that in Addison's disease, in which the capsules are the only organs that exhibit caseation, the lesion must be regarded as a local tuberculosis, unless it can be proved that the occurrence of the bacilli is a secondary event.

INSANITARY VENICE.

WITH rather more than her proper share of the unhealthy conditions that seem inseparable from Mediterranean seaports, Venice has refrained from sanitary reform until three years of epidemic disease, with its consequent scaring off of visitors and of the advantages they bring, has aroused her to a sense of duty. Instead of reassuring proclamations by prefects or protests of injured hotel-keepers, it is edifying to read such a letter as that which Signor C. Castellani addresses to the Italian Government through the columns of the *Venezia*. "We must frankly confront the fact," he says in effect, "that Venice invites epidemic disease, and that Italy must interpose to save her most picturesque city from ruin. We must subject to the most vigilant surveillance the water-supply, the drainage, the canals, the dwellings of the poor, the food markets, the hospital service, the subsoil, the lagoons, the streets, the whole *ensemble* of Venetian life. Cleanliness, public and private, must be the order of the day, and until it is practically observed our economic kitchens and free dormitories do little more than parley with the enemy instead of expelling it. Money, however, is wanted, and the Italian nation must do for Venice what she has done on so grand a scale for Naples and other cities.

Digitized by Google

The Government which obtained from Parliament so many millions for Neapolitan rehabilitation, could it not spare a few for Venice, which has hitherto asked nothing? What Italian city has stronger claims on the national benevolence than the "pearl of the Adriatic"? Like her sisters of the seaboard, in fact, Venice is now the scene of something like an explosion of cholera, and having ignored the admonitions given her to stamp out the malady during its early insidious stage, she is making tardy amends for past remissness by an impassioned appeal for help from without. The Home Office, whom she now solicits for aid, warned her last winter to put no trust in quarantine, but to attack the disease when hibernating, so to speak, within her gates, and tread it out before its dimensions became unmanageable. Of course, the aid will be forthcoming, while the outlay it will exact from an already overtaxed country may prove a real economy if it disabuses Italy, once for all, of her faith in sanitary cordons, and converts her to the practice of sound hygiene, public and private.

HOSPITAL SUNDAY FUND AND THE THEATRES.

A *matinée* in aid of the Mansion House Hospital Sunday Fund will be given at the Gaiety Theatre on Wednesday, June 16th, under the patronage of the Lord Mayor and Sheriffs, who will be present on the occasion. The play to be represented is an adaptation of Sardou's "Vieux Garçons," entitled "Old Sinners," by Mr. J. Mortimer. It would be a graceful act on the part of London managers generally, if, at a time when a special effort is being made on behalf of the Fund, they would follow this excellent example, and each one of them devote the proceeds of a special "Hospital *Matinée*" to a form of charity which has relieved, and will continue to relieve, many members of their remarkably generous and charitable profession. Mrs. Langtry has also recently set a good example in a similar direction, and we are sure that managers will not be slow to take this hint.

THE ORIGIN OF THE BLOOD FROM A MEDICO-LEGAL POINT OF VIEW.

DR. MASSON, Pharmacien-Major in the French Army, has recently published an essay on the Origin of the Blood from a Medico-Legal Point of View. The difficulties attending this class of research are very great, and Dr. Masson has in his little work endeavoured to so far remove them that the expert may always be ready with a definite reply as to whether a blood stain was produced by the blood of a man or of an animal. After giving the different modes of procedure to ascertain this fact, the author states that the great cause of the alteration of fresh blood-corpuscles resides in the dampness of the medium or vehicle in which they are contained, the effect of which is to prevent the evaporation of the water of the plasma. In dried blood the corpuscle resists for a much longer time the causes of alteration; no liquid can regenerate the altered corpuscles. In the mensuration of the corpuscles by the microscope an approximation of one-fifth of a micro-millimetre may be obtained, but in reality a variation of this infinitesimal quantity does not admit of any differentiation. Moreover, in consequence of the great variability of the corpuscular dimensions in the same species in a physiological state (Hayem), and particularly in a pathological state (Kelsch found them augmented in volume in impaludism and Malassez in chlorosis; according to this last author the dimensions are reduced in cancer), a great number of mensurations must be made and an average struck. The following conclusions are arrived at after a course of experiments on dried blood operated upon with Virchow's solution:—The mean diameter of the hæmatics being superior to the $\frac{1}{130}$th part of a millimetre, the blood may belong to a man, a guinea-pig, a dog, or a rabbit; below the $\frac{1}{130}$th part of a millimetre the blood does not very probably belong to a man, but to one of the animals which, after him and the guinea-pig, possess the greatest number of corpuscles; below the $\frac{1}{130}$th part of a millimetre the blood does not certainly belong to a man.

THE VALUE OF SANITARY PROGRESS IN LIVERPOOL.

IN his annual report on the City of Liverpool Dr. Stopford Taylor gives some interesting information bearing on the gradual improvements which are there being effected in securing an improvement of the public health. We have recently adverted to some of these in connexion with the report of the city engineer on the sewers; and it is not less important to note the steps that are being taken to get rid of the bad house-property, which has for so long a time been one of the greatest evils which the Corporation have had to contend with. The "insanitary property" purchased in 1885 included 411 houses, and during the same period 631 houses were demolished. This may be taken as a type of the work which is steadily in progress; and Dr. Stopford Taylor points to the results of these and other labours by showing that whereas the average death-rate for the city was in the ten years 1841-50 as high as 36 per 1000, it has almost uniformly diminished during each subsequent period, until it now stands at 23·7 per 1000. He then goes on to point out that the application of the sanitary sciences to the improvement of public health is necessarily a work of an aggressive character, and hence, though its development is certain, yet the securing of its full advantages is a slow process. The aggressive action is also fully justified by the results obtained. Thus if during 1885 the same death-rate had prevailed as was in existence during the decennium 1851-60, the lives of no less than 3917 persons who were living at the end of last year would have been sacrificed. And, assuming that there are ten cases of sickness for each death, there was a saving of 39,170 cases of disease, with all the attendant cost of nursing, medical attendance, &c. And not only so, but every life has its value so far as the State is concerned. Taking a series of observations on the wages of the agricultural labourer, and making the necessary deductions for the mean value of his subsistence during the various periods of his life, the mean net value of life in that class at all ages and in both sexes is not less than £110 per individual; whereas amongst the population of all grades the value would amount to a net profit of £159 per head. Now, applying this estimate, which is that determined by the late Dr. Farr, to the 3917 persons whose lives were saved in Liverpool in 1885, there is a monetary saving of £622,803. And when to this is added the saving in the cost of sickness, funerals, loss of work, and increased pauperism, Dr. Stopford Taylor has the right to assume that there is enough to encourage the labours of the department over which he presides, and to inspire them with a hope of obtaining still greater benefits in the future.

BREAKING THE FACTORY ACT AT THE EAST-END.

ANOTHER meeting has been held at the East-end to protest against the "sweating system." Again a number of journeyman tailors came forward to testify that in their own workshops boys and girls, as well as adult males, were sometimes kept at work for sixteen and even seventeen hours a day. The victims of this system are too weak and too helpless to resist such oppression. Many of them even ignore that the law would protect them if it could only be set in motion. As this grievance continues we are compelled to repeat over and over again that the number of inspectors appointed to carry out the Factory Act is altogether insufficient. Mr.

Digitized by Google

Lakeman has accomplished his duty as inspector of factories in the East-end with much zeal and energy. Consequently he is thoroughly well known. There is a regular system of signalling established by which the "sweaters" are warned the moment the inspector approaches. They then have time to hide the young girls they employ in those parts of the house where the inspector has no legal right to claim admission. To cope with the evil a body of detectives is necessary. To rob a young helpless girl of her health by compelling her to work in an unwholesome overcrowded room for sixteen hours should be treated as any other criminal offence, and the full powers of the police engaged in its suppression. Short of this, one of the best means of defeating the stratagems employed by the "sweaters" would be to condemn the miserable tumble-down private houses where the worst of the "sweating work" is done. Public workshops, like public washhouses, should be organised. These could be properly ventilated, drained, controlled, and let out, like stalls in a market, to the jobbing tailors who at present work in their private and most unsuitable dwellings. Is it not possible to condemn rooms in private houses which have been converted into the workshops known as "sweaters' dens"? With the heat of summer approaching, and cholera still prevalent in Europe, this question is a matter that should not be neglected.

HOT BATHS, HOT PACKS, AND PILOCARPINE COMPARED.

DR. ZELENETSKI of St. Petersburg, in order to examine the comparative effects of hot baths, pilocarpine, and hot wet-sheet packing on nephritis, treated the same patients on different days by means of each of these methods, observing the effects on the temperature, pulse, &c. Fifty-seven observations were made on seven patients, who were as nearly as possible under identical conditions. Twenty-three baths, eighteen hypodermic injections of pilocarpine, and fifteen hot packs were given. The hot baths produced the greatest loss of weight, averaging 801 grammes, and the packing the least, averaging 94 grammes, pilocarpine producing effects of an intermediate character. Here the mean loss of weight was 514 grammes—306 by perspiration, and 208 by salivation. The temperature rose considerably after the baths, and even at the end of three hours was always above normal. The packing caused it to fall at first; but after an hour it rose, and returned to its original height within three hours. With pilocarpine it was reduced for two hours, and then rose to normal. The pulse corresponded to the temperature with the baths, but became slower with both packs and pilocarpine. The patients expressed themselves as feeling the most improvement after the baths; the pilocarpine causing complications, such as headache and nausea, and in one case vomiting and collapse.

REFORMS IN SPANISH MEDICAL STUDY.

SOME much-needed reforms are in contemplation by the Ministry of the Interior regarding the regulations affecting medical study in Spanish universities. Though no addition will be made to the duration of study, the course for the licence will be better arranged, so that preliminary subjects will be necessarily studied during the earlier portion of the student career—e.g., Histology, which at present is considered an advanced subject, is to be divided into Normal Histology for first-year's men, and Pathological Histology for third-year's men. Besides this, elementary clinical study will be included in Pathology, and a new subject—viz., the Diseases of Children—will be added. The Doctorate will consist of three subjects—the History of Medical Sciences, Chemical Analysis, and Public Hygiene, including the geographical and historical study of Epidemics. Probably also a voluntary additional subject will be permitted to be offered, such as Dermatology or Ophthalmology. Perhaps however, the most important reform of all is the arrangement for allowing students to take out hospital practice in provincial hospitals whose medical officers are willing to conform to certain regulations. It is to be hoped that, as *El Siglo Médico* says, there will now be an end of the sad spectacle so often seen of "wards empty of patients but full of students," and that the future practitioners of Spain will be better and more practically educated than those who have been hitherto sent forth to practise, many of them after a most inadequate clinical training.

PERMANGANATE OF POTASH IN AMENORRHŒA.

A RECENT number of the *Therapeutic Gazette* contains an able article on the value of permanganate of potash in the treatment of amenorrhœa. It appears that Dr. Fordyce Barker had long been incredulous as to the power of any article known to materia medica to act as a direct emmenagogue. He, in common with other physicians, has had ample experience of the use of iron, aloes, myrrh, savine, and rue, and had seen menstruation return apparently as a consequence of their administration, but he had never been convinced that this result was due to the direct influence of the drug on the uterus. For four years, however, he had used the permanganate of potassium exclusively when an emmenagogue was indicated, except in a limited class of cases of sudden suppression. Dr. Fordyce Barker, as the result of his experience, has never known the permanganate fail in any of the following groups of cases:—1. Girls between the ages of fourteen and nineteen, who come from the country to finish their education. Home sickness, entire change of their habits of life and associations, over-tax of their brain-power from their own or their teacher's ambition to accomplish more in a given time than they ought to attempt, not infrequently lead to an arrest of menstruation. 2. Patients, both young and married, who suffer severely from sea-sickness from leaving some European port within a few days of the menstrual period; with such amenorrhœa is almost sure to follow. 3. Patients between thirty and forty, generally married, some of whom have borne children, who rapidly begin to gain flesh, while at the same time menstruation decreases in both duration and quantity, until at last it is only a mere pretence. This is generally attended with annoying nerve disturbances, pelvic weight, piles, and often mental depression from the apprehension of growing old prematurely. In all these cases permanganate of potash is said to effect a speedy cure. These results have been in a great measure confirmed by Dr. W. H. Thomson, Dr. C. C. Lee, and Dr. Bellington, all of whom have used the drug since the appearance of the article by Drs. Ringer and Murrell in THE LANCET.

MODE OF PAYMENT OF FEES IN VIENNA.

IN Vienna it is usual to give medical men their fees at the end of the attendance, so that when honoraria are offered the hint is understood and no more visits are paid without further request. Some time since a practitioner was sent for to see the child of a certain tailor, whom he found suffering from fever, but with no signs enabling a diagnosis to be made. The fee was given, and the doctor hearing nothing further, did not consider his services were required again. However, it was discovered by the police, shortly afterwards, that some of the children in the tailor's house were suffering from small-pox. The tailor and the doctor were both summoned, the latter being acquitted, while the former, who was shown not only to have concealed the existence of the disease, but to have taken in work at the time, was sentenced to ten days' imprisonment.

SANITARY CONDITION OF THE ISTHMUS OF PANAMA.

SOME time ago Dr. A. Nicolas was sent by the Paris Public Works and Constructions Company to examine the hygienic conditions along the route of the Panama Canal, with a view to the organisation of an efficient medical service to combat the evils of which so much has been heard. His report, which confirms in many respects the unfavourable accounts previously published, was read before the Paris Academy of Medicine at the last meeting, and so much value was attached to it that the Academy decided to print it *in extenso*. The entire region through which the canal is to be cut is particularly insalubrious, the unhealthiness being at its maximum in the two towns of Colon and Panama, situated respectively at the opposite extremities. Panama, surrounded by marshy plains from which every breeze bears deleterious effluvia, is the more unhealthy of the two, and Dr. Nicolas considers that it would be useless to attempt to purify it—the town must be entirely rebuilt on another site if any good is to be done. Colon, on the other hand, is in process of rebuilding, after its recent destruction by insurgents; but it will be extremely difficult to improve its sanitary character unless a lagoon which penetrates to the heart of the town is destroyed. The temperature on the isthmus is not extraordinarily high, but the hygrometric condition of the air is peculiar, being always near the saturation point from 7 A.M. until 7 P.M., and the whole region is covered with mist, which prevents radiation, and probably modifies the electric condition of both air and soil. The heat on the isthmus has peculiarities not met with either in Mexico, on the Congo, on the Gaboon, or in Guiana; but it is not without analogy to that of the Tonquin delta. The enervation which it produces is characterised by loss of memory, persistent sleeplessness, and peculiarly passive and profuse perspiration. Dr. Nicolas concludes his report with various recommendations with a view to diminishing the mortality, amongst which drainage and attention to the water-supply naturally occupy a prominent place. It is evident that sanitary conditions are not by any means the least of the difficulties which M. de Lesseps and his colleagues have to contend against in carrying out the gigantic work they have undertaken.

SEGMENTAL NEURITIS.

THERE appear to be good grounds for the division of neuritis into "interstitial" and "parenchymatous" varieties. The latter form has many causes, but the pathological anatomy, consisting in a series of modifications ending in atrophy of the nerve, presents but little variety in its characters, and has a close resemblance to the series of changes such as occur in the Wallerian degeneration of divided nerves. Apart from this form there is another, described first by Gombault, under the name of "névrite segmentaire periaxile." Guinea-pigs submitted to a process of slow poisoning by lead, without presenting any sign of localised or diffuse paralysis, yet became the subjects of a scattered neuritis of such a kind that one part of the length of a nerve fibre was inflamed, whilst the parts above and below it were in a normal condition; these disseminated patches sometimes occurred in more places than one on the same nerve fibre. Generally the alteration involves a single nerve segment, but it may transcend these limits or even be restricted to a portion of one segment. The process is of a genuine parenchymatous character, but affects only the myelin sheath and the protoplasm of the sheath, not the axis cylinder, which is never interrupted, and remains in relation with its centres; the nuclei multiply and the myelin undergoes segmentation. This form of neuritis is not special to guinea-pigs or to cases of chronic saturnism. It occurs also in man, and Gombault has observed it in the subjects of protopathic muscular atrophy, amyotrophic lateral sclerosis, and traumatic neuritis. He has also described it in a case of diphtheritic palsy, and in one which clinically resembled acute ascending paralysis. However, this periaxial segmental neuritis has not been frequently observed in further researches on the pathological anatomy of peripheral nerves, and since 1880 P. Meyer alone has given a description of its existence in a case of diphtheritic paralysis. In the *Archives de Neurologie*, No. 33, MM. Pitres and Vaillard—already well known for their researches, especially on parenchymatous neuritis—have described an interesting case of pulmonary tuberculosis on which cutaneous diphtheria became grafted, and was followed by amblyopia, paralysis of the soft palate and limbs, with disorders of sensation, paresis of the diaphragm, irregularity of the heart's action, and death from pulmonary hæmorrhage; the brain and spinal cord were found to be healthy, but the peripheral nerves and spinal roots exhibited the changes indicative of the segmental form of neuritis. It has been shown by the same observers that peripheral neuritis occurs in tuberculosis, and they discuss the question of the dependence of the changes spoken of above on diphtheria or tuberculosis. For fuller information reference should be made to the valuable paper, which is illustrated by well-executed plates.

CONVICTION UNDER THE POISONS ACT.

A TRADESMAN has been fined twenty shillings with costs for unlawfully selling an ounce of cyanide of potassium, contrary to the provisions of the Pharmacy Act of 1868. The Act requires that the person to whom any poison is supplied should be known to the seller, or should be introduced by someone known to him. It is also necessary that the name and address of the purchaser should be entered in a book kept for the purpose, with the name and quantity of the poison sold, and the object for which it is stated to be required. From the evidence it appeared that the drug was sold in the photographic department of the establishment, that no questions were asked by the assistant, and that no entry was made in any book. For the defence it was urged that the manager of the department had come with excellent credentials from large and well-known London firms, but was unfortunately ignorant of the requirements of the Act of Parliament. Mr. Cook, in giving his decision, said that cyanide of potassium was a most deadly poison, and when sold, even to photographers, it should be under strict supervision. In his opinion the present restrictions were very mild indeed. The prosecution was not vindictive, for the poison was being sold just in the same way as would be a yard of ribbon. With this expression of opinion we concur.

RICE-THROWING AT WEDDINGS.

THOSE who assist in a wedding ceremony may usually be excused if they forget that, even at such a time, there are bounds to merriment; but the sport may sometimes be too serious for excuse, as in an instance lately reported. A bridal couple were leaving the Church of St. James-the-Less, Bethnal Green, and, according to custom, were greeted with a liberal shower of rice. The bride, fortunately, found her veil a sufficient protection, but the bridegroom's eyes have suffered so severely that he is now under treatment in a hospital ward. The practice of pelting with rice, we are given to understand, is even more prevalent at St. James's than elsewhere, from the frequency of marriages among the poor of the parish; and it is said that the accident above described is no singular example. Without at all wishing to mar the good humour of such occasions, we would point to the obvious moral of this occurrence. We should like to know

Digitized by Google

why and by whom this use of rice at weddings was introduced. It seems to us, and has doubtless often before this appeared to others, to be a singularly inconvenient and uncomfortable means of practical raillery. Perhaps economy has found other uses for the old slippers which followed the retreating steps of our parents and grandparents. Perhaps, also, a careless hand might do some damage, even with these time-honoured symbols. Anyhow, it must be owned that the rice-throwing custom is more than a harmless pastime. Inflammation induced in an eye by such an accident might easily lead to grave mischief before it could be checked—might result in permanent weakness of the organ or even in loss of vision. These facts we venture to press upon public consideration.

THE CHOLERA IN ITALY.

THE news as to cholera in Europe is still confined to Italy, and even from that country it is very intermittent. But, putting together the intelligence which reaches us from several sources, it is evident that the disease is still very fatally prevalent in Venice and at Bari. Since cholera was first officially announced to have caused deaths in Venice at the beginning of May, the fatal attacks have amounted to 266 in number; and during the past week they have ranged from 10 to 26 a day. This condition of things shows that the disease has a firm hold on the city, and if the circumstances which are usually favourable to an epidemic should supervene this season, it is to be feared that Venice will suffer heavily. As regards Bari, the news is not so serious; but there is still a steady continuance of cases and deaths, and few days, if any, pass without one or more fatal attacks. The disease has now prevailed in Bari ever since the end of the first week in May, and 78 fatal attacks have already occurred there. The outbreak was most severe during the second week of May; but although it diminished in intensity as the month progressed, that diminution has not been sustained, and a sufficient number of fatal attacks still occur to show that the disease is maintaining itself with some tenacity in the place. No further news of a trustworthy character as to the disease in other parts of Italy is forthcoming.

APPARENT INTOXICATION.

THERE is reason to fear that mistakes are not unfrequently made, even by skilled observers, in the recognition of drunkenness, by what may be called "apparent intoxication." The unsteady gait, the congested face and neck, the vacant eye, with drooping lid, and even the spirituous breath of apparent intoxication, may one and all be the effects of disease or disturbance of function, which has no necessary connexion with the abuse of alcohol in any form. A melancholy instance of blundering in respect to this matter may be cited from the life of the late Colonel Herbinger, who, as our Paris correspondent mentioned last week, was accused of intemperance during his field service at Tonquin, but happily acquitted. Professor Peter, who had opportunities of studying the case of this recently deceased officer shortly before his death, elicited that he was suffering from a malady of some years' standing, which produced cerebral anæmia with such giddiness that he could scarcely sit on his horse. Similar cases are by no means uncommon, and while it is more than ever necessary to denounce the practice of permitting police officers to determine whether a man or woman is drunk or the victim of disease, it is requisite to go much further than this, and to call the special attention of skilled practitioners in medicine to the possibility of being mistaken by erroneous impressions on this subject. Not only will anæmia of the brain, however induced, cause giddiness, but certain forms of defective assimilation will bring about the same results, together with symptoms still more deceptive. We need to study more closely the effects of an excess of oxalic acid in the blood, of accumulated uric acid, or urate of ammonium, of acetone, &c. Something has been done in this direction; but, so far as we are aware, the precise cause of a peculiarly offensive odour of the breath expelled from the mouth, seemingly distinctly alcoholic, has not been satisfactorily made out, although several good clinical observers with a fair knowledge of the chemistry of digestion and elimination have undertaken to solve the problem. It would be useful to investigate the subject further; more light is desirable, and even necessary.

SUGAR AND CORROSIVE SUBLIMATE AS A FIRST DRESSING IN WAR.

DR. HEIDENREICH, in a paper published in the *Vrach* (Nos. 19 and 20), strongly recommends as a first dressing on the field of battle a mixture of corrosive sublimate with powdered sugar in the proportion of 1 to 1000. It is important that when this is prepared the sublimate should be evenly distributed, and this is easily effected by first dissolving the mercurial salt in a little spirit and then carefully rubbing up the sugar with it. The spirit ultimately evaporates and leaves a powdered mass of uniform composition. A little packet is supplied to each soldier, containing a capsule in which is five grammes of the mixed powder—i.e., $\frac{2}{100}$ of a gramme of sublimate—for the purpose of sprinkling on the wound; also a good-sized piece of gauze impregnated with $\frac{1}{4}$ per cent. of its own weight of sublimate by means of Bergmann's process, which consists of dipping it in a solution containing 10 parts sublimate to 500 glycerine 1000 alcohol, and 1500 water. Some hygroscopic wadding is also supplied, and this, when enclosed between two folds of the gauze, forms a dressing measuring 650 sq. centim., which is large enough to cover a somewhat extensive wound. The whole is enclosed by means of a layer of varnished paper and a triangular bandage, which is fastened with two safety pins. The author claims for this mixtnre of sugar and sublimate the advantage of being a particularly powerful antiseptic and quite innocuous. Sugar, he says, is the best substance for diluting the sublimate, being itself somewhat antiseptic. This dressing has also the additional advantage of being suitable for use wherever water may be procurable. This, of course, is not always the case, and where it is the source is frequently in a marsh or pool of anything but hygienic appearance. Under these circumstances he advises that filtration should be resorted to, and consequently proposes that a kind of filter consisting of flannel impregnated with sublimate should be included in the packets supplied to the men. The whole contents of the packet weigh only seventy-five grammes, and are exceedingly portable and inexpensive.

A CHEMIST CENSURED FOR MEDICAL PRACTICE.

A CHEMIST in Harpurhey, near Manchester, has been censured by a jury for attending a man for a fortnight with hæmorrhage from the nose and mouth, a subject of the hæmorrhagic diathesis. Matters were made worse by the extraction of a tooth, though the report does not say that the tooth was drawn by the chemist. The hæmorrhage persisting, and he thinking that no local doctor would consult with him since his last "unpleasantness"—he has been repeatedly cautioned or censured in regard to similar conduct before,—he called in a young qualified man. Thereafter the chemist resumed his attendance. But the bleeding recurring, Mr. Armstrong was called in—only, however, to find the patient hopelessly bloodless.

Digitized by Google

died in a few days, and Dr. Harris, pathologist of the Royal Infirmary, found very little blood left in the body, and hæmorrhage into both pleural cavities. Mr. Wilkinson, Mr. Armstrong's partner, thought that proper treatment might have saved the case. Mr. Jackson seems one of those bold chemists who are not affected by the death of patients or the censure of juries. But it is truly lamentable to see a man's life squandered away without proper help, and a respectable chemist a party to the tragedy. Young members of the profession should not put themselves into such an undignified and unsatisfactory position as that of covering or protecting a chemist in medical practice in the gravest of cases.

THE MEDICAL BILL.

"HOPE springs eternal in the human breast." Sir Lyon Playfair still has hope of being able to pass his Medical Bill. We confess to being less sanguine. But nothing seems to happen now in politics but the unlikely. We look to him to concede the greatest possible representation of the profession and the perfect independence of the Medical Council from pressure by the Privy Council in the matter of recognising foreign degrees. And we look to Dr. Foster to help Sir Lyon to be faithful in these respects. No meeting of the Medical Council more than the present one has exhibited the faulty constitution of this body. Its discussions are marred by the obvious jealousy of rival bodies and the absence of independent members. And the highest examinations are only treated by the Council as guarantees of competence.

M. PASTEUR'S PATIENTS.

THE last fatal case under M. Pasteur's treatment appears to have been peculiar, and can hardly be placed in the balance against his method of prevention. It is true that the patient came under treatment fourteen days after the infliction of the wounds. But the wounds themselves made about the head, which were of an unusually severe nature, may fairly be regarded as possibly of a fatal character in themselves apart from the introduction of the virus of rabies. The maniacal symptoms that the man presented were certainly out of the run of ordinary cases of hydrophobia, and the post-mortem examination appears to have revealed alterations in the lungs not ordinarily met with after death from that disease.

ALCOHOL IN HOSPITALS.

THE *Irish Temperance League Journal* is perplexed by the diversity of practice as regards the amount of alcohol used in hospitals. If it be admitted that the question of its use is a scientific one, our contemporary claims that there should be some approach to uniformity. He cannot understand why London hospitals should cost for alcohol 4*s.* 8½*d.* per patient while 2*s.* 5½*d.* suffices in the country. Does the same difference hold of the doses of opium, digitalis, and other *drugs?* This is rather a superficial question, ignoring the dietetic use by the people of some alcohol. It is more reasonable to be embarrassed by the different practice of hospitals in the metropolis; so that while, for example, University College Hospital spends only 2*s.* 7*d.* per patient on alcohol, St. George's spends 4*s.* 9*d.* Perhaps a still greater difficulty, on the scientific theory, is the difference in practice between physicians of the same hospital. We demand for our professional brethren full liberty of action in regard to this question, but we would remind them of the gravity of it. It is grave in this sense, that if a man goes into a hospital and is plied with stimulants by eminent physicians, he is very apt to continue the treatment himself when he comes out. Another point made by critics is the impossibility of apportioning the expenditure on stimulants to officials and patients. The secretary of the Middlesex Hospital has calculated that 66 per cent. of the expenditure on alcohol is for its consumption by officials.

SIR WILLIAM GULL.

OUR readers will note with regret that Sir William Gull was unable to take his seat in the Council as the representative of the University of London. We are glad to be able to say that Sir William is not absolutely confined to his room, and is improving.

THE FIRST RUSSIAN PROFESSOR OF PSYCHIATRY.

THE death is announced in Moscow of Dr. Grigori Sokolski, formerly Professor of Therapeutics and Psychiatry there. He was a contemporary of Pirogoff, and, like him, when he had completed his obligatory medical course, went to Dorpat to attend the "Professoren Institut." After that he spent two years in Berlin and Vienna, and subsequently was appointed to professorships in his own country, first at Kazan and afterwards at Moscow. He was the first professor who lectured on mental diseases in Russia. He resigned in 1848, since which time he has been living in complete seclusion from the outer world. He was in his eightieth year.

QUINTUPLE BIRTH.

Il Morgagni (May 29th) mentions the following case recorded by Polyakoff in the *Meditsinskæ Obozpénye*, No. 10, 1885. A robust peasant, aged twenty-seven, of Syarai, Russia, after nine years' married life, became pregnant for the seventh time in June. In the latter period of pregnancy the abdomen assumed vast proportions, and on the 1st of March the woman gave birth to five female fœtuses at short intervals; three presented by the occiput, two by the feet. Each had a sac with separate amnion, but the chorion was common to all. The first fœtus was deformed and stillborn; the others lived some minutes after birth. The single placenta weighed a pound and a half, and the umbilical cords were attached to its extremity. Four of the fœtuses were well formed; but the first born was microcephalic, and had not the full number of fingers or toes. The umbilical cord attached to this fœtus had an artery and a vein, but each of the others had three vessels.

INFANTICIDE BY PERAMBULATORS.

DR. MACLAGAN, the medical officer of the Hexham Rural Sanitary District, while calling attention to the fact that in his district 124 children out of 1000 die during their first year, attributes much of the mortality to "inflammatory diseases, cerebral and pulmonary," caused by exposure in perambulators. This is a startling but not, we fear, unreasonable opinion. There cannot be any question that young children are placed at a very great disadvantage as regards the risks attendant on exposure when they are lying inactive in a vehicle of this description, either in the sun or pushed against the wind. The old-fashioned child's cart, which was drawn behind the nurse, was open to the objection that the child might be taken out, and a weight substituted, the nurse being unaware of her loss. Those who read the newspapers forty years ago will remember several cases of this class in which infants were purloined in the manner indicated. The perambulator, or *pre*ambulator as it used to be called, being pushed before the nurse, has not this disadvantage; but it certainly exposes the child severely to the wind-pressure, and, if Dr. Taylor of Scarborough is right, as we believe he is, in laying much stress on the matter of wind-

Digitized by Google

pressure in reference to the causation of throat and chest complaints, it is well worth considering whether Dr. Maclagan is not justified in the assertion that "the use of perambulators should be strongly condemned." The matter is clearly one that deserves attention.

AT the Clerkenwell County Court on the 4th inst., an action was brought against Mr. H. D'Arcy Power, a medical practitioner residing at Peckham, for misrepresentation and malpraxis. It was alleged that by the improper use of instruments he had caused a miscarriage which resulted in serious illness After a protracted hearing and an exhaustive summing up, the jury returned a verdict for the defendant, and judgment was entered in his favour, with costs on the highest scale.

UNDER the title "Il Clima di Roma: Conferenze fatte nella Primavera del 1885," Dr. Tommasi-Crudeli has published a revised version of the eight lectures with which he inaugurated the Institute of Experimental Hygiene in the University of Rome in the spring of last year. The volume is accompanied by a new and carefully executed topographical and geological map of the Agro Romano, and by five illustrative charts. The publishers are Lœscher and Co.

DR. CROOKSHANK has in preparation a new work illustrating the value of photography in delineating preparations of bacteria. The work will be illustrated with upwards of fifty permanent autotypes and numerous wood engravings. The negatives have been for some time in the hands of the Autotype Company, and are being produced in special colours under the supervision of the author. The work will be published by Mr. H. K. Lewis.

BY the lamented death of Professor Auspitz, the chair of Dermatology and Syphilis has been rendered vacant. His place in the editorship of the "Archiv für Dermatologie und Syphilis" will be taken by Professor Kaposi, in conjunction with the former co-editor, Professor Pick of Prague.

A BACTERIOLOGICAL department will be opened in connexion with the Pathological Institute at Berlin, presided over by Professor Virchow. It is probable that Dr. Israel will be nominated director of the department.

DR. JOSEPH RODIER, of Montreal, is, we understand accredited by the Provincial Government of Quebec on a mission to Paris to gain an insight into M. Pasteur's method of inoculation as a preventive of hydrophobia.

IT is understood that Dr. Oliver Wendell Holmes will be one of the recipients of the honorary degree of Doctor of Civil Law at the forthcoming Commemoration at Oxford.

THE late Professor Haeser, whose work on the History of Medicine is classical, bequeathed his valuable library to the Breslau University.

PROFESSOR WEIL, of Heidelberg, has been invited to fill the office of Director of the Medical Clinic at Dorpat.

His Royal Highness the Prince of Wales has consented to open at an early date the new out-patient department and nursing home attached to the Victoria Hospital for Children, Queen's-road, Chelsea, the foundation-stone of which was laid on June 23rd, 1885, by Her Royal Highness the Princess Louise, Marchioness of Lorne.

DR. RICHARDSON'S LECTURES ON ANIMAL OR VITAL MECHANICS.

LECTURE IV.

MECHANICS OF THE CIRCULATION.

IN the fourth lecture of the course the subject of the Mechanics of the Circulation was chosen as one which permitted of richest illustration of mechanical plans and workings from Nature as the designer and worker. The tube, the valve, the elastic structures, the contractile structures, the pump, the river, the surface, would all come under observation, and to the mere mechanical instruments would be added the details of the work done as the result of the mechanical skill and operation.

The description of the circulating apparatus was commenced from the venous side of the circulation. A fine drawing, of life size, from Vesalius, was projected on the screen in order to illustrate the entire venous system as in a transparency. The faithfulness of this work of the great anatomist was wonderfully exhibited in this figure, and was followed by another in which the main trunks of the veins were indicated as the receiving trunks of what Dr. Richardson designated the true river of life. The circulation of blood, in its primary movement, begins, he contended, in the veins, in a venous current which does not depend in the first instance on the stroke of the heart, but which has its origin in the digestive tract, and which supplies the heart, as from a vast surface of absorption with fluid, from food and drink, and from the lymph formed in the drainage surface of the body. The great venous channels, the rivers of life, thus supplied, run, guided by the valvular arrangements, into the right side of the heart and form the primary force of the circulation. The rivers charged, the right auricle of the heart needs but a moderate pumping power to deliver the blood it receives to the right ventricle for distribution to the lungs, and, by comparatively easy stroke over the lesser or pulmonic circuit, to the left auricle, and so on to the left ventricle for arterial pulsating circulation. The part which pulsation plays in the arterial system was made matter of comment, in which it was suggested that the pulsating motion is necessary for all secreting, excreting, and nutritive functions, since by it a period of rest from propulsion is secured after each systole, during which period of rest the required changes can be carried out. Quicken the pulsations until the current is exalted into an almost continuous course, as in fever, and then with the generation of heat there is reduced secretion, excretion, and nutrition. Reduce the pulsation, so as to leave long periods between each stroke, and then with a reduction of temperature there is obstruction, accumulation, and impaired restoration of function. From this description of the course of the circulation the lecturer passed to that minute circulation of the blood, in the capillary system, in which the chemical part of the vital actions is carried out. From two of Rudinger's photographic plates of dissected structures he showed the centres of the nerves of organic life, and having indicated how these and their ramifications differ from the centres and nerves of the cerebro-spinal system, he traced the organic nerves through their distribution along the course of the arteries to the capillaries, and explained how, by their controlling influence, the supply of blood to different organs is modified. The influence of emotion, through the organic nervous system, upon the vascular system, and upon the colour of some parts of the body, such as the cheeks, was indicated in the acts of blushing and the paling of the cheeks under excitements from joy, surprise, or fear—an exposition which led to an original suggestion by Dr. Richardson, that the absorption of the vibration incident to arterial pulsation is probably effected by and through this nervous arrangement. The picture of the arterial system as a whole, from Vesalius, was thrown on the screen, and the mechanism of the arterial tubes was shown, as in transparency, of life-size. This vast series of tubes from root to minute branch up to the commencement of the capillary tubes is all through life, in waking and in sleeping, in one continued swing of balancing pulsation; and yet in health we are unaware, by any sensation of so strange a fact, and of the part which the central heart, or pump, itself plays in it. There must therefore be an absorption of the vibration some-

Digitized by Google

where, and the lecturer thought it most probable that this was by and through the organic nervous fibres. The vibrations are conducted back to the nervous centres, and transmitted from them to other organic parts to be disposed of in work, physical and mental. So when the heart is beating very strongly we feel the reflex back into the great ganglionic centres of the stomach in sensations varying from a pleasant glow to spasm or acute pain. The lecture was brought to a close by a demonstration of the action of the valves of the veins and heart and of their respective parts in directing the currents of the blood.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE fifty-sixth annual meeting of this Association, appointed to be held in Birmingham from Sept. 1st to the 9th inclusive, promises to be one of the most brilliant and largely attended scientific congresses ever assembled. The President is Sir William Dawson, C.M.G., F.R.S.; and amongst the chief officers of sections are—Professor G. H. Darwin, M.A., F.R.S.; Mr. W. Crookes, F.C.S., F.R.S.; Professor T. G. Bonney, D.Sc., F.R.S; and others equally distinguished. The Biological work of the Association continues to grow in importance, and the comparatively new section of Anthropology cannot fail this year to present many features of exceptional interest for the medical profession, under the joint secretaryship of Dr. Garson and Dr. Robert Saundby.

The many distinguished Canadian as well as European men of science who are expected at the Congress may rely on hospitable welcome to the homes of the most prominent inhabitants of the midland metropolis, the central position of which may be made the best use of by all visitors, through the exceptional facilities which the converging railway companies are offering. The educational institutions which adjoin the Birmingham Town Hall and Council House have been placed at the disposal of the Association; and members and associates are assured of free access to the numerous local literary and scientific institutions and social clubs. For the archæologist, the botanist, and the geologist Midland England is a rich field; and with such guides as Mr. Sam. Timmins and Professor Lapworth, Mr. W. B. Hughes, F.L.S., and Mr. William Mathews, M.A., visitors cannot fail to gather an abundant harvest.

Birmingham justly prides itself on having projected the movement out of which the School Board system has been evolved, and no one could have been deputed to set forth the educational resources of the town more ably and worthily than Mr. Osmund Airy, M.A. The best opinions are equally concordant on the choice of Mr. Thackray Bunce, the Birmingham historian, to present a report on local governing bodies.

A special sub-committee, of which Mr. Councillor Lawley Parker is chairman, is organising an extensive exhibition of the products of local industries and of local manufacturing processes. This exhibition will be, in some respects, unique, since it will be exclusively confined to exhibitors whose manufactories are situated within a range of fifteen miles from Birmingham, and will thus represent the special characteristics of the industries of the town and district. A collection of the Flora and Fauna, together with the rocks and fossils of the neighbourhood, will be shown in connexion with the exhibition. The Mayor will invite members and associates to a conversazione in the Council House; and on Wednesday, September 1st, Mendelssohn's "Elijah," which was first produced at the Birmingham Festival of 1846, will be performed in the Town Hall with a full band and the renowned chorus of the Birmingham Festivals. Many able and zealous persons will have to be credited with a large share of merit for having taken part in the scheme of which we have briefly traced the outline; but it is quite safe to say at once that success was practically assured when the following gentlemen were chosen the leading officials of the executive:—Alderman Martineau, the Mayor, chairman; Mr. J. D. Goodman, honorary treasurer; the Rev. Dr. Crosskey, Mr. J. Barham Carslake, and Mr. Councillor C. J. Hart, honorary secretaries.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Basford Rural District.—Dr. Boobbyer in reporting on this district shows how the vital statistics for certain divisions bear out the view, originally expressed by Dr. Buchanan, as to the influence of damp and low-lying sites on the mortality from phthisis. The general death-rate for the whole district in 1885 was 15·0 per 1000, and that for the so-called zymotic diseases 2·48 per 1000, scarlet fever and diarrhœa being mainly responsible for the latter. In the course of the systematic inspections which have been made, numerous instances of overcrowding, improper dwelling accommodation, bad water-supply, &c., have been dealt with; but the extensive parish of Selston is referred to as still notoriously ill-supplied with drinking-water. As regards drainage, it is stated that new systems are to be provided for Codnor, Nuncar Gate, and West Bridgeford. Scarlet fever has been very rife in some parts of the district, and an opinion is expressed in the report to the effect that the decomposition of simple organic matter, in certain states of health and especially amongst infants, is capable of playing a very important part in the autogenesis of the disease. Efficient means of isolation and disinfection not being available, but little could be done by a medical officer of health in the direction of the proper control of this disease.

Glanford Brigg Rural District.—The mortality for this district on a population of nearly 30,000 was at the rate of 15·5 per 1000 for 1885, this rate being the smallest registered for many years past. No single death from small-pox has been recorded in any of Mr. Moxon's reports, and it is satisfactory to notice that 98 per cent. of the births are accounted for as regards vaccination. There has also for some time past been an absence of any fatality from scarlet fever, but as there are no trustworthy means by which to protect a population against the risk of this infection if once exposed to it, Mr. Moxon wisely reminds his authority that hundreds of children have been growing up who may at any time be infected, and that it behoves them to be ready in advance to apply measures of isolation and disinfection. Diphtheria, unfortunately, was rife in the district, causing twenty-one deaths during the year, in addition to four from so-called "croup." In some parts of the district urban powers are much needed to secure control under bye-laws as to the stability and wholesomeness of dwelling-houses. These should be applied for to the Local Government Board, who never offer objection where a need for them really exists. Some substantial progress has been made in the matter of the water-supply and drainage of several villages, and systematic inspection of the district has been carried out.

Buxton Urban District.—Sanitary progress is stated to be continuously maintained year by year in this district. During 1885 the sewage works were brought into permanent operation; the process being one of precipitation, after which the effluent passes into the river in a state which is declared to be within the limits of impurity allowed by the River Commissioners. The residual sludge is now to be manufactured into a manure. The water-supply, though wholesome, is at times muddy, and, pending improved means of storage, the population are advised to resort to domestic filtration. The annual death-rate for 1885 was low—namely, 9·09 per 1000 on a population of 6707; but this does not take account of deaths amongst visitors, who, to the number of 100,000, visit the place annually. It is also satisfactory to note that the deaths due to zymotic diseases were fewer in number than during any year in the previous decade.

Romford Rural District.—In a tabular form a good deal of information is given as to the proceedings taken on the occurrence of infectious diseases. In the case of small-pox the sanitary authority evidently trust to the chance of there being available accommodation at Highgate Hospital, but this sometimes fails, and then the cases become centres from which the disease spreads. So also as regards scarlet fever, which occurred in several parts of the district, the need for a local isolation hospital has been much felt. Some parts of the rural area still call for many remedial measures. At Dagenham and other neighbouring places, foul privies, lack of decent meansof drainage, and similar defects,

Digitized by Google

bring about conditions which are dangerous to health, but fortunately wells containing polluted water-supplies have been done away with. This is a scattered district containing a population exceeding 22,000, and the careful records of its sanitary state show how much it stands in need of measures of improvement. During 1885 the birth-rate and death-rate were respectively 32·8 and 14·6 per 1000. The highest death-rate—namely, 18·3 per 1000—prevailed in Hornchurch.

Whitechapel District.—Mr. Sloane commences his report by a kindly reference to the valuable labours of his predecessor, Mr. Liddle, who was a pioneer in public health work, and who was devoted to his duties almost up to the date of his death. On a population of 65,550 the death-rate for Whitechapel was 22·2 in 1885. It is shown, amongst other things, that the district has been favourably circumstanced as to small-pox, and it should be remembered that in Whitechapel vaccination has accounted for all but 1·6 per cent. of children born. The need for action under the Artisans and Labourers' Dwellings Acts for the Bell-lane district is prominently brought forward, and a hope is expressed that, though the matter has more than once been deferred, it will before long be dealt with.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5837 births and 2957 deaths were registered during the week ending June 5th. The annual death-rate in these towns, which had declined in the preceding ten weeks from 26·4 to 17·4, further fell last week to 17·0, and was lower than the rate recorded in any week since September last. During the first nine weeks of the current quarter the death-rate in these towns averaged 19·2 per 1000, and was 3·0 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 13·0 in Bristol and in Norwich, 13·4 in Hull, and 13·9 in Brighton. The rates in the other towns ranged upwards to 22·2 in Portsmouth, 23·3 in Cardiff, 23·8 in Bolton, and 31·9 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding eleven weeks from 430 to 278, were last week 279; they included 95 from measles, 74 from whooping-cough, 42 from diarrhœa, 29 from scarlet fever, 20 from diphtheria, 19 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Norwich, Derby, or Halifax; whereas they caused the highest death-rates in Bolton, Portsmouth, and Preston. The greatest mortality from measles occurred in Portsmouth, Blackburn, Bolton, and Preston; from whooping-cough in Cardiff and Portsmouth; and from scarlet fever in Salford. The 20 deaths from diphtheria in the twenty-eight towns included 13 in London, 3 in Portsmouth, and 2 in Manchester. Small-pox caused no death among the residents of London and its outer ring, or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 35 on each of the preceding two Saturdays, had declined to 25 at the end of last week; 4 new cases were admitted to these hospitals during the week, against 10 and 6 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding eleven weeks from 917 to 225, further fell last week to 179, and were 97 below the corrected average. The causes of 88, or 3·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Cardiff, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Halifax, Hull, Bristol, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had slowly declined in the preceding five weeks from 23·1, to 21·3 per 1000 further declined to 20·9 in the week ending June 5th; this rate, however, exceeded by 3·9 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 16·0 and 16·2 in Greenock and Aberdeen to 21·7 in Paisley and 25·2 in Glasgow. The 515 deaths in the eight towns showed a further decline of 11 from the numbers in recent weeks, and included 21 which were referred to whooping-cough, 19 to measles, 14 to diarrhœa, 6 to scarlet fever, 5 to "fever" (typhus, enteric, or simple), 3 to diphtheria, and not one to small-pox; in all, 68 deaths resulted from these principal zymotic diseases, against 44 and 60 in the preceding two weeks. These 68 deaths were equal to an annual rate of 2·8 per 1000, which exceeded the mean rate from the same diseases in the twenty-eight English towns by 1·2. The fatal cases of whooping-cough, which had been 11 and 17 in the preceding two weeks, further rose last week to 21, of which 16 occurred in Glasgow and 3 in Aberdeen. The 19 deaths from measles also showed an increase upon recent weekly numbers, and included 11 in Edinburgh, 5 in Leith, and 3 in Glasgow. No fewer than 119 deaths from measles have been recorded in Edinburgh since the middle of February. The 14 deaths attributed to diarrhœa in the eight towns last week, although showing an increase upon the numbers in recent weeks, were 2 below the number in the corresponding week of last year. All the 6 deaths from scarlet fever, and 2 of the 5 deaths referred to "fever," occurred in Glasgow; while 2 of the 3 deaths from diphtheria were returned in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 119 and 86 in the previous two weeks, rose again to 90 last week, but were 36 below the number in the corresponding week of last year. The causes of 84, or 16 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·7 and 26·0 per 1000 in the preceding two weeks, was 26·2 in the week ending June 5th. During the first nine weeks of the current quarter the death-rate in the city averaged 26·9 per 1000; the mean rate during the same period did not exceed 17·9 in London and 19·2 in Edinburgh. The 177 deaths in Dublin last week showed an increase of 1 upon the number in the previous week, and included 9 which were referred to the principal zymotic diseases, against 6 in each of the previous two weeks; 3 resulted from scarlet fever, 3 from whooping-cough, 2 from diarrhœa, 1 from "fever" (typhus, enteric, or simple), and not one either from small-pox, measles, or diphtheria. These 9 deaths were equal to an annual rate of 1·3 per 1000, the rates from the same diseases being 1·7 in London and 3·5 in Edinburgh. The 3 fatal cases of scarlet fever and of whooping-cough showed an increase upon recent weekly numbers, as did the 2 deaths from diarrhœa. Ten inquest cases and 3 deaths from violence were registered; and 59, or a third of the deaths, were recorded in public institutions. The deaths of infants showed a considerable decline, while those of elderly persons exceeded the numbers in recent weeks. The causes of 27, or 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY.—Staff Surgeon Fleetwood Buckle, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet; Fleet Surgeon Rinso Robert Siccama has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

The following appointments have been made: Fleet Surgeon Henry Hadlow, to Haulbowline Hospital; Staff Surgeon William E. Bennett, to the *Rupert;* and Mr. G. Newell to be Surgeon and Agent at Moville.

ROYAL NAVAL ARTILLERY VOLUNTEERS (Clyde Brigade).—Pierce Adolphus Simpson, M.A., M.D., and James Cowan Woodburn, M.D., to be Surgeons.

ARTILLERY VOLUNTEERS.—1st Inverness-shire: Hugh William Mann, Gent., M.D., to be Acting Surgeon.—1st Norfolk: Surgeon T. H. Moxon is granted the honorary rank of Surgeon-Major.—1st East Riding of Yorkshire: Edward Clarkson, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Hertfordshire: Surgeon D. B. Balding is granted the honorary rank of Surgeon-Major.—6th Lanarkshire: John Edmund Fairlie, Gent., to be Acting Surgeon.—2nd Perthshire (the Perthshire Highland): Wm. Gibb, Gent., to be Acting Surgeon.—2nd Volunteer Battalion, the Royal Warwickshire Regiment: Surgeon T. W. Thursfield is granted the honorary rank of Surgeon-Major.

THE VOLUNTEER MEDICAL STAFF CORPS.—London Companies: Eustace Augustus Burnside, Gent., to be Surgeon.

Correspondence.

"Audi alteram partem."

THE NEW SYDENHAM SOCIETY.

To the Editor of THE LANCET.

SIR,—I have been requested by the Council of the New Sydenham Society to seek your aid in bringing under the notice of those of your readers who are not its members a few facts as to our past history, present condition, and future prospects.

We are now in the middle of our twenty-eighth financial year (our financial year dating from January to December, subscriptions being due in advance, and our year of issue being from June to June). Our twenty-eighth year of issue of books begins this month, and the first volume of the year is in course of distribution to our members. It consists of a volume of short essays and papers, chiefly from German sources, on the "Relations of Micro-parasites to Disease," and it will be followed in the course of a month by the twelfth part of our "Lexicon of Medical Terms." We commence this year several new works, and the present is therefore an excellent opportunity for new members to join us. The hope of inducing a large number to do so is, let me say at once, my motive in asking insertion for this letter.

During our twenty-eight years of work we have enjoyed an income varying from £2000 to £3500, and have had a members' list which has averaged 3000. Of some of our more important works — such, for instance, as Trousseau's Clinical Medicine—we have been the means of sending abroad amongst the profession, in all parts of the world, not fewer than 4000 copies. The volume which is now going out counts as our 115th, which gives an average of considerably more than four volumes to each year. I must explain that in this calculation the parts of our Lexicon, and the fasciculi of our two Atlases, count as volumes. In each of the three years, 1880, 1881, and 1882, we issued six volumes; whilst on three occasions, one of which was last year, we have been obliged, by the state of our funds, to be content with only three. The two other years when this happened were 1863 and 1865. When I add that we have but seldom issued thin volumes, that we have been liberal in woodcuts and lithographs, and that we have had constantly in hand a very expensive Atlas (first of "Dermatology," and now of "General Pathology"), and more recently a yet more expensive "Lexicon of Medical Terms," I think I shall have justified the claim that we have achieved a very considerable amount of success. The maintenance of such a members' list through so long a series of years proves that our efforts to provide sound medical literature have been appreciated, and that in the main our publications have been approved.

Beginning with Dr. C. J. B. Williams, our first president, we have had in Sir Thomas Watson, Sir James Paget, Sir George Burrows, Mr. Cæsar Hawkins, Sir Prescott Hewett, Mr. Hilton, Dr. Peacock, Dr. Stokes, Sir W. Gull, Sir W. Bowman, and Sir Andrew Clark, a series of presidents who have all taken a vigorous interest in the Society's welfare. They have been constantly aided by members of the Council equally willing to devote time and labour to its interests. Of treasurers we have had but two. Up to the time of his death the duties of this post were discharged by the late Dr. Barlow: and for the last twenty years the Society has owed more than I can say to the alike able and indefatigable services of our present treasurer, Dr. Sedgwick Saunders. In its management, the Society has always aimed carefully at economy. Its expenses under the head of "Depôt," including agents' salary, distribution of books, and advertisements, have seldom been so much as a fifth part of the income, and often not a sixth. Our local secretaries have always given their valuable services gratuitously; and those services have, I know, often been very laborious.

I now come to the point to which I am especially desirous to ask general attention. It is this: that the Society is an organisation for the mutual advantage of its members; and that not only is its scope enlarged by increase of members, but that it gains directly in its capabilities of usefulness. With a small members' list, only a small number of books for the year can be issued; and with a larger one, that annual number is at once increased. It is, therefore, the direct interest of all members to endeavour to enlist others. When once the type for a book is set up, or the stone prepared for the plate, it costs very little to print off an extra thousand. If our members' list could be kept permanently at about four thousand, we could issue six volumes regularly every year with ease. I feel sure that this number might without difficulty be kept up if once its desirability were widely recognised. In the hope of offering attractions to those who have not joined us, permit me to enter into a little detail as to the works which we have now in preparation.

Our "Lexicon of Medical Terms," under the editorship of Mr. Power and Dr. Sedgwick, has now advanced fully half-way to completion, and its editors promise us to finish it in four years. I hesitate not to assert that, when finished, it will be, for completness and conciseness, without its equal in any language. The two large volumes to which it has already attained extend to the letter H, and constitute, even as they are, a most valuable addition to the practitioner's library. New subscribers will be allowed to procure these two volumes as the equivalents of two years' subscription.

Of our "Atlas of Pathology," a sixth fasciculus is now nearly ready, and, should our funds permit of it, others which are in preparation, will be regularly issued.

The "Atlas of Skin Disease" we regard as complete, and no more fasciculi of it will be brought out. It is out of print, and most of the stones have been destroyed.

The Council has come to the conclusion that, for the present at least, it will consider the issue of reprints of English authors concluded. It believes that the great activity of research which characterises the present day renders, as regards the larger number of its members, translations of recent publications more acceptable, and perhaps more useful, than reprints of the classics of the past. The same statement applies to collections of the scattered publications of recently deceased British writers. Our New Sydenham library, under these two classes, contains reprints from the works of Gooch, Bright, Addison, Latham, Smellie, Colles, Stokes, Graves, and Warburton Begbie. Although I believe that all of these were well worthy the Society's adoption, and were very acceptable when issued, yet I also quite think that the Council has acted wisely in deciding to devote all available funds in future to translations of recent books, and to the completion of our "Pathological Atlas" and "Medical Lexicon."

In reference to the observation sometimes made that it is better to read foreign works in their original tongue, I may ask attention to the fact that some of the Society's books are by no means mere translations. The volume of Billroth's "Clinical Surgery," prepared for us under the editorship of Mr. Clinton Dent, comprises the cream of many separate books and reports, not very easy of access. It would be a boon to the German profession if, in its present form, our book were translated back into that language. The same remark applies to Dr. Vivian Poore's single-volume edition of the very able, but very diffuse, publications of the late Dr. Duchenne of Boulogne. Every member of our Society possesses a far better compendium of Duchenne's works than any which the author's fellow-countrymen can possibly procure in their own tongue. A volume of the same class is in preparation, to comprise the most valuable parts of Alfred Fournier's works, and the work on Micro-parasites, just edited for us by Mr. Watson Cheyne, may claim something of the same character. Our two volumes of German "Clinical Lectures" were also carefully selected, and gave to our readers the best of the voluminous series which appeared in the original.

Of the works on which translators for the Society are now actually engaged, I may mention the following:—Hirsch's "Manual of Geographical Pathology" (Dr. Creighton); a third volume will conclude this work. Cohnheim's "General Pathology" (Dr. McKee). Spiegelman's "Midwifery" (Dr. Hurry), undertaken on the strong recommendation of Dr. Matthews Duncan, Dr. Barnes, Dr. Herman, and others. This work is a large and freely illustrated manual of the subject, which has attained great popularity abroad. Dr. Barlow has in hand for us the original essays of Dr. Raynaud on the disease which is likely in the future to bear his name, and Dr. Fancourt Barnes has translated Neugebauer's monographs. Another volume of Charcot's "Clinical Lectures" (not as yet quite complete in the original) has been adopted, as have also the works of Flugge on Micro-parasites, Litzmann on Contracted Pelvis, and Band's two short monographs on special subjects in connexion with pregnancy and labour. A third volume of German "Clinical

Digitized by Google

Lectures" is contemplated, and many other works have only been put aside by the Council because it cannot see its way to the probability of being able to afford to issue them within a reasonable period. There is no lack of works in foreign languages, the reproduction of which in English would be a direct and great boon to professional knowledge amongst ourselves. No machinery can possibly be devised better fitted for the production of such works than a mutual translation company, such as is our Society. The works which we publish cost our members certainly less than half of what they would do if purchased through the trade. The recent remarkable cheapening of medical works has, I have no doubt, to some extent conflicted with our interests. It is, however, a fact on which we congratulate ourselves, partly because we believe that what we have done has had a share in bringing about the reformation, and in part because it helps to attain the end which the Society seeks. When, however, medical publishers have done the utmost that enterprise can attempt, we still feel that there will be abundant room for our Society's special function. In that belief, on behalf of the Council, I now appeal to the English-speaking profession all over the world to come forward and recruit our ranks. We have no formalities of election, and all who send their names and subscriptions are enrolled at once. Those who may possibly feel, respecting some of our works, that they do not personally wish to possess them, may yet have the satisfaction of knowing that they are helping the success of a Society which has in the past done much honest work in the cause of medicine, and which trusts to be enabled in the future to do much more.

I am, Sir, yours truly,

JONATHAN HUTCHINSON,
Hon. Secretary, New Sydenham Society.

Cavendish-square, W., June, 1886.

LEICESTER AND ITS IMMUNITY FROM SMALL-POX.

To the Editor of THE LANCET.

SIR,—Your Special Commissioner has visited Leicester and discovered that the immunity we have enjoyed from outbreaks of small-pox is due to our "sanitary and disinfecting appliances," *plus* vaccination and revaccination of medical officer of health, hospital nurses, inspectors, &c. His statements in regard to the extent of the revaccination are somewhat exaggerated, but that is of little consequence; what I do complain of, however, is that your Commissioner should assume that the plan adopted by us as a sanitary authority has anything whatever to do with opposition to vaccination, or has any reference to the opinion of the people for or against that article of the medical faith. If vaccination were unknown our "sanitary and disinfecting appliances" would be necessary: if vaccination and revaccination were universal our methods would still be invaluable. Your Special Commissioner says, speaking of the vaccination of officials, "Without this protection of vaccination the perfect sanitary arrangements of Leicester would break down in a month"; and he adds, "If her sanitary authorities really believe in their sanitary and disinfecting appliances *per se*, let them put our statements to the test; let them remove the *cordon* of protected persons about the cases, and their boasted arrangements will prove a delusion." I am at a loss to understand why such a proposition should be put before us. I explicitly stated to your Commissioner that the sanitary authorities here did not pursue their methods of treating small-pox cases, when they arose, with any idea of setting up a theory as against vaccination. The sanitary authority is not connected with the anti-vaccination movement, and it has nothing to do with enforcing the law of vaccination—that duty being cast upon boards of guardians. If we discontinued our "sanitary and disinfecting appliances" I have no doubt we should soon have the terrible scourge so often promised us by medical men—but we do not intend to discontinue them; and as to the "*cordon* of protected persons," that is a matter for the officer of health, with whom we do not wish to interfere.

This conclusion, however, is apparent to all who study the subject: in Leicester, with vaccination largely neglected, small-pox does not spread; in many other towns where vaccination is religiously observed the epidemics of small-pox are constantly recurring. Surely it is this fact which should attract the attention of the profession, for if they agree with us, as they now say, that sanitation *plus* vaccination and revaccination is *the* cure and remedy for small-pox, how it is they cannot point us to towns where they have had equal immunity with Leicester from the dread scourge?

Would it not have been wiser if your Special Commissioner had impressed upon other authorities the desirability of adopting the sanitary arrangements carried out here, which he admits are "perfect," instead of bringing a railing accusation against us, and submitting to us an extraordinary proposal as to withdrawing the *cordon* of protected persons from the infected cases, as though we set up our sanitary appliances to prove the worthlessness of vaccination? I venture to submit that the sanitary authorities in this town have adopted a plan of dealing with this horrible disease, when it is imported into our midst, which deserves the highest commendation; and personally I feel that we are under the deepest obligation to the late medical officer of health, Dr. Johnston, by whom the method was first introduced. A great amount of human suffering, misery, and pecuniary loss, and in all probability many deaths, have been prevented by the course we have pursued; and I see no reason why these blessed results should not follow the carrying out of the same methods in other towns.

I am, Sir, yours truly,

THOS. WINDLEY,
June 7th, 1886. Chairman, Sanitary Committee, Leicester.

*** We are glad that the chairman of the Sanitary Committee has so little to find fault with in our Commissioner's demonstration that Leicester is protected from small-pox by vaccination and revaccination. It is also satisfactory to find that the sanitary authorities have evidently no intention of trying the experiment of perfect sanitary arrangements *minus* vaccination. No sanitary arrangements will save those exposed to small-pox from taking it, though such arrangements ought to be enforced in all towns. Our Special Commissioner cannot admit any exaggeration in his statement of the extent of revaccination of exposed persons. He has rather to confess to a great under-statement which we may now supplement—though it is part of what should not be told in Gath—that the chairman of the Sanitary Committee himself is *revaccinated!*—ED. L.

BURIAL REFORM.

To the Editor of THE LANCET.

SIR,—Referring to your annotation in last week's LANCET, it appears to me that the reforms needed now in our present burial system have been narrowed to within a very small compass, and comprise simply (*a*) the construction of the coffin, (*b*) the mode of conveying it to the grave, and (*c*) the formation of the grave itself. Having within the last seventeen years witnessed the removal of five burial-grounds, and the exhumation of hundreds of bodies therefrom, as well as of others for medico-legal purposes, I am perfectly satisfied that if burial is to continue as the more general method of disposal of the dead, it must be in accordance with the "earth-to-earth" system so ably advocated by Mr. Seymour Haden. Admitting, which I freely do, all the advantages of cremation, I see many objections to and difficulties in the way of its general adoption. Hence it appears to me wiser that we should concentrate all our efforts in improving the present mode of burial.

In three cases of poisoning by arsenic, in which the deceased were just above the level of paupers, and had been buried in common graves, the coffins, all of pine deal, were intact after ten months, fifteen months, and even three and a quarter years' burial. I have seen, in a damp soil, coffin boards preserved after thirty or forty years' burial. On the other hand, in a dry, suitable soil, I have seen everything absorbed into the earth except the skeleton, coffin plate, and the handles. Even the skeleton will, I believe, in time disappear and mingle with the earth. These facts of the past ought to guide us in our regulations for the future. The leaden coffins, with vault or bricked grave burials, are slowly becoming things of the past. But the wooden coffins still used are too massive and heavy, as well as much too imperishable. It is evident that even pine deal, which is said to be the most perishable of all woods, is not perishable enough

Digitized by Google

It is therefore unsuitable, and some other material is desirable. The "earth-to-earth" coffins appear to supply what is required, being constructed of material sufficiently strong to convey the body to the grave, but not to retard the resolution of the body to the earth; on the contrary, they are said to facilitate disintegration and absorption. Their use, therefore, ought to be promoted in every way.

It is greatly to be regretted that undertaking monopoly should have been successful in retarding the use of the "hand bier," or bier on wheels. Their superiority to the practice of carrying the body on the shoulders of bearers is obvious, and requires no arguments in their favour, being more economical, safer, and more wholesome.

The arguments in favour of burial in the earth, pure and simple, are overwhelming. They have the sanction of religion, of law, and of sanitation. It is with the latter aspect that we have to deal. In advocating cremation, Sir Spencer Wells wrote just twelve months ago a letter, of which the following is an extract.

"In this metropolitan district, in the twenty-five years 1859 to 1883, the deaths registered number 1,896,314. Of course the dead have been buried, and, with scarcely an exception, in and around London. Grant that in ten years a body may become harmless—although I do not at all believe that it does so within twenty years in our soil and climate,—can any imagination conceive the enormous mass of decaying animal matter by which we are surrounded? Could anyone be surprised at the outbreak of some devastating pestilence a hundredfold more destructive than the plague or black death of the middle ages?"

These remarks apply rather to the manner than the number of burials. Were all these bodies buried in suitable coffins, and in a sufficiency of dry soil, no harm could possibly result to the living. With proper burial our cemeteries might be made to serve not only the present but future generations. In all that relates to the actual burial of the body, medical practitioners are strictly within their province in advising such mode of burial of the dead as is least hurtful to the living, as well as most effective of its purpose; and the work of the Church of England Funeral and Mourning Reform Association deserves in these matters the hearty support of all members of the profession.

I am, Sir, yours faithfully,

Liverpool, May 31st, 1886. FRED. W. LOWNDES.

DEGREES FOR LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—In the discussion on the subject of degrees in medicine, nothing has been said about the important fact that without a degree a man cannot obtain the post of physician to any good hospital. It is no wonder that the public attaches so much value to the title of M.D. when the profession itself has always thus made such a point of doing so. How, then, can we expect a young colonist and others to forego the acquisition of a Scotch M.D. after he has been shown that a medical degree is the passport to the post of physician at a hospital in this or in his own country. The degree, therefore, which is to be given in London must not rank in a title only, but it must confer privileges similar to those implied by the possession of a University degree.

I am, Sir, yours truly,

June, 1886. Z.

EDINBURGH.

(*From our own Correspondent.*)

EDINBURGH UNIVERSITY.

IT has been decided to institute a new degree in connexion with the University Faculty of Science, as a goal attainable by students of agriculture who have till now received no university recognition at the end of their studies. The course of study will extend over three years, commencing from the completion by candidates of the usual preliminary examination in general knowledge. There is to be an intermediate examination upon the general applications of the various sciences to that of agriculture, after passing which the student may proceed to the final examination when he has completed an additional session, the final examination dealing chiefly with more purely technical matters. The practical departments in connexion with this new curriculum have been thoroughly elaborated, the surrounding districts of the Lothians having been put under requisition to supply the necessary opportunities of personal training in various practical details. Candidates who successfully pass the final examination will receive the degree of B.Sc. in Agriculture, and will bear with it a recognition as thoroughly trained agricultural scientists.

POST-GRADUATE HOLIDAY COURSES.

An attempt is at present being made in Edinburgh to arrange for a series of clinical demonstrations, to be held during October, for the sake of medical graduates of this school who might find it convenient to revisit Edinburgh for a short time at that season, and by means of which they might have personal opportunities of observing the most recent advances made in the school in the methods of treating various diseases. It is not proposed, in the meantime at least, to set on foot distinct courses for medical men upon the various branches of clinical work; but it is hoped that an arrangement may be made by which facilities for clinical instruction under our ablest teachers may be afforded to all such as may attend. A meeting of all the clinical teachers in the school has been summoned to meet in the board-room of the Royal Infirmary, under the presidency of Sir Douglas Maclagan, to discuss the subject. Should their deliberations prove satisfactory, it may be confidently hoped that a most important branch in the work of this school as a teaching centre will have been established. Experience elsewhere has shown that such arrangements afford a golden opportunity to the practitioner of which he is not slow to avail himself; and there can be little doubt that, if the preliminary difficulties in the way of concerting arrangements and concentrating the whole force of the teaching fraternity can be surmounted, the proposal will lead to a most successful result.

MEDICO-CHIRURGICAL SOCIETY.

At the last meeting of this Society an interesting case of atrophy of the whole upper extremity following diffuse cellulitis was exhibited by Mr. A. G. Miller. The atrophic process was not confined to the soft parts, but involved also the bones. Ankylosis had taken place at all the joints. Dr. Jamieson communicated some interesting results of new methods of treatment in diseases of the skin; he demonstrated the methods of application of several remedial agents introduced by Dr. Unna of Hamburg, and showed the results of treatment in the case of several patients. Perhaps the most important of these remedies is that employed as a varnish in intractable eczema in the moist stage—a glycerin-jelly, containing as its most active ingredient the sulphoichthyolate of soda, combined with extract of cannabis indica, to allay the irritation. This rapidly accelerates the progress of the condition from its moist to its dry retrogressive stage. Dr. J. S. McLaren read an interesting communication upon the effects of the inhalation of flame. The paper was illustrated with specimens and drawings, which demonstrated very clearly the lesions produced. A point of considerable interest was that in the case upon which the communication was based, marked duodenal lesions were found after death, which occurred in less than nine hours from the time of the accident.

THE MELBOURNE CHAIR OF CHEMISTRY.

The Chair of Chemistry in the University of Melbourne has been filled by the appointment of Dr. Orme Masson, a graduate of, and Research Fellow in, the University of Edinburgh. Dr. Masson is a son of Professor Masson, of the Chair of English Literature and Rhetoric in the University. He is a Doctor in Science of this University, and a Fellow of the Royal Society of Edinburgh and of other learned societies. In chemistry, to which he has devoted his undivided energies, he has had a career marked by success, both in his original investigations and in recent contributions to the literature of the subject in certain branches. His appointment will be a great gain to the University of Melbourne, for he has shown himself no less successful as an organiser and administrator than as a specialist in his own department of science.

Edinburgh, June 8th.

AT a meeting of Volunteer officers, held on the 8th inst. at the Bristol Medical School, it was resolved to establish a branch of the Volunteer Medical Association for the City, and to call a public meeting in reference to the formation of a medical staff corps.

GLASGOW.

(From our own Correspondent.)

THE FACULTY'S REPRESENTATIVE AT THE GENERAL MEDICAL COUNCIL.

THE vacancy in the General Medical Council, caused by the lamented death of Dr. Scott Orr, has been filled up by the appointment of Dr. D. C. M'Vail as the representative of the Faculty of Physicians and Surgeons. Dr. M'Vail was largely supported by those who look for some result from the infusion of new blood (and younger blood into the Council. He will be the youngest member of that body; and if he manifests the same energy and exercises the influence at its meetings that he does at meetings of the Faculty, the venerable brethren of the Council may look out for stirring times.

ROYAL INFIRMARY MEDICAL SCHOOL AND THE UNIVERSITY.

A few weks ago reference was made in THE LANCET to the movement for the erection of the above-named school into a College of the University. Since then the directors of the infirmary have not been idle. They have had a deputation in London interviewing the Lord Advocate, the Scotch Secretary, and other influential persons, for the purpose of furthering their object. This deputation has returned highly pleased with the favourable impression they have made. They profess to have secured promises of support from many parliamentary men, and to have so advanced their cause as to render ultimate success pretty well assured. So far the University side of the question has not been heard. The projected change is one which profoundly affects the future position of our universities, and of the extra-mural schools, not only in Glasgow, but elsewhere. The public press, moreover, has taken the question up, urging strongly the adoption of the changes proposed. The University, therefore, if it wishes to influence public opinion on the subject, should lose no time in making some statement of the case from its own point of view.

GLASGOW PHILOSOPHICAL SOCIETY AND M. CHEVREUL.

This Society has done honour to M. Chevreul (and to itself) in preparing and forwarding to that distinguished scientist a neat little address, congratulating him on the near approach of his hundredth birthday. M. Chevreul has been an honorary member of the Society since 1860.

HIGH DEATH-RATE AT IRVINE.

During the month of May the death-rate for the whole of Irvine was 34·78, but in one district, the Half-way district, with a population of over 4000, it reached the alarming average of 50·85 per 1000; this high mortality being due to an epidemic of scarlet fever. In what is called the "old burgh" the rate was 20·58.

Glasgow, June 8th.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

A MEETING of the Fellows was held on Saturday, the 5th inst., to receive the Annual Report of the Council, and discuss any matters affecting the interests of the College which might be brought under their notice. The following notice of motion by Mr. J. Kellock Barton was, in his absence, proposed by Mr. Edward Hamilton:—"That the incoming Council be recommended to do their utmost to obtain such satisfactory union between the existing corporations as will result in the formation of one examining body qualifying in medicine, surgery, and midwifery; and further that the Council be specially recommended to prevent by every means in their power legislation which would result in any of the existing corporations being entitled to issue a complete and registrable title to practise." Mr. Hamilton urged that if a conjoint scheme should be adopted, the Apothecaries' Hall should not be excluded from the arrangement. Mr. Whistler seconded the resolution. Dr. Kidd believed that the Bill now before Parliament was a good one, although it had a weak point, but it would settle the agitation about medical reform. He thought the recommendation to the Council unwise, it should be left an open matter, as they were perfectly aware of the importance of the subject, and they should use their own discretion. They should be very careful not to jeopardise the Bill. Mr. Jacob supported the resolution, and pointed out that if the College of Physicians objected to the Apothecaries' Hall joining in the proposed scheme, the latter body could claim the right of obtaining coadjutor examiners from the Medical Council, and could issue licences in medicine, surgery, and midwifery, in accordance with the clause adopted by Sir Lyon Playfair. Should this arise, their licence would be issued for a nominal sum. The resolution was adopted. On last Monday, the 7th inst., the annual election of office-bearers for the ensuing year took place. Mr. Stokes was returned unopposed as President, and in the contest for the vice-presidency between Mr. Corley and Mr. Fraser, the former was successful, having obtained a majority of votes. Mr. William Colles was also elected secretary without opposition. No change took place in the election for Council, except that Mr. H. Gray Croly succeeded to the vacancy due to the resignation of Mr. Wharton. One hundred and ninety-eight Fellows voted, an unusually large number. The President having left the chair, Dr. Kidd, the senior member of Council present, moved a vote of thanks to Sir Charles Cameron for the dignity with which he had occupied the chair and the efficient manner in which he attended to the duties of his office while acting as president. This was seconded by Mr. W. A. Elliott, and passed with acclamation. During the unavoidable absence of the new President (Mr. William Stokes) Sir C. Cameron will perform the necessary duties appertaining to the office. I shall probably refer next week to the annual report of the Council for the past year.

BELFAST HOSPITAL SATURDAY.

On Saturday week street collections were made in aid of the funds of the Belfast Royal Hospital, and a sum of £320 obtained. This is the third year these collections have been organised, and each year shows a considerable falling off in the amount received. The organisation for collecting subscriptions from the charitable public was complete, and the various ladies and gentlemen worked with all possible zeal and energy, but the result must be regarded as discouraging.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The forty-fourth annual meeting was held last Monday, and from the report adopted by the meeting it appears that a sum of £1203 has been awarded, of which £157 had already been distributed in anticipation of the general meeting. Of the amount distributed during the year, £185 was to medical men, £932 to widows, and £86 to orphans. In accordance with an order of the Master of the Rolls for a readministration of the will of the late Mr. Carmichael, a sum of nearly £100 will shortly be handed to the Society by the Council of the Royal College of Surgeons. The contributions from India for the past year were much below the average.

Dr. Murphy, late assistant-physician to the Mater Misericordiæ Hospital, has been appointed physician to that institution; and Mr. C. B. Gaffney has been elected assistant-surgeon to Vincent's Hospital, in the vacancy caused by the promotion of Mr. Tobin.

Steevens's Hospital will receive a legacy of £2000 under the will of the late Mr. R. N. Moore, of Southern New Mexico.

Dublin, June 8th.

PARIS.

(From our own Correspondent.)

A CASE OF HEREDITARY INSANITY.

ABOUT the middle of last year three Frenchwomen, sisters, and spinsters, were implicated in the murder of an old lady, who was also a spinster, and in whose service one of the former was employed as housekeeper. The murder had been committed some time previously by poisoning, the body cut to pieces, which were steeped in lime and buried in the garden of the old lady at Villemomble, a small suburban town near Paris. They were tried for the crime, one as the murderess, and the other two as accomplices, but judgment was suspended on the recommendation of the late Dr. Legrand du Saulle, medical expert to the judicial courts of Paris, on the grounds of irresponsibility, as they were of

Digitized by Google

unsound mind. This shrewd observer's diagnosis has been confirmed by Professor Ball, the eminent alienist and physician to the Sainte-Anne Asylum, where the three accused women were kept under observation. About a week ago Professor Ball delivered a very interesting clinical lecture at the asylum, to prove the irresponsibility of these women with regard to the crime with which they are accused. He also presented them to the audience one after another, and pronounced them to be hereditarily insane. They are all three the subjects of mystic insanity ("folie mystique"), which, the lecturer observed, differed physiologically from persecution mania ("délire des persécutions") in the sense that in the first case it is the sight which perceives, whereas in the second it is principally the hearing. The first that was introduced was Honorine Mercier, aged fifty-five. The Professor then asked her to give an account of one of her visions, which she did without any hesitation; it was as follows:—"I had the first vision at the age of eleven years. It was the night of my first communion. On awaking, I saw, to my great astonishment, that the candle was lighted. Whilst looking at it, I felt myself all at once lifted up in the air. I arrived in the midst of a delicious atmosphere, very respirable and altogether perfumed. I was in heaven. I felt nothing in me of matter, and yet there flowed in my veins something like the waters of felicity. Then followed the most exquisite music. It was the angels who were singing to God. This lasted four hours, after which I found myself in my bed." While citing the above, her features, which were very mobile, appeared to reflect each of the ecstatic sensations which her dream might have caused. During her recital she mixed up with her phrases extracts from sermons, biblical citations, sometimes pleasantry of rather doubtful propriety. After this, Honorine related how, in one of these visions, she believed herself to be the victim of an *enlèvement*, or being carried off forcibly. Sidonie Mercier is less disposed to speak than Honorine; she is of a passive nature, and one has to draw words from her. As for Euphrasie, the convicted, she has all the mysticism of her sister Honorine. Like her, she has visions, she hears voices, she obeys the orders given by God, &c. Professor Ball affirms that Euphrasie is a lunatic. The object of the murder was to appropriate to herself the property of her mistress, consisting of the house they lived in, and a large sum of money in banknotes, coupons, railway shares, &c., the changing of which excited suspicion and the ultimate discovery of the crime.

THE SCHOOL OF PHARMACY.

The reopening of the School of Pharmacy took place yesterday, and nothing unusual occurred, as, at Professor Chatin's request, M. Gérard, his botanical assistant, has been appointed *pro tem.* He is very popular with the pupils. Professor Chatin adopted this step to prevent a renewal of the scandal which took place at the opening of the Botanical Lectures, which has been reported in THE LANCET. Meanwhile, an inquiry is being held, as the students, in a letter to the Minister of Public Instruction, have formulated certain charges against Professor Chatin, the result of which has not as yet been made known.

M. PASTEUR.

M. Pasteur is winning more laurels. He and M. de Lesseps, who has also distinguished himself, have been awarded medals by the French Humane Society, in recognition of the services rendered by them to humanity, though in different ways. M. Pasteur has just presided over a new branch of the Philanthropical Society of Paris, which is intended for the reception and care of women and their infants leaving the Lying-in Hospital, which they are obliged to do on the ninth day after confinement, unless the mother is too ill to be removed. The subscriptions to the Pasteur Institute, according to the last report, just published in the Official Journal, amount to 1,194,182 fr., which sum includes 300,000 fr. lately voted by the Senate, and as much by the Chamber of Deputies.

Paris, June 8th.

YELLOW FEVER AT CARACAS.—The following communication has been issued from the Foreign Office:—"Her Majesty's Minister at Caracas reports great mortality among British subjects resident there, and states that many English mechanics are induced to emigrate to Venezuela under false impressions as to the climate, a better knowledge of which would enable those who thus risk their lives to obtain better terms."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the College, held on Thursday last, the following Examiners were appointed:—Medicine: Dr. Moxon and Dr. Payne; Dr. Gee and Dr. F. T. Roberts were re-elected. Midwifery: Dr. Williams and Dr. Herman were re-elected. Dental Surgery: Mr. J. S. Turner (in the place of Mr. Moon, resigned); Mr. C. Tomes was re-elected.

The following report from the committee on the question of the conferring of degrees in Medicine and Surgery by the two Colleges in combination was approved, adopted, and entered in the minutes:—

"The Committee have further considered the question referred to them by the Council, together with the communication, dated February, 1886, from the Executive Committee of the Association for promoting a Teaching University in London, and the letter of the 27th ult. from Sir Henry Pitman, M.D, and accompanying Report from the Council of the Royal College of Physicians relating to the subject, also referred to the Committee by the Council on the 11th of March last and 13th ult. respectively, and submit for the approval of the Council the following recommendations—viz.: 1. That it is desirable that degrees in Medicine be conferred on candidates who have passed the examinations of the Examining Board in England by the Royal Colleges of Physicians and Surgeons. 2. That the terms upon which titles shall be conferred be referred to the Committee of Delegates of the two Colleges to consider the same and report thereon."

It was agreed that three additional delegates be appointed, provided a similar number be appointed by the Royal College of Physicians.

Sixteen delegates were selected to confer with a similar number already appointed by the Royal College of Physicians, as to the disposal of the portion of the site not occupied by the Examination Hall.

There will be an extraordinary meeting of the Council on the 24th inst., for special business.

Obituary.

FRANCIS MASON, F.R.C.S. ENG.

IT is with deep regret that we have to announce the great loss sustained by the profession through the death of Mr. Francis Mason, of 5, Brook-street, Grosvenor-square, in his forty-ninth year. The deceased was the youngest son of the late Mr. Nicholas Mason, of Wood-street, Cheapside. His early education was conducted at the Islington Proprietary School, the late Bishop Jackson being then head master, and at the King's School, Canterbury. He matriculated at the London University, and afterwards received his professional education at King's College, London, of which he was an Honorary Fellow. In the progress of his studies it was early observed that his aim was particularly directed towards cultivating the art and practice of surgery, and there are many who may remember his marked zeal and interest when performing the duties of dresser in the surgical wards of his hospital. He was prizeman in Surgery of his year, and at that time was present at many of the private operations of the late Sir William Fergusson, by whom he was highly esteemed, and whose intimacy and friendship he retained till the time of Sir William's death in 1877. He became Fellow of the Royal College of Surgeons in 1862, and at the date of examination he was the youngest on the roll of Fellows. His first public hospital appointment was that of surgeon to the St. Pancras and Northern Dispensary. He then became consecutively assistant-surgeon to King's College Hospital and surgeon and lecturer on anatomy at the Westminster Hospital. When the new St. Thomas's Hospital was opened in 1871, Mr. Mason was among the distinguished men, hitherto connected with other hospitals, who were invited by the governors to join the medical staff. He was appointed assistant-surgeon, and also joint-lecturer on anatomy. In both departments he won general regard and esteem by the thoroughness of his work. In 1876, on the retirement of Mr. John Simon, he became

Digitized by Google

surgeon to the hospital, and when he resigned the lectureship in anatomy, he was made lecturer on practical surgery. This chair was eminently suited to the display of his remarkable technical skill and ingennity. His teaching was most attractive, and his classes were much valued and abundantly attended. In his teaching in the wards, Mr. Mason was careful to train his class in the details of minor, as well as put before them the principles and practice of major, surgery. He thus gave them just the kind of training which would be useful in ordinary practice. Many a man now in practice remembers gratefully the excellent instruction which he received from him.

He was a fellow and member of several of the learned Medical and Surgical Societies in London, and was honorary member of the South Hants Medical Society. He delivered the oration at the Medical Society of London in 1870, and was president in 1882, during which year of office he exhibited great interest in the work and success of the Society, which efforts were rewarded by a largely increased number of members. He was Lettsomian Lecturer in 1878, the subject of the lecture being "The Surgery of the Face," and he was the author of a work entitled "Hare-lip and Cleft Palate," in which operations he acquired a large reputation both at home and abroad. He was also the author of several other papers and cases of surgical interest, which have been published.

The subject of this memoir was a thorough gentleman, with refined tastes, and possessed a large connexion and circle of friends. He was, through the kindliness of his disposition, delicacy of his feelings, and uprightness of conduct, endeared to all who knew him. It was always in accordance with his inclination, both in the practice of his profession and in private life, to be painstaking, chivalric, accurate, systematic, and genial to a remarkable degree. His generosity of disposition and hospitality are well known, and these, combined with his great social powers, musical attainments, and bright humour, rendered him distinguished in society.

The suddenness of his decease has caused to the profession and his friends feelings of the greatest pain and consternation. His illness was erysipelas of the upper larynx, with diffuse inflammation of the tissues of the neck. Swelling was observed on the right side of the neck at the level of the thyroid cartilage, and at the same time there were swelling and redness in the fauces just below the right tonsil. In a few hours the whole of the upper larynx was swollen, with an intensely congested œdema, while the neck had become deeply infiltrated on both sides. Inhalations gave little relief, and at 7.30 P.M. on Thursday (the illness having commenced only in the morning of that day) Dr. Semon scarified the swollen epiglottis. For some hours after this the patient was easier, but about 2.30 A.M. on Friday he suddenly ceased to breathe. Mr. Pitts, who was watching him, at once performed tracheotomy, under circumstances of great difficulty, only Mr. Mason's wife at the time being present. After the tube had been inserted, there followed an attack of epileptiform convulsions. These presently passed off, and the patient, recovering his consciousness, was evidently greatly relieved; but it was apparent, even then, that the constitutional aspect of the illness was as serious as the local condition: the pulse was very quick, ranging above 160, and the respiration was irregular and, so to speak, ataxic. It was one of the forms of the so-called Cheyne-Stokes' respiration. The pulse fell in quickness and rose in strength during the morning of Friday, but the breathing never became quite natural in rhythm. The improvement ceased on Friday evening, when delirium set in. Early on Saturday morning Mr. Mason appeared again to revive, having been able to take liquid food and stimulants; but the revival was transient; his strength gradually failed, and he died at the moment when his medical attendants had met for consultation. The nature of the illness was to all appearance septic. The urine examined in the night of Thursday was loaded with albumen, and also contained much sugar; chlorides were suppressed. Under the microscope there were seen granular and hyaline casts, and later on some blood-corpuscles. It is possible that there may have been some antecedent interstitial change in the kidney, but probably the greater part of the albumen and all the sugar were present only as the result of the intensely acute attack. On Saturday morning the albumen had diminished very greatly, and the sugar reaction could hardly be obtained.

Dr. Ord (from whom, and by Dr. Buzzard, the above medical details have been obtained) had entire charge of the case from the commencement of the illness. Dr. Ord was quickly joined in his attendance by Dr. Semon, Mr. McKellar, Mr. Pitts, Mr. Clutton, and by Dr. Buzzard, who were unremitting in their attention, but, notwithstanding their combined efforts and skill, could not combat the disease, and the patient succumbed at 1.50 on Saturday afternoon. It is remarkable that Mr. Mason at the onset of his illness ordered his tracheotomy instruments to be placed in his bedroom in readiness. He leaves a widow, daughter of the late Benjamin Stephenson, Esq., of 25, Tavistock-square, to lament her loss. The funeral, which was attended by nearly the whole of the medical staff of St. Thomas's, as well as a large company of the private friends of the deceased surgeon, took place at Highgate Cemetery on Wednesay last.

JAMES APJOHN, M.D., F.R.S.

THIS well-known gentleman died last week at his residence, South Hill, Blackrock, at the advanced age of ninety-one years. Dr. Apjohn was born in 1794 in the county Limerick, and was educated at the Diocesan School, Tipperary, and afterwards entered Trinity College, Dublin, where he obtained, among other honours, a scholarship in 1816. In 1821 he obtained the degree of Bachelor in Medicine, and four years afterwards was connected as lecturer in Chemistry—a subject to which he early devoted his attention—to the Park-street School of Medicine. His fame as a chemist soon spread, and in 1828 he was elected Professor of Chemistry in the Royal College of Surgeons, Ireland, and in 1850 to the chair of Chemistry in the University of Dublin. In 1853 he was elected a Fellow of the Royal Society. He was the author of various papers on subjects connected with chemistry, and in 1837 was the recipient of the Cunningham Gold Medal of the Royal Irish Academy for his treatise on a "New Method of Investigating the Gaseous Bodies." About twelve years since he resigned his chair in Trinity College, and subsequently the post of representative of the University on the General Medical Council. He enjoyed extremely good health until a short time before his decease.

JOHN GAVARON TREACHER, M.R.C.S., L.S.A.

BY the death of John Gavaron Treacher on May 14th, at his residence at Kew, an interesting link with the past has been severed. He was born in 1814, and entered at St. Bartholomew's Hospital in 1833, a contemporary of Paget and Burrows. He passed his M.R.C.S. examination in 1836, and his diploma bears the names of Astley Cooper and Brodie. His life for the next few years was full of singular adventure. Having relinquished an assistancy in Bloomsbury, he embarked in 1838 as surgeon on board Sir James Brooke's man-of-war on the expedition to Sarawak. Subsequently he accompanied the Rajah, with whom he formed an intimate and abiding friendship, in many of his perilous encounters with the pirates of the Eastern Archipelago, on one occasion suffering shipwreck and losing everything. Mr. Treacher was subsequently appointed colonial surgeon and member of the Legislature of the island of Labuan; here he suffered severely from an attack of the so-called Labuan fever, to which he attributed much of his later ailments. He returned to England, and received a warm welcome from his friends at home; but his roving nature would not allow him to remain long in England, and he returned to the East, where he acquired an island named Pulo Dea, and there occupied his leisure with cocoa-nut plantations. Failing health caused him to settle down in England, but he paid several visits to his old haunts, and even talked of starting again. Mr. Treacher suffered latterly from painful attacks of asthma and angina pectoris, and shortly after one of these he rather suddenly passed away; he had been successfully operated on for cataract in both eyes some years before his death. Mr. Treacher did not practise after his return to this country, having become independent of his profession. His genial, kind, and courageous spirit endeared him to his many relatives and friends. He was never married, but was nursed with devotion during his last illness by his two sisters. His cousin, the Hon. W. H. Treacher, is now Governor of British North Borneo.

MEDICAL NOTES IN PARLIAMENT.

Purification of the Lea.

IN the House of Lords, on the 8th inst., the River Lea Purification Bill was read a second time.

The Science and Art Department and Medical Schools.

In the House of Commons, on the 7th inst., in reply to Mr. Cozens-Hardy and Dr. Farquharson, Sir Lyon Playfair stated that, acceding to a request made and initated by a joint-committee of the four unendowed hospitals—viz., Charing-cross, Middlesex, St. George's, and Westminster—an arrangement has been made by the secretary of the Science and Art Department for the admission of certain students from their medical schools to that part of the courses which is limited to elementary instruction in biology, physics, and chemistry at the Normal School of Science at South Kensington. The only thing special in regard to the fees was that they were slightly raised; for whereas for the elementary instruction in those sciences the annual fee is £50, the medical students will have to pay not £33, but £35, with about £3 in addition for apparatus. Medical students have attended science classes in the Government school for the last twenty years, and care has always been taken that the fees charged should not be so low as to compete with private schools.

The Insanitary State of the House.

In reply to Mr. Isaacs, Mr. Leveson-Gower stated that orders were given last week for carrying out the works proposed by the committee for the improvement of the ventilation of the kitchen. It will be impossible to complete them during the period of an ordinary recess, but they will be so completed in a short time after the House reassembles.

Medical News.

ROYAL UNIVERSITY OF IRELAND. — The following Honours and Exhibitions have been awarded in connexion with the recent medical examinations;—

SECOND EXAMINATION IN MEDICINE.—First Honours: D. J. Coffey (First Class Exhibition, £40). Second Honours: David C. Smiley (Second Class Exhibition, £20); Henry Smith.
M.B. DEGREE EXAMINATION.—First Honours: James Bradley. Second Honours: John L. Livingston, James Donelan.
DEGREE OF M.CH.—First Honours: John F. Eagleton. Second Honours: Samuel Moore, James Donelan.
DEGREE OF M.A.O.—First Honours: Cornelius Bradley. Second Honours: John L. Livingston.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The under-mentioned has been admitted a Fellow of the College:—

John Lentaigne.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 3rd inst.:—

Boyton, Edward Thomas Augustus, Wathington, Oxfordshire.
Brazil, Walter Henry, Highview, Sharples, Bolton-le-Moors.
Davis, William, Bank House, Ashford, Kent.

THE Library of the Royal Medical and Chirurgical Society will be closed on Whit Monday, (June 14th).

SANITARY PROSECUTION.—At West Ham on the 4th inst., an architect was fined £20 and costs for neglecting to connect the drains from two houses with the main sewer.

THE festival dinner in aid of the funds of the North London Consumption Hospital is to be held on the 23rd inst., Sir Henry Holland, M.P., presiding.

ON the 9th inst. Mr. Jessop, the well-known Leeds surgeon, was thrown from his carriage, receiving a severe shock and injuries to the head from broken glass.

ON the 2nd inst. portraits of its former presidents were formally presented to the Ulster Medical Society in the presence of a large assembly.

A MEETING of the Association of Municipal and Sanitary Engineers and Surveyors was held at Great Yarmouth on the 5th inst., when papers on the recent extensive sewerage improvement at Market Harborough were read.

Two hundred boys from Dr. Barnardo's Institutions will leave on Tuesday, June 15th, for Canada, under the personal care of Mr. A. B. Owen, of Peterborough, Ontario, and two experienced assistants.

WE are requested by the Committee of the Central London Throat and Ear Hospital, Gray's-inn-road (President, the Archbishop of Canterbury), to state that they gratefully acknowledge the receipt of a donation of £20 in aid of the "Llewellyn Thomas Memorial Fund" from Mr. Henry Foster Burnes, a former clinical assistant of the institution.

POPLAR HOSPITAL FOR ACCIDENTS.—The thirty-first anniversary festival of this institution was held on the 4th inst., when Sir Thomas Brassey, K.C.B., M.P., who presided, reported that the number of out-patients who had received relief during 1885 amounted to 7700, an increase of 500 as compared with the preceding year. The total receipts for the year amounted to £4810, and after payment of all expenses a balance of £1902 was left, a considerable portion of which sum has been devoted to the purchase of the freehold of the hospital. During the evening donations amounting to £1792 were announced by the secretary.

FOREIGN UNIVERSITY INTELLIGENCE.—The Austrian Government has appointed Dr. E. Neusser, assistant to Professor Bamberger, Dr. Paltauf, assistant in the Vienna Pathological Anatomy Institute, and Dr. Lustig, of the Cholera Hospital, Trieste, to study the Pellagra, which is now rife at Görtz.—The candidates for the Obstetric Chair, vacated by Professor Spaeth, in Vienna, are up to the present time limited to one—Professor Breisky of Prague.——Dr. Manuel Carmona of Valle has been appointed to the post of Director of the National School of Medicine, Mexico, vacant by the death of Dr. Ortega.——Señor Gomez Ocaña has been appointed to the Professorship of Human Physiology in the Faculty of Medicine in the University of Cadiz.——Don Maximo Tejeiro, professor in the Faculty of Medicine, Santiago, has been appointed by the Spanish Ministry of the Interior to report upon M. Pasteur's system of inoculation for hydrophobia. The Minister of War has nominated Señores Alabern and Espala on the same commission.

THE NIGHTINGALE FUND.—From the report for 1885 recently issued by the committee of this fund, it appears that the number of probation nurses admitted during the year was 45, and the number of those remaining from the preceding year was 32, making a total of 77 who received instruction. Of these, 19 resigned or were discharged, 27 completed their year's training, and 13 lady probationers and 18 nurse probationers remained in the school on Dec. 31st. The annual gratuity of £2, allowed by the regulations for the term of three years, to the certified nurses who have completed a year's service satisfactorily in some approved hospital or other institution for the benefit of the sick poor, was awarded to 71 nurses—viz., 21 for their third year, 20 for their second year, and 30 for their first year. From the opening of the school in June, 1860, to the end of 1885, a total of 833 candidates have been admitted, and 494 have left the school after completing a year's training as certified nurses. The receipts amounted to £3942, and a balance of £1829 remains in the hands of the treasurer, as against one of £2092 in 1884.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—The distribution of prizes to the students of this school took place on the 9th inst., the ceremony being preceded by the reading of a highly satisfactory report by Dr. Bruce, the Dean. The Llewellyn Scholarship of £25 was obtained by J. G. V. Sapp, who also carried off the silver medal for medicine, the silver medal for practical medicine, the silver medal for surgery, and the silver medal for practical surgery. The Golding Scholarship of £15 was awarded to P. J. Duncan, who also took the silver medal for senior physiology, the silver medal for botany, and the silver medal for materia medica. The Governor's clinical gold medal fell to E. A. Snape; the Pereira prize of £5 was divided between G. O. Richards and E. A. Snape. A. E. Baker obtained the senior silver medal in anatomy, and Charles Gibbs the bronze medal in junior anatomy, the latter also securing the silver medal for chemistry and the silver medal for practical chemistry. The silver medal in physiology was awarded to J. F. Colyer, and the silver medal in practical physiology to B. F. Jackson. For practical surgery G. O. Richards was awarded a minor surgery operating case. The silver medal in midwifery was obtained by J. S. W.

Digitized by Google

Chitty, who also carried off a similar honour in forensic medicine. J. G. H. Carter gained the silver medal in pathology, and F. M. Ludbrook and J. F. Colyer prizes in dental surgery.

MANCHESTER HOSPITAL SUNDAY AND SATURDAY FUND.—At a recent meeting of the committee of this fund it was resolved that £7000 should be distributed *pro ratâ* amongst the medical charities of Manchester and Salford. The following amounts amongst others have been paid in pursuance of this resolution:—Manchester Royal Infirmary and Branches, £2853 6*s.*; Children's Hospital, £907 4*s.*; St. Mary's Hospital, £604 5*s.* 6*d.*; Hospital for Incurables, £516 16*s.* 6*d.*; Clinical Hospital, £344 8*s.*; Salford Hospital, £372 15*s.*; Eye Hospital, £366 10*s.* 6*d.*; Sick Poor and Private Nursing Institution, £202 4*s.*; Ardwick and Ancoats Hospital, £234 18*s.*; Southern Hospital, £231 18*s.*; Lock and Skin Disease Hospital, £157 8*s.* 6*d.*; Hulme Dispensary, £99 6*s.*; Chorlton-on-Medlock Dispensary, £54 19*d.* 6*s.*; Hospital for Consumption, &c., £121 1*s.*; Ear Institution, £38 6*s.* 6*d.*; Well House Convalescent Home, £49 10*s.* In addition to the above, special contributions have also been paid as follow: Royal Infirmary, £42 6*s.* 9*d.*; Eccles and Patricroft Hospital, £26 19*s.* 10*d.*; Ardwick and Ancoats Dispensary, £24 0*s.* 9*d.*; Salford Hospital, £16 3*s.* 6*d.*; Clinical Hospital, £6 17*s.* 10*d.*; Dr. Meacham's Medical Mission, £5 0*s.* 4*d.*; St. Mary's Hospital, £5; Children's Hospital, £1 6*s.* 10*d.*; Eye Hospital, £1 1*s.*

ST. ANDREWS GRADUATES' ASSOCIATION. — The dinner of this Association was held on Tuesday evening last, when Professor J. Bell Pettigrew, M.D., was entertained in the Queen's Room of the Holborn Restaurant, Dr. Benjamin Ward Richardson occupying the chair. The company was numerous and distinguished. In proposing "Our Honoured Guest," the chairman commented on Dr. Pettigrew's excellence in various departments of medicine and science. The toast was eloquently acknowleged by the Professor, who, in the course of his speech, spoke of his work in early life, and said that his first incentive to labour came from his sister, that he went to work with a will, and won a gold medal, but that his sunshine was overcast by shadow, for in the week of his success the sister who had encouraged him to the exertion died. He briefly recounted the story of his life, and said he had kept his scientific studies free from any thought of politics. Professor Pettigrew urged upon his friends the duty of extending the reputation of the ancient University of St. Andrews, especially in a medical direction. Principal Donaldson returned thanks for *alma mater*, and a delightful evening was closed with "Auld Lang Syne," the company generally joining heartily in the chorus in the old Scottish fashion. A selection of vocal music, under the able direction of Mr. Hirwen Jones, varied the proceedings of the evening.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BUTLER-SMYTHE, A. C., F.R.C.S.Ed., has been appointed Surgeon to St. George's, Hanover-square, Dispensary.

CALEB, CLEMENT C., M.B., M.S.Dur., A.K.C.Lond., has been appointed Professor of Physiology and Pathology in the Medical College, Lahore, Punjaub.

CREGAN, WILLIAM J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Assistant Surgeon to the Liverpool Dispensaries.

DALRELL, W. R., M.A., M.B., C.M.Ed., has been appointed Head Surgeon to the Liverpool Dispensaries.

DIXON, J. R. L., M.R.C.S., L.R.C.P.Ed., has been appointed Second House-Surgeon to the Royal Southern Hospital, Liverpool, vice Dr. Knight, resigned.

FOX, W. PERCY, L.R.C.S., L.R.C.P.Ed., has been appointed Surgeon to the Warehousemen, Travellers, and Clerks' Association, Cheapside, for Clapham; and also Attending-Surgeon to the South London Medical Aid Institute.

HELME, W. CROFT, M.B., C.M.Edin., has been appointed Junior House-Surgeon to the Royal Southern Hospital, Liverpool, vice Mr. Dixon, promoted.

MITCHELL, JAMES, M.D.Roy.Univ.Irel.&L.M.K.Q.C.P.I., has been appointed Assistant Surgeon to the Liverpool Dispensaries.

MITCHELL, ROBERT, M.A., M.B., C.M.Ed., has been appointed House-Surgeon to the Dewsbury and District General Infirmary.

MORTON, EDWIN, M.B., C.M.Ed., has been appointed Resident Medical Officer to the Newark-on-Trent Infirmary, vice W. H. Bailey, M.R.C.S., L.S.A., resigned.

POPE, F. M., M.B.Cantab., M.R.C.S., has been appointed Honorary Physician to the Leicester Infirmary, vice Buck, resigned.

RODLEY, JOHN, L.R.C.P.Ed., M.R.C.S., has been appointed Head Surgeon to the Liverpool Dispensaries.

SILCOCK, ARTHUR QUARRY, M.D., B.S.Lond., F.R.C.S., has been appointed Surgeon-in-Charge of Out-Patients to St. Mary's Hospital; and Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

STEVENSON, JOHN, M.R.C.S., L.R.C.P.Lond., has been appointed Assistant Surgeon to the Liverpool Dispensaries.

STOOKES, ALEX., M.B., C.M.Ed., L.R.C.S.Ed., has been appointed Head Surgeon to the Liverpool Dispensaries.

WALKER, A. C., L.R.C.P., and L.M.Edin., has been appointed Assistant Surgeon to the Liverpool Dispensaries.

WHITE, ERNEST, L.R.C.P.Lond., M.R.C.S., L.S.A., has been appointed Medical Officer to No. 5 District of the Leeds Union.

WIGMORE, F. H., M.B.Cantab., M.R.C.S., has been appointed Senior House-Surgeon to the Royal Southern Hospital, Liverpool, vice Mr. A. H. Gordon, resigned.

WILDE, R. P., L.R.C.P.Ed., has been appointed Assistant Surgeon to the Liverpool Dispensaries.

WITHERS, J. SHELDON, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Sale and Ashton District of the Altrincham Union.

Births, Marriages, and Deaths.

BIRTHS.

BAKER.—On the 23rd ult., at Moulmein, Burma, the wife of Surgeon-Major Oswald Baker, of a daughter.

DAVISON.—On the 31st ult., at Langton House, Battle, Sussex, the wife of Rashell Davison, M.D., of a son.

DUKE.—On the 8th inst., at the Royal Military College, Sandhurst, the wife of Surgeon-Major Alex. Duke, of a son.

IRVINE.—On the 7th inst., at Royal-parade, Cheltenham, the wife of Staff-Surgeon Gerard J. Irvine, Royal Navy, H.M.S. *Volage*, of a son.

LONG.—On the 4th ult., at Agra, the wife of Surgeon J. W. F. Long, of a daughter.

MOORE.—On the 25th ult., at Naini Tal, Bengal, the wife of Surgeon-Major J. H. Moore, of a son.

MORISON.—On the 4th inst., at Victoria-street, St. Albans, the wife of J. Morison, M.D., of a daughter.

MOTT.—On the 3rd inst., at Meadowlead, Harrow, the wife of Frederick W. Mott, M.B., B.S.Lond., of a daughter.

STORRY.—On the 8th inst., at Lansdown, Stroud, Gloucestershire, the wife of Fred. W. Storry, M.R.C.S., of a daughter.

TOWNSEND.—On the 31st ult., at Benares, the wife of Surgeon-Major Townsend, Medical Staff, of a son.

UPPLEBY.—On the 4th ult., at Port Elizabeth, South Africa, the wife of J. G. Uppleby, L.R.C.P., L.R.C.S., of a son.

WHITELEGGE.—On the 1st inst., at 13, Belgrave-square, Nottingham, the wife of B. Arthur Whitelegge, M.D., of a son.

MARRIAGES.

GUTTERIDGE—PENNEY.—On the 4th inst., at Culross, N.B., Wilkins Gutteridge, M.B., M.R.C.S., of Bradford, to Mary Kate, daughter of J. Penney, of School House, Culross.

HAIRSINE—BEESTON.—On the 3rd inst., at St. Mary's, Lewisham, Hudson Hairsine, L.K.Q.C.P.I., of Roos, Yorkshire, to Cecelia Elizabeth, only child of the late W. F. Beeston, of Maida-vale.

JONES—SIMPSON.—On the 8th inst., at St. Paul's, Wilton-place, James Thoresby Jones, M.R.C.S., L.R.C.P., son of the late Rev. James Jones, and Rector of Llanfwrog, to Janet, eldest daughter of James Simpson, of Inverboyndie, Banff, N.B.

LEWIS—SHARMAN.—On the 8th inst., at St. Asaph, Christopher John Lewis, M.D., of Birmingham, to Irene Bessie, only daughter of the late Malim Sharman, Surgeon, of Birmingham.

MAC KERN—GIBSON.—On the 5th ult., at St. John's Church, Buenos Ayres, by the Rev. Austin West, M.A., assisted by the Rev. A. S. Lennox Robertson, M.A., George Mac Kern, M.D.Lond., M.R.C.S., late of Guy's Hospital, eldest son of William Mac Kern, Esq., of Buenos Ayres, to May, elder daughter of Thomas Gibson, Esq., of 1, Eglinton-crescent, Edinburgh.

PRIEST—WOOD.—On the 2nd inst., at St. Marylebone Parish Church, James Damer Priest, M.R.C.S., L.S.A., of Waltham Abbey, Essex, to Beatrice Amy, second daughter of the late John H. Wood.

STOCK—YEELES.—On the 5th inst., at St. George's, Campden-hill, John Nugent Stock, Surgeon-Major, Medical Staff, to Caroline Louisa, younger daughter of the late W. B. Yeeles, Esq., of Bathford, near Bath.

SYRÉE—WEST.—On April 28th, at St. George's, Hanover-square, W., by the Rev. P. J. Syrée, father of the bridegroom, Anton Hugh Syrée, M.R.C.S., L.S.A., of Northallerton, Yorks, to Florence Mary, youngest daughter of James Firth West, of Bonchurch, Isle of Wight.

WELLS—SAUNDERS.—On the 10th inst., at the Church of the Holy Trinity, Cuckfield, Sussex, by the Rev. T. J. Mount, M.A., Vicar, A. E. Wells, M.D., of Cuckfield, eldest son of A. J. Wells, Esq., of Cardiff, to Edith Harriette (Dingle), eldest daughter of C. E. Saunders, M.D., of 21, Lower Seymour-street, Portman-square, W.

DEATHS.

APJOHN.—On the 2nd inst., at his residence, South-hill, Blackrock, co. Dublin, James Apjohn, M.D., F.R.S., formerly University Professor of Chemistry, Trinity College, Dublin, aged 91.

FINLAY.—On the 8th inst., at St. Colm's, Trinity, Edinburgh, William Finlay, M.D., F.R.C.P.E., aged 72.

MASON.—On the 5th inst., at Brook-street, Grosvenor-square, Francis Mason, F.R.C.S., Surgeon to St. Thomas's Hospital, aged 48.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE ILLICIT SALE OF ERGOT.

How far it is fair to connect Rome's abnormally heavy infantile mortality with her large celibate population is a question we leave to others; but there is no doubt that coincidently with this mortality within her gates attempts to procure abortion have been frequent enough to call, from time to time, for the interference of Government. Under cover of an admonition to certificated pharmacists and midwives the Prefecture has issued a circular to the syndics of the City and Province to see to the strictest enforcement of the regulations as to the sale of ergot of rye. The drug, it seems, is in such request that, according to the *Opinions*, one and the same medical prescription is unlawfully used for its purchase over and over again, and this in spite of the pontifical regulation of Nov. 15th, 1836 (still in force), which requires, under heavy penalties, all chemists and druggists to retain the prescription once it has been made up, and only give to the purchaser a receipt for the money he has paid. "The Prefect has, therefore," says our contemporary, "with his circular of May 27th invited the syndics to caution all pharmacists and midwives that if they violate the above regulation they will be denounced to the judiciary authorities for criminal proceedings, and that, if convicted, they will incur the severest penalty of the law."

P. A. S. had better communicate with the author mentioned.

"IODOFORM SPRAY."

To the Editor of THE LANCET.

SIR,—It is a common saying, "There is nothing new under the sun," and the employment of iodoform in the form of spray is by no means new. If Mr. Mundie will kindly refer to my work, "On the Inhalation Treatment of Diseases of the Organs of Respiration," he will find that the use of an ethereal solution of iodoform in the form of spray is specially referred to, and some of the diseases of the throat and lungs enumerated in which the employment of iodoform is indicated.

I remain, Sir, yours faithfully,

Lucerne, June 7th, 1886. ARTHUR H. HASSALL, M.D.

To the Editor of THE LANCET.

SIR,—In your last issue Mr. Mundie recommends the use of the iodoform spray in throat and other cases, being struck with its superiority to other preparations. I was led to the same conclusions by my own observations (*vide* THE LANCET for the year 1884). Mr. Mundie will find the method of preparing the spray as there described worth a trial. When ether is objected to the following is good:—℞ Iodoformi præcipt., 3ss.; tr. senegæ, 3j.; terebene et adde aquam ad 3j. This furnishes a serviceable lotion or spray, and the odour is rather pleasant.

I am, Sir, yours faithfully,

Charlwood-street, S.W., June 7th, 1886. ALFRED LEACH.

A MEDICAL MISSIONARY FOR QUEBEC.

THE editor of the *Edinburgh Medical Missionary Quarterly Magazine* (the Rev. J. Lowe, F.R.C.S.E., George-square, Edinburgh) publishes the following extract from a letter from Quebec. He has written for further particulars, and will supply information when it arrives to anyone desiring it. A stamped and addressed envelope should be enclosed.

"In writing you at present one of my objects is to try and interest you in a work which we have in hand here, and I am sure when I state it you will grant my request. My predecessor, the Rev. D. Marsh, is the president of a cottage hospital, founded twenty years ago, for the use of the Protestant poor, for which we may soon require the services of a young medical man of good parts to work as a medical missionary. He would have rooms and board and a small salary, and would also be free to take outside practice. If my memory be true to me, you are, I believe interested in the Edinburgh Medical Missionary Society, and might be able to help us in getting a suitable man for Quebec. Of course, he must be fully qualified, and have practised for a time. We need also a Christian woman at once as matron and nurse. She would receive a fair salary, and have a comfortable home. She must not be over forty, self-possessed, sympathetic, and an active Christian worker. For such a person we ask God. I am asked to ascertain what prospect there is of getting help from your city. The cottage hospital is the only Protestant one in the place, and is endowed."

Stand Sure.—If the case progresses satisfactorily, the patient may return to work in about a month.

An Old Army Surgeon has not enclosed his card.

COCAINE IN PARTURITION.

To the Editor of THE LANCET.

SIR,—I have lately been using cocaine in parturition with such, to me, surprisingly excellent results that I think it would be a good thing for parturient women if, by means of your valuable journal, it could be brought into more general use in midwifery practice. The manner in which I use it is by applying a combination of the alkaloid with vaseline and glycerine, as follows:—Of cocaine six parts, of vaseline twenty-four, and of glycerine twenty, introduced into the vagina with an ordinary glass female syringe, passed as high up behind the cervix as possible (the glycerine is used to make the application by means of the syringe more easy). The pain due to pressure, the dilatation of the cervix, and the expansion of the perineum are so markedly relieved that the ordinary labour is robbed of half its agony. The relief from pain afforded by cocaine saves the strength of the mother, and so enables and encourages her to bring more voluntary power into play, which, with the lubricating effect of the vaseline, materially shortens the duration of the labour. Cocaine was, I find, used in midwifery two years ago, though, I believe, a solution was then applied per speculum, and I am not under the impression that I have made a new application of this valuable drug. But I claim for this compound the following advantages: it is easy of application, and can be used without the patient's knowledge, if wished; by mixing with vaseline it is applied more thoroughly to all parts of the vaginal canal, and also kept in contact therewith, ensuring a more lasting effect than when applied in solution.

I must ask you to let the great benefit of the application of cocaine in this so universally practised branch of our profession be my excuse for again bringing this subject forward.—I am, Sir, yours truly,

Chiswick, W., May 26th, 1886. BERNARD F. HARTZHORNE.

THE "PENDJEH SORE."

To the Editor of THE LANCET.

SIR,—In your issue of April 10th, p. 703, there is a description of what is called the "Pendjeh sore," from the *Vrach*, by Dr. Suski. His description exactly coincides with the characteristics of a sore very common in this part of the world, and which is, I believe, well known all along the north-west frontier of India under different names. At any rate, it seems undesirable to adopt the Russian doctor's name for it when it is so well known to most of the doctors in the Indian Medical Service who have served on the frontier of Afghanistan. Dr. Suski has some faith in applications such as corrosive sublimate and mercurial ointments; but I have never found these of the slightest benefit. So far as I have been able to make out, the sore appears to be due to a low organism, which, after getting into the skin and causing a sore, attacks the healthy skin around, advancing very slowly and forming small nests, like lupus non exedens, around the margin. The only treatment which did any good in my cases was the free application of nitric acid to the infecting sore until a healthy surface was formed, at the same time opening the small surrounding nests with the point of a lancet, and putting a tiny drop of the concentrated acid into the wound. Nitrate of silver was quite ineffectual. Dr. Suski, I think, misses an important point when he omits to mention that when these sores have existed a long time they have a permanent dull brown stain, which, together with the cicatrisation, the cachexia produced by residence in an unhealthy country, and the irregularity of the distribution of the sores might perhaps be mistaken for syphilis, especially among soldiers.

I remain, Sir, yours obediently,

A. PIERSON,
Surgeon, Indian Medical Service.

Bolan Pass, Beloochistan, May 12th, 1886.

"DIET FOR GOUTY SUBJECTS."

To the Editor of THE LANCET.

SIR,—Kindly allow me to offer the following suggestions to a brother subscriber, who, in your issue of May 29th, p. 1055, describes himself as "a martyr to gout and corpulency," and who has tried "Banting" and a vegetarian diet, and failed in each to obtain the desired relief.

I may premise what I have to say by first stating that I believe gout, rheumatism, obesity, and dyspepsia, with all their consequent ills, depend not so much on the quality of the food taken as upon the amount consumed in relation to the amount of exercise performed. The majority of the English upper and middle classes no doubt eat and drink more than is required for the perfect nutrition of the body, which in consequence becomes too plethoric; its assimilating powers are overtaxed, and there is a strain upon the excretory organs to get rid of the surplus materials which tend to accumulate in the system, leading to biliousness, gout, rheumatism, gravel, piles, &c. The obvious remedy for this consists in limiting the amount of food and drink taken, so as to strike a balance between the bodily wants and the demands upon them. Supposing, however, that, owing to the nature of a man's vocation, to his bodily or cardiac weakness, or to many other causes which might be mentioned, he is unable to maintain this balance, the question arises, in what way may he be helped with the least inconvenience to himself to get rid of the surplus matter, and thus relieve the system from what must, if allowed to remain, prove a source of disease. The remedy for this is to be found, in my opinion, most effectively in the *natural* aperient mineral waters, which, if judiciously taken, seldom fail to bring about the desired effect. The method of taking them will, of course, depend upon the individual case. An acute disease, as a rule, requires a quick remedy. Thus, after an aldermanic dinner a purgative dose, with the addition of an equal quantity of soda water, taken before breakfast the following morning, will soon set matters right. But, I presume, this is not what is required by your correspondent, and I should advise him to take every second or third morning a dose of mineral water just sufficient to act as a slight aperient. This will relieve the whole intestinal and portal systems, correct the acidity so apt to exist with gout, get rid of the tendency to corpulency, make exercise a pleasure instead of a labour, and so directly and indirectly get the whole system into such a state that life may be said to be enjoyable. At the same time, only such diet should be taken as is found to be best digested, and, as a rule, unless taking more exercise than usual (as during a walking tour) malt liquors and wines should be avoided, or indulged in very moderately, the best stimulant in such cases being undoubtedly old whisky freely diluted. Trusting these few remarks may be of value, I remain, Sir, yours very truly,

June 2nd, 1886. M.D. LOND.

Mr. A. Dix.—We regret we cannot comply with the request, as there appears to be no special novelty in the arrangement.

"A MODIFIED MIDWIFERY FORCEPS."

To the Editor of THE LANCET.

SIR,—I read with much satisfaction Mr. James McMunn's account of his modified midwifery forceps in THE LANCET of May 29th, p. 1024, and have no hesitation in saying that in one particular the idea there enunciated is a step in the way of meeting a felt want. I refer to the hinge whereby during application the handle of the upper blade is turned upwards, and so does not come in contact with the bed. In proof of my statement I may mention that it was my intention when next in Edinburgh to consult with an instrument-maker as to how this very modification could be applied to Simpson's long forceps. It is easy to say, "Get your patient's hips well over the edge of the bed, and you will have no difficulty in introducing the upper blade." Of course not; but to do so some assistance is required. Such assistance is not always easily got, as those only know who have had experience of difficult labours in country places. If the woman happen to be in that abomination, often found in Scotland, called a "box bed," the difficulty is increased. Having in view such possible contingencies, it is more than probable that the modification in question, should it turn out that by means of it the forceps can be used with ease in the ordinary position, will be hailed with delight.

I am not quite sure that I agree with Mr. McMunn in his remarks about axis traction. I have always found that Simpson's long forceps can be made to effect traction in the proper direction. Then, again, I am not sure that it is any advantage to have the blades separated at their proximal extremity. For where is it that undue pressure is generally found to have been exerted on the child's head? Undoubtedly over the forehead, and perhaps the eye. By separating the blades at their proximal extremities, unless the handles be well tied together, there is more danger of undue pressure distally. I shall conclude by saying that though Mr. McMunn has anticipated me in this matter, I bear him no grudge in consequence.

I am, Sir, yours faithfully,

Crieff, N.B., June 4th, 1886. ALEX. THOM, M.D. Edin.

"A ROUGH-AND-READY MEDICAMENT."

To the Editor of THE LANCET.

SIR,—After reading Dr. Charles H. Ralfe's letter in your last issue, I have no doubt that I quoted Druitt's Surgery inaccurately, and that the shock from which Marshal Lannes suffered was the result of a fall, and not of exposure to cold. I was writing from memory, having no edition of the above work by me.—I am, Sir, yours obediently,

June 8th, 1886. A SURGEON.

A CASE OF ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—Angina pectoris is a symptom which so rarely occurs in the ordinary routine of a general practitioner's work that I venture to report the following case *in terrorem*.

A short time ago I was summoned to see a gentleman, aged sixty-five, who looked perfectly healthy. The history of the case was as follows:—At 4 A.M. the patient had been aroused by a severe pain in the chest. He took whisky, which relieved him, and he slept again. A second time the pain awoke him, when he again resorted to the whisky, which acted as before. At 12.15 A.M., when I saw him, he complained of a diffused pain over the chest, the idea conveyed to my mind by his manner being that it was indigestion, nothing more. He mentioned that he had never had it before, was not affected by food or exercise, had no cough, breathlessness, palpitation, &c. The impulse of the heart was regular and soft, the sounds faint; the rate was normal, as was also the condition of the radial and temporal arteries. There was no œdema of the legs, and the patient had never spat blood. I ordered a mixture for dyspepsia, and left. At 5 P.M. I was suddenly recalled, and I found that the patient had been dead half an hour. He had died quite tranquilly, while reading a newspaper. The post-mortem examination showed the heart to be large, friable, flabby, and pale, with masses of fat on its surface. Both cavities were empty; there was no valvular disease, and no evidence of atheroma anywhere. I should have mentioned that the face, neck, chest, and the arms down to the elbow were deeply stained with venous congestion.

I do not cite this as a remarkable case; but the question arises, How many of the innumerable cases of pain in the chest are due to angina? The patient in this case had consulted numerous physicians, and they had all told him that the heart was all right, and that the pain was due to indigestion. It must be remembered that I had no time for watching, and that this (so far as I know, though it was contradicted at the inquest) was his first attack. I will not go into the question of differential diagnosis, as that is well known—at least, theoretically. I can only say that in future I shall be cautious in giving a definite opinion within a few days in cases of pain in the chest.

I am, Sir, yours obediently,

June 7th, 1886. J. RUSSELL HARRIS, M.D.

T. C. M.—The employment of artificial heat would appear to be of great service in the treatment of myxœdema. The temperature of the apartment should not fall below 66° F. Turkish baths prove beneficial sometimes, and also the use of infusion of jaborandi.

An Old Assistant.—A society of the kind referred to by our correspondent was founded a few years ago, of which Mr. Radley, Wynne-road, Brixton, is the secretary.

THE POISONOUS EFFECTS OF COCAINE TAKEN INTERNALLY.

To the Editor of THE LANCET.

SIR,—I should be glad if you could allow me space in your journal to relate a case which I have met with lately in my practice, in the hope that it may lead to an expression of opinion on the subject by anyone who has met with a case of poisoning by this new and useful medicine.

A patient of mine who was suffering from toothache, resulting from a hollow tooth, applied some of the 4 per cent. solution of hydrochlorate of cocaine to the tooth and gums. He did not spit it out, but, according to his statement, he swallowed from twenty to thirty drops. Within half an hour he was seized with a feeling of faintness and giddiness; then an attack of palpitation of the heart came on, and he complained of tingling and numbness, dryness at the back of the throat, and a sensation of heat and flushings moving over the body, but especially over the spine; suddenly a rash-like scarlatina made its appearance over the body, but was more marked on the neck; the pupils were natural, and responded to light, but vision was somewhat dimmed. I immediately gave him a strong dose of mustard and warm water, which did not cause emesis. I then administered twenty grains of sulphate of zinc, but without effect; it was only by frequently repeating the dose that vomiting took place. The patient was relieved for a few minutes, and seemed brighter; but the symptoms soon returned, and he felt so weak that he thought he was dying. I held some strong ammonia to his nostrils, but he said he could not smell it. I kept walking him about, but his legs tottered so much that I had to support him. He constantly felt a desire to have the use of his bowels and bladder. The mind remained clear, and the pulse became fast, weak, and intermittent.

From the above case it would appear that the symptoms of cocaine poisoning are a feeling of faintness and giddiness, palpitation of the heart, dimness of vision, diminution of the sense of smell, difficulty in producing vomiting, relaxation of the sphincters, scarlet rash, numbness and tingling, dryness of the throat, with sensations of heat up the back.

I am, Sir, yours faithfully,

June 1st, 1886. JAS. LESLIE CALLAGHAN, L.R.C.S.I., &c.

Mr. W. B. Wallis.—The correspondence does not show that Dr. Hunt intended any neglect of the patient. His own letter indicates that he did not. It would have been better, judging from the actual event, if he had acted for the absent medical attendant; but we are satisfied he intended what was right and kind.

L. L.—Certainly, though it is not usually advisable to do so.

Mr. Kersey.—We are unable to advise our correspondent.

Ingleby Lectures
ON
SOME FUNCTIONAL DISORDERS OF FEMALES.

By WILLOUGHBY F. WADE, F.R.C.P.,
SENIOR PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM.

LECTURE II.

(*Concluded from page 1106.*)

BEFORE proceeding to consider some of the details of this subject, let me ask your assent to certain postulates of a general character. These will serve the useful purpose of helping in the differentiation of hysterical cases one from another. Let it be granted, then—1. That any nerve-centre (that is, any collection of grey nerve-matter) may have its excitability exalted, so that it becomes unusually responsive to its accustomed stimulus. 2. That any nerve-centre may have its excitability lessened, so that it becomes less than usually responsive to its accustomed stimulus. 3. That the permeability of any part of the nervous system may be increased. 4. That the permeability of any part of the nervous system may be diminished. 5. That increased permeability may cause ganglia to co-operate which do not usually do so; that is, that excitement of one ganglion may excite the action of other ganglia which under other circumstances it would not excite. 6. That diminished permeability may have the contrary effect, so that ganglia which usually act consentaneously may cease to do so. 7. That any one or more of the cerebral ganglia which usually co-operate may be thrown out of gear, so that it, or they, cease to co-operate with the rest. 8. That the ganglia not thrown out of gear continue to co-operate as usual. It may be that nerve trunks have their sensitiveness or excitability increased or diminished. I do not propose either to deny or to affirm that this is so. The result would be the same as if the centre with which they are connected were affected.

Let us turn now to the consideration of some diseases commonly termed hysterical; and, first, to a common form of hysterical paralysis. The patient has lost almost completely the power of moving one or more limbs—almost but rarely quite completely, for I can recollect only one case in which no power of movement remained. The motions which do remain are, although extremely limited in area, yet often of considerable complexity. Such a paralysis, though remaining constant for weeks or months, or even years may yet disappear in an instant under the influence of sudden and violent mental emotion—such as, for example, an alarm of fire. Hence it has very properly been termed functional, as distinguished from organic. How are we to interpret this curious phenomenon? It was long ago suggested that we should look upon it as a paralysis of "the will," and this view is still pretty generally current. Without raising abstruse metaphysical questions, I fancy that, in speaking of the "will," we commonly include two separate and distinct ideas—one, the idea of a wish to do something, and the other, of our power to give effect to that wish. If we consider "paralysis of the will" by the light of this analysis, we come to this result: firstly, that in regard to the second idea, it is a mere clothing, in pseudo-scientific phraseology, of the fact that the patient has lost the power of voluntarily moving her arm or her leg. It contains no explanation of this fact, and therefore conveys none. It is, in short, a meaningless phrase. Secondly, as regards the first idea, it is untrue in fact. These patients, so far as I have been able to understand them, have a very strong wish to be able, and are deeply distressed by their inability, to move the limb. They are also extremely grateful to us when we have cured them. To arrive at a more adequate interpretation of these cases we must go some way round and consider subjects which may at first sight appear remote. Nature is in some cases not content to leave the activity of a nerve to be regulated by the greater or less amount of force emitted by its ganglionic centre. A second nerve, arising from a different centre, is told off to diminish or even arrest its action. Such superior nerves are called, as you know, "inhibitory" nerves; and the control which they exercise is called "inhibition." It is not difficult to perceive that this method is employed in the highest departments of the nervous system as well as in the lower ones. We find evidence of this operation in connexion with the high cerebral ganglia, the organ of the mind as we call it. In the passage, "Thou shalt renounce, thou shalt renounce, thou shalt renounce—this is what the whole world is hoarsely crying to thee," "inhibit" might be substituted for "renounce" without any alteration of the meaning. An inhibition of this kind, which at first requires a voluntary effort, acquires by frequent repetition an involuntary or automatic character. Most of us can see a desirable object in the possession of another without any nearer approximation to an intention of annexing it than is contained in "I wish I had one like it." In the child this inhibitory power is at best but latent, and requires for its development moral and social education. In some children it is difficult to develop it, even when the reasoning powers are indirectly stimulated by irritating applications to the peripheral nerves distributed to the skin covering the gluteal muscles. In some few it appears to be absolutely non-existent; we hear of individuals in whom the reflex act of taking is, all their lives through, the inevitable result of the act of seeing a desirable object. Some little mass of grey or some slender thread of white nerve-tissue is awanting. The same thing is seen in some savage races, who are incurable pilferers. We find in another set of circumstances something even more directly bearing upon our subject. We have most of us, at some, now probably remote, period of our lives, ran up to a hedge with the intention of jumping over it, but, "not liking the look of it," stopped short, without making a spring. This is a rational and intelligent act, though it may afterwards be evident that it was a mistaken one. We have, also, similarly ran up and made a spring, but, at the same moment, allowed the principle inelegantly called "funk" to intervene, with the result of inhibiting our muscular action, and thereby "bringing us to grief"; while a second, more confident—that is, an uninhibited effort—has carried us safely over. The secret of what is called "Dutch courage" lies, partly at all events, in the fact that one great effect of alcohol is to relax or paralyse inhibition. To this, mainly, is to be attributed the loquacity of intoxication; and so is the proclivity to the committal of crimes by persons under the influence of alcohol. Examples of the higher forms of inhibitions are common among animals; most of the tricks taught to dogs depend upon it. The exertions of a horse who has on some previous occasion been severely flogged are, in some cases, inhibited by his hearing the sound of a whip raised to strike him.

Let us now turn to an entirely different class of phenomena. Under certain circumstances, those parts of the nervous system which usually, and for useful purposes must, act in concert, cease to co-operate, one portion remaining active, while another portion is in a state of suspended animation. This is what happens spontaneously in sleep-walkers. A similar condition is producible artificially by means of mesmerism, hypnotism, and the like. In some instances there has, no doubt, been fraud and imposition practised by unscrupulous performers; but the most liberal abatement having been made on this score, there remains a series of facts of the most interesting description. If you or I were told that we could not lift from the table a pocket-handkerchief because it was so heavy, we should at once confidently proceed to show that we could. Why? Well, to put it shortly, because we should believe our experience and disbelieve what we were told. But if a hypnotised person were told the same thing, he would be unable to lift it. Why? Well, again, to put it shortly, because he would believe what he was told, and would be unable to correct the statement by reference to his experience, in consequence of some portion of his brain being out of gear. And something like this, I submit, happens in hysterical paralysis, in which, on this theory, the primary cause would be, not deficient, but excessive nerve-action. Muscular action is inhibited by the belief that it is impossible. A principle element of cure, then, is to convince the patient that her belief is erroneous. It is not easy to do this directly, for it is notoriously difficult to remove any belief by the mere assertion that it is erroneous, or even by argument. Such a course, indeed, is likely rather to strengthen than to weaken a belief. In

Digitized by Google

these cases a little benevolent trickery, or pious fraud, is often successful, as in the following case.

A young girl was brought by several friends to the General Hospital when I was house-physician. The whole party was in a state of great lamentation and woe. It appeared that the girl had lost the use of her left arm an hour or two before; the same thing had happened on two previous occasions, and the medical man who had attended her had, so they stated, told her and her friends that a third attack would be certainly fatal. Feeling, after examination, pretty certain of the real nature of the case, I pacified her by saying that, although it was no doubt a serious matter, there was every probability that she would not die, and even good hopes that she might recover the use of her arm. She was taken in and sent to bed. It does not do to pooh-pooh these cases; you may succeed, but if not you lose all control over the patient, and then good-bye to any prospect of usefulness. The next morning she moved her arm a little, as she had done the night before. She was comforted by my telling her that it was a good sign that the paralysis had not increased. The following morning she again raised it to the same extent as previously. I put my finger a couple or three inches higher, and said, "Oh, but you moved it up to here yesterday"; she immediately moved it up to my finger. On the fourth day the same manœuvre was repeated. On the fifth, the same trick being repeated, she got the tips of her fingers to her lips. I said, "How much further do you want to get them?" She laughed and the case was at an end.

Another girl was brought to the hospital who had been lying in bed for eleven months with a paralysed leg. On admission, she could, by moving the foot, rotate the end of the great toe through a circle of about an inch in diameter. I need not say that even such limited motion required the action of a number of muscles, and so facilitated diagnosis. By a judicious admixture of trickery, coaxing, and firmness, she was cured, though not so quickly as the former case.

I saw, some years ago, a fasting girl. The amount of food or even water that she was able to take was incredibly small. She was never exhibited; her emaciation was amazing, and there was no ground for reasonable doubt as to her veracity. She dwindled, and died some time after I saw her.

It is difficult to resolve the problem presented to us by these cases, but I am inclined to associate them with the preceding class, and to think that they may depend upon a belief that eating is impossible. And this belief may have had originally a substantial basis. From the dangerous extreme above mentioned, we can, without any distinct break, see all degrees of inappetence up to slight anorexia or indifferent appetite. The slighter cases are undoubtedly often due to gastric catarrh, not necessarily of great severity. In saying this it is perhaps right also to say that, in my opinion, there is little difference in point of frequency of occurrence between gastric and bronchial catarrhs. Gastric catarrh, though sometimes provocative of ravenous, is more commonly associated with diminished appetite. The view here suggested seems to me to receive support from the success of the method of treatment originated by Dr. Weir Mitchell. Take such a girl from her home, place her in the midst of new surroundings, of fresh faces, inspire her by confident assurance of her recovery, tell her you are going to restore her appetite by a new treatment, insist upon her taking food, subject her to massage, shampooing, rubbing, or whatever you like to call it. The effect is speedy, the result surprising. The quantity of food consumed soon becomes as remarkable for its largeness as it had before been for its exiguity.

Cases of hysteria may be usefully, if not scientifically, divided into three classes: first, the simple, genuine, or involuntary cases; second, those in which there is unconscious exaggeration; third, those in which there is conscious fraud or deception. These classes might, perhaps, be as properly described as stages, for there is no doubt the first may glide into the second, and afterwards into the third; or, in other words, there has probably been a time when a case of the third class has belonged to the first. We meet, especially in the third class, with some very curious cases; and oftentimes they are not only curious, but puzzling. For example, a middle-aged unmarried lady's-maid, precise and respectful, and quiet in manner and demeanour, as became the long and highly-valued domestic of two or three decorous and not over youthful gentlewomen, came to the General Hospital. She had been living in London, but had been obliged to leave her place in consequence of feeble health, caused by repeated attacks of "inflammation of the bowels, with sloughing of the mucous coat." Oh no! not dysentery, but inflammation of the small bowels. So she had been told by several medical men in London, whom she named, who had been called in by her mistresses from time to time. Such were her statements; and, though I cannot vouch for their truth, I saw no reason to discredit them. Her reason for coming into the hospital was that she feared that another attack was impending. After a few days, during which she insisted that she was suffering from gradually increasing pain in the abdomen, but no objective phenomena presented themselves, she said she had diarrhœa, and a few days after that she produced a liquid stool, containing some smooth-edged, flat, whitish pieces of something. We found by experiment that these sloughs could not be distinguished, microscopically or otherwise, from pieces of chamois-leather or kid-glove, macerated in water for twenty-four hours. I told her that what she had passed was not mucous membrane, but something she had eaten; and a few days after she found herself so much better that she would like to go home, and she went.

It is not much use arguing or quarrelling with these persons. What you want to do is to take the romance out of their cases—to show that so far from your thinking them remarkable, and therefore interesting, you know them to be commonplace and uninteresting. Thus I entirely checkmated a girl who pretended that her bowels had not been open for weeks. I told the mother the truth (which was that I knew it to be untrue), and got her to tell the patient that we did not think anything of it; that some people had evacuations and others had not; that there was no rule about such things. With this somewhat audacious statement—which she, of course, knew to be untrue, but could not well repudiate without spoiling her case—the patient's renewed attempts to excite interest in her case were consistently met, and she was ultimately beaten out of the field. Instead of denying her statement we accepted it as gospel, but in a way that took all the interest out of it. She kept up the pretence for a very long time; and, curious to say, although frequently watched, it was never discovered where or when the bowels were moved. I have seen other like cases. In another very curious case, an abandoned thief imposed upon the gaol authorities, and obtained a free pardon on the ground of ill-health, and so escaped a long term of imprisonment. On her discharge she was brought to the hospital, and the only thing that was real about her case was that her periods were very profuse. In the gaol, she was supposed to have copious hæmatemesis, and had been seen by the matron in the act of vomiting blood, the possible source of which I refrain from even suggesting.

On hysterical retention of urine I have only two words to say. It is very commonly the initial phenomenon, and is most useful, therefore, as furnishing the key to subsequent manifestations; and, secondly, that it is not often repeated when its treatment is left in the hands of the nurse, instead of being undertaken by the medical man.

Of hysterical vomiting I have seen several cases, and have not found much difficulty in dealing with them; but a particular course must be followed, which presents no difficulties in hospital practice, in which only have I met with these cases. In private practice it might be less easy to pursue. These cases begin with occasional vomiting two or three times a day only, or even less. As soon as you know what it is (which at first you may not) treat it with indifference. It soon becomes more frequent. In a few days the nurse will tell you that everything taken is immediately rejected. You order a teaspoonful of water to be given at intervals and nothing else, saying you are quite sure that will stay down. You will hear the next day that even that is immediately thrown up. Then you have got her. Place her flat on her back with the head well thrown back on the pillow, the neck and upper part of the chest being fully exposed. Let her swallow a teaspoonful of water, and keep your eyes steadily fixed on the throat; in a short time you will see a slight movement in the muscles of the throat. Say at once, "Don't do that again; anyone can make himself sick in that way." The attempt may be repeated, and must instantly be checked. You watch her for a quarter of an hour, and then point out to her that she is wrong in supposing that nothing can be retained. You will not be bothered by any recurrence of this symptom.

We do not see a great deal of emotional hysteria in our practice; and what we do see is rather in the middle-aged than in the young; and is, in fact, if I may be allowed the Hibernicism, not hysteria, but drunkenness. Judging from

Digitized by Google

my experience in Parisian hospitals, I should say that this phase of hysteria is more common in the Latin races than in the Anglo-Saxon. "Attacks of the nerves" seem to me also of more frequent occurrence in French than in Anglo-saxon works of fiction. In slight attacks a simple expedient is often successful, probably by diverting the patient's attention; cause her to make a deep inspiration and a full expiration; a few repetitions are followed by complete calm. Hysterical coma is a very curious condition, and is commonly in some degree connected with alcohol. It is most quickly relieved by an enema of assafœtida.

Reverting for a moment to the cases in which we are wont to recognise the existence of fraud and imposition, it is questionable whether in many of them we are not using a term not strictly accurate. Whether we should not rather regard them as examples of partial mental aberration, the result of a dominant idea, the desire for sympathy, than of intelligent, intentional, and conscious deception. It is, perhaps, a fine distinction, and, if sometimes a just one, we must admit that, in the words of the cynical Heine:

> "In case of women,
> One knows never where the angel
> Ceases, and the deuce commences."

These words are, also, apposite to another question. To what extent is there commonly in hysteria an erotic element? The answer to this turns largely on the meaning which we attach to "erotic." Amongst men of the world the interpretation would be of the grossest and most carnal character; and too many of us would, and do, accept this view, thoughtlessly, I think, and erroneously, in respect to the virginal sex in general, and no less erroneously as regards cases of hysteria. But the word has another sense not less classical, for it rests on the authority of Plato, and one which, in my judgment, is more in accord with the passive or receptive *rôle* of women in the processes of reproduction. In this sense it refers not so much to the lower animal passions—though these are not altogether excluded—but to the higher sentiments, from which spring all the graces and most of the charms which adorn the sex, and which do, as there is a physiological reason—indeed, necessity—for their doing, attract our own. In this sense there is, I believe, commonly, and in the other but rarely, an erotic element in hysteria.

The time at my disposal, and possibly your patience, are alike exhausted. Yet, even within the narrow limits I have fixed for myself, there are left many interesting and important topics at which we have not even glanced. For, indeed, to quote a brilliant writer, "La femme, vois-tu, c'est un thème inépuisable; on a beau l'étudier, on rencontre toujours de nouveau." I have desired on this, as on other analogous occasions, to remember that I am speaking, as one of themselves, to those whose duty and honour it is to apply in practice the art of medicine. But, you may object, such professions are but little consistent with the scheme and tenour of my lectures. You may think that there has been but a pitiful proportion of the bread of clinical facts to an intolerable quantity of the sack of speculation and opinion. It is true that this is so. But this has arisen, not from my forgetting, but from my remembering that we are all practitioners of medicine. Our predecessors have had, our successors will have, general conceptions, views, opinions, speculations, hypotheses, theories—choose which term you will—which did, and will, exercise an influence upon their acts. We ourselves, all of us, have them, and they influence our acts. None amongst us, indeed, are greater slaves to them than many of those who, in good faith, lay special claim to the title of practical men. Nor is this subjection to speculative views peculiar to the medical profession. The conceptions of mankind are compounded in varying proportions of truth—that is to say, knowledge; of error—that is to say, ignorance; of prejudice, of imagination, fancy, faith, wishes, hopes, fears. This strange medley produces forces which, intense and far-reaching in their operations, do indeed govern the world. Take a quite recent example of practical results from such a cause. The Arab conception of paradise, and of the means of getting there, has cost us many lives and much treasure, and may yet cost us more. But we have no need to go so far afield for an illustration. There is a prevalent conception of disease, which is not explicitly stated in books, and of which in its nakedness there is perhaps no one who would not be ashamed. It embodies the unquestionable fact that there are relations between disease and that which we vaguely call debility. It is true, also, that these relations are often so intimate and direct that it is of the utmost practical importance to recognise their existence. But when this conception obtains such a preponderance in the mind that it almost effaces the distinction between disease and debility, its evil consequences are most serious. It renders therapeutical efforts injudicious, confused, timid, and irresolute. It may, indeed, inhibit them altogether. It certainly does appear to me that such an undue preponderance is, at the present day, but too widely spread, and that the practice of many is thereby unfavourably influenced. This may be so, or it may not. What I really want you to admit is that an abstract conception, difficult to formulate, except perhaps, if that can be called formulation, in the shape of a truism, does actually and largely influence practice. To put the question in a concrete form: Given a case in which we correctly recognise the existence of disease, and also the existence of debility, in what measure is our treatment of the disease to be biased by our recognition of the debility, or our treatment of the debility to be biased by our recognition of the disease? That is a reasonable question, which it is incumbent upon us to put to ourselves, and to answer. Now, in my firm opinion, the answer given, too often even in the present day, results in treatment unduly recognising the debility and unduly neglecting the disease; and there is very much in female disorders to bring them within the possibility of being affected by such views. It is unsound to think that conceptions which contain an element of truth cannot be noxious. On the contrary, it is that very fact which renders them dangerous; for it is that which makes them seductive, which gives them currency, and secures to them continued existence. The element of truth is an antiseptic which protects them against the forces of decay. It has, then, appeared to me that current conceptions of the relations between their periodical functions and the general health of women have been inadequate; that some facts have been unduly exalted, whilst others have been unduly debased; and I have endeavoured to bring this before you, in order that, in your own minds, the balance might be readjusted. In like manner has it appeared to me that there are inadequacies and imperfections in current conceptions of the female nervous system and its aberrations. And I have endeavoured to lay before you some considerations on this subject which seem to me to be of importance. At all events, what I have done, however halting the argument or deficient in coherence, I have done in good faith. I ask you to take the trouble to think about it; and then I should be the last to quarrel with anyone who arrived at conclusions different from my own. For I have been all my life an unswerving advocate of free thought, accustomed to swear by the words of no master, unless they commended themselves to my own independent judgment.

NOTES ON DISEASES OF THE NERVOUS SYSTEM.

BY W. R. GOWERS, M.D., F.R.C.P.

II.

ON THE ANTERO-LATERAL ASCENDING TRACT OF THE SPINAL CORD.

SINCE I pointed out, in the first edition of my "Diagnosis of Diseases of the Spinal Cord," that there exists in the lateral columns in front of the pyramidal and cerebellar tracts a tract of fibres which degenerates upwards through a considerable extent of the cord, several other corroborative observations have been published.[1] The tract has, moreover, been rediscovered in the developing cord by Betcherew. I have traced its degeneration in several other cases of ascending degeneration of the cord, and also in locomotor ataxy. These observations have revealed some additional facts regarding its relations and position.

The tract extends across the lateral column about two-thirds of the distance from the surface to the intermediate grey substance. (Fig. I.) It dips into the angle formed by the rounded anterior extremities of the pyramidal and direct cerebellar tracts, and it extends along the surface of the cord almost to the anterior median fissure, stopping at the anterior pyramidal tract. Betcherew could not trace it beyond the

[1] An interesting paper on the subject by Dr. Howard Tooth is contained in the current volume of the St. Bartholomew's Hospital Reports.

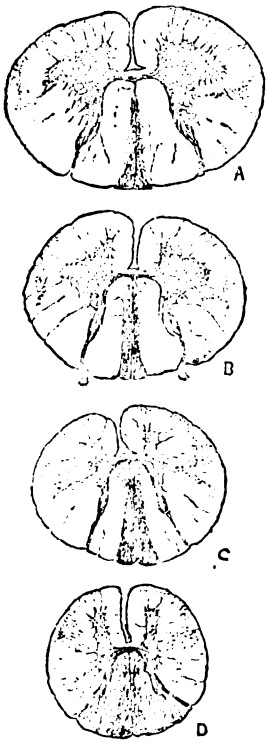

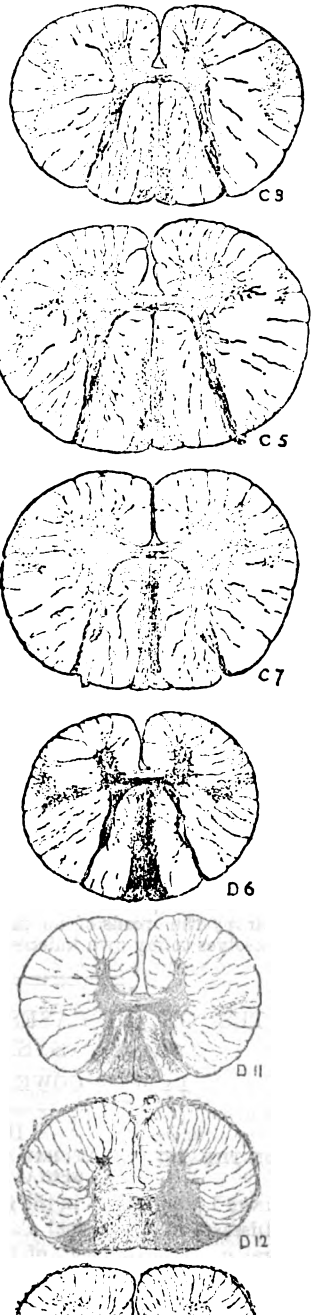

FIG. 2.

Ascending degeneration in spinal cord crushed by a fracture at the 11th dorsal. A, B, cervical, C, upper, and D, lower dorsal sections. Degeneration of the posterior median columns and of the antero-lateral ascending tracts.

this tract. I have traced it, in several cases, as far as the anterior pyramidal tract, where the sudden termination of the degeneration is sometimes very marked.[2] In the upper part of the cervical region, where the direct cerebellar tract moves forward and the pyramidal tract again comes up to the surface of the cord, a process of the ascending tract extends between the pyramidal and cerebellar tracts, and may be traced almost to the surface of the lateral column. (Fig. 2, C 3.) About the middle of the dorsal region the tract does not extend so far forwards at the surface of the cord, and in the lower part of this region the tract seems to lie only across the middle of the lateral column, opposite the posterior commissure. This arrangement corresponds with the probable course of its fibres from the opposite half of the cord through the commissure.

Sections of the spinal cord, from a case of locomotor ataxy, showing degeneration of the whole posterior columns in the lumbar region, but, higher up, only the ascending degeneration of the posterior median columns. In the dorsal and cervical region there is also degeneration of the antero-lateral ascending tracts.

It is doubtless the degeneration of this tract that has given rise to the erroneous idea that the direct pyramidal tract extends further forwards than the limit assigned to it by Flechsig from his developmental researches, and further forwards than it appears to do in other cases in which it is certainly degenerated alone. If the ascending antero-lateral tract is also degenerated, the resulting areas of sclerosis are continuous, and it is thus easy to understand how the erroneous impression has arisen. The double degeneration produces a band of peripheral sclerosis, widest opposite the middle of the cord. It is probable that this is the origin of some forms of so-called "annular sclerosis" of the cord, and also that the superficial layer of degeneration thus resulting has been sometimes thought to be caused by meningitis, an extension of the inflammation from the pia mater to the substance of the cord.

As far as we at present know, the direction in which the fibres of the central nervous system degenerate is that in which they habitually conduct. Hence the antero-lateral ascending tract conducts upwards, and there can be little doubt that in it we have the path for sensations of pain. It seems certain that these are conducted in the lateral column. The experiments of Woroschiloff have proved that the lateral column conducts the impressions that can raise the blood-pressure, and the impressions that have this effect are for the most part, if not altogether, those that, through the agency of the sensorium, are perceived as pain. The only fibres of the lateral columns that degenerate upwards through any long course are these and the fibres of the direct cerebellar tract. The latter go exclusively to the cerebellum, and it is in the highest degree improbable that they conduct any form of sensation from the skin. Hence we must identify the antero-lateral ascending tract with the sensory path in the lateral columns.[3]

I have recently had an opportunity (by the courtesy of Dr. Mott) of examining a series of sections of the spinal cord in a case in which the nerve roots of the cauda equina were extensively damaged. It is well known that where these roots are interrupted the posterior median column degenerates through the cord, just as it does if there is a transverse lesion in the lumbar enlargement. Continuity of degeneration must be taken as proof of continuity of fibre. Where fibres are interrupted by nerve cells, degeneration ceases. Hence the degeneration of the posterior median columns is proof that these fibres are continuous with some of the fibres of the posterior roots. But in the cord mentioned, in which the cauda equina was diseased, while the posterior median columns presented the usual degeneration, no trace of degeneration could be found in the ascending antero-lateral tract. Hence we must assume that the sensory root fibres, from which this tract continues the sensory path, end in nerve cells, probably in the posterior cornua of the cord. The antero-lateral ascending tract seems to be formed only in the lower part of the dorsal region. It appears therefore that the sensory path from the legs only decussates above the lumbar enlargement. I have long been of opinion, from clinical evidence, that this is so. It is not until nearly the middle of the dorsal lesion is reached that a unilateral lesion causes crossed sensory and motor paralysis. In the lowest part of this region, and in the upper part of the lumbar enlargement, a lesion on one side impairs sensation on the same side as the motor. In the medulla oblongata of a patient with locomotor ataxy, Dr. Hadden found a patch of sclerosis in such a position that it may have been the continuation upwards of the degenerated antero-lateral tract. He had not the spinal cord to examine. I am not aware that the degeneration of this tract in the spinal cord has been hitherto described in tabes. In three cases, however, I have found it distinctly degenerated. One of these is shown in Fig. 2. The fact is of interest in connexion with the frequent loss of sensibility to pain. If the above reasoning is valid, its degeneration is proof of degeneration of the sensory cells in which terminate the nerve fibres that conduct sensations of pain. It has long been known that degeneration of the cells of the posterior cornua is common in tabes; the fact was pointed out many years ago by Lockhart Clarke.

Queen Anne-street, W.

[2] The denseness of the sclerosis in degeneration of this tract may vary in adjacent parts of the same cord, probably because the short fibres ("ground bundles") of the antero-lateral column are mingled with those of the tract in a varying degree in different parts of the cord. As these fibres do not degenerate through any considerable extent, they dilute, so to speak, the degeneration of the tract, and lessen its apparent intensity in different degrees in different parts. This is probably one reason why its continuous degeneration was so long overlooked.

[3] In a case of gunshot injury to the cord which I recorded some years ago (Clin. Trans., vol. xi.) there was loss of sensation of pain, and none of touch, and the chief damage was in the position of this tract.

ON THE NATURE OF SCROFULOUS GLANDS IN THE NECK AND THEIR SURGICAL TREATMENT.[1]

BY KENDAL FRANKS, F.R.C.S.I.,
SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

I SHOULD scarcely be justified in discussing the methods of dealing with that condition of the glands of the neck which centuries have agreed in calling *scrofulous*, were I not in the first place to attempt to explain what is meant in the present day by scrofula. According to the views which we hold on this subject will our treatment depend. If we look upon scrofula in all its stages as a *diathetic* disease, then our treatment will be directed to correct this tendency; in other words, we shall have recourse to constitutional measures as the most rational—as those which promise the greatest success. If we, on the other hand, hold that scrofula is *infective*, that it owes its origin to a virus making its way into the system from without, then our treatment should in the first place be directed against the virus, to keep it out of the system or to eliminate it. Between these two modes of estimating the nature of the disease we have a third, which combines them both—namely, that scrofula is an infective disease due to a definite poison, which can only find its development, however, when planted in a suitable soil; that is to say, when it gains an entrance into the tissues of a person presenting a peculiar constitutional habit, "the greater vulnerability of parts and the greater pertinacity of disturbances," as Virchow has defined it.[2] If we accept this latter view—and recent investigations, I believe, have fully established its truth—scrofula must cease to exist as a distinctive disease, and the neutral zone between scrofula and tubercle, which has been the battle-ground of pathologists in years past, must disappear. We shall never, I suppose, eliminate the term scrofulosis, but we shall use it in a different sense from that to which we have been accustomed. In the light of the pathology of to-day we cannot accept as a definition of scrofula that it is "a tendency in the individual to inflammations of a peculiar type, the distinctive features of such inflammations being as follows: they are usually chronic, apt to be induced by very slight irritation, and to persist after the irritation that induced them has disappeared."[3] In spite of the attempts of pathologists to give a definite meaning to the term, no one will deny that the word scrofula has been used to designate most of those diseases whose pathology was a chaos of confusion, and that Henle's description of it was well merited, that "scrofula is the receptacle into which one vaguely casts all the ailments which afflict children under fourteen years, and of which we do not know the cause."[4] In discussing, then, the true nature of scrofula, it will be interesting to review shortly its history, and to trace the lines which have led to our present state of knowledge concerning it.

The term was originally given to the disease by the Romans in order "to give prominence to the similarity presented by the thickened neck, the diminished prominence of the chin, and the swelled upper lip—all consequences of the swellings of the glands—with the physiognomy of the hog."[5] In the sixteenth and seventeenth centuries the resemblance between the caseous masses found in the lungs in phthisis and in scrofulous lymphatic glands in the neck was observed, and Cullen, amongst others, began to range phthisis in the list of scrofulous diseases. "The views generally held at that period on this question," says Birch-Hirschfeld, "may be summed up in the sentence that scrofulosis reigned supreme over the domain of tuberculosis, tubercular phthisis itself being looked upon as a scrofulous disease." Laennec heralded a new epoch. Tubercle now became the chief factor, and all processes in which cheesy substance was found were classified with tuberculosis, scrofulous glands being considered only as a small subdivision of tubercular disease. But at this time little was known as to the nature of tubercle itself. The term was applied to nodules, but it had little other significance. Laennec pointed out that these nodules, originally grey and clear, had a tendency to become opaque and yellow, or, in other words, to caseate. Thus, in the lung two distinct conditions were found, the grey tubercle and the yellow, the latter being, however, the result of certain changes in the former—that is to say, the grey tubercle had a tendency to caseate in its centre, and by the fusion of several of these, larger caseous masses were formed, which went by the name of yellow tubercles. The identity of scrofulosis in the glands in the neck and of tuberculosis in the lung was then again called in question, when Virchow came forward and demonstrated that this cheesy substance was not necessarily due to decay of the grey nodules, but might occur in the most heterogeneous tissues. Tubercle was now restricted to the grey semi-transparent nodules, the size of a millet-seed, hard and firm, which have since been known as miliary tubercles; although these, from their want of bloodvessels and their low organisation, frequently tended to cheesy metamorphosis. Virchow accordingly laid down that no cheesy product was to be accepted as tuberculous unless sufficient evidence had been given of its origin from miliary tubercle. Such evidence was not at that time forthcoming in respect to the cheesy masses found in scrofulous glands; hence scrofulosis was not to be considered as a form of tuberculosis. Virchow went even further, and the cheesy infiltration of the lung, called "tuberculous" by Laennec, was not tubercular at all, but should be termed "scrofulous broncho-pneumonia." But even this position of the question was not destined to remain long unassailed. Microscopists turned their attention to the study of the so-called grey or miliary tubercle. That it was the ultimate specific cause of tuberculosis began to be doubted, as certain tissue changes, which were acknowledged to be due to tuberculosis, were found to occur sometimes, in which these distinct grey tubercles could not be discovered. In such instances the microscope revealed certain minute bodies, to which the name "submiliary tubercles" was given, and it was then shown that the millet-seed bodies, termed miliary tubercles, were made up of a collection of these microscopic nodules. This submiliary tubercle, called by Köster "primitive or elementary tubercle," is composed mainly of cells. In the centre of a typical specimen we find one or more giant cells. Forming a zone around this are many so-called epithelioid cells, and around these again is a zone of leucocytes. "All these cell elements are supported by a fine reticulum, which is generally concentrically arranged at the periphery, and towards the centre is observed to be continuous with the processes that commonly come off from the giant cells. The affected district is non-vascular."[6] This is the description of "primitive tubercle" as we understand it to-day; but it must not be supposed that this accurate histological account of it was received without much opposition. Indeed, it would seem that in its earlier days pathologists were so engaged in their conflicts concerning it that the fight over the identity or non-identity of scrofulosis and tuberculosis remained for many years in the position in which it was left by Virchow. During this period of dormancy caseous or cheesy nodules were looked upon as the products of the degenerative changes which followed on scrofulous inflammation. There was nothing specific in them. But this controversy on scrofulosis was only dormant, and it broke out with renewed vigour in the years 1865–69. A new method of attacking the question was instituted by M. Villemin. Anatomical and microscopical methods gave way to the method of inoculation, and Virchow's ground was cut from beneath his feet. These inoculation experiments showed two things, firstly, that if the cheesy matter from scrofulous glands were injected into an animal, it produced general tuberculosis as readily as tuberculous matter; and secondly, as shown by Wilson Fox, that if tuberculous matter were introduced beneath the skin, it gave rise to enlarged caseous and suppurating glands—in fact, to all the symptoms of a localised scrofula. The conclusion to be drawn from these experiments seems obvious—namely, that these local manifestations of what was termed scrofula were in reality tubercular, and that if any difference could be made out between these terms, it could only be one of degree. Such a wholesale subversion of Virchow's views, which had taken possession of pathologists for several years, could not naturally be accepted without dispute. The experiments themselves were largely discounted, and it

was maintained that, as the so-called acute general tuberculosis, which was described as following on inoculation, occurred in "animals," it was not the same as general tuberculosis in man. It now became apparent that it was more necessary than ever to understand the histological characters of true tubercle, to distinguish it from simple inflammatory neoplasms, and to determine whether the giant cell, with its external zones of epithelioid cells and leucocytes, was pathognomonic of tubercular diseases. In 1870 Wagner prepared the ground for a more accurate knowledge of the microscopical characters of these primitive tubercles, and the more complete elucidation of their differences from simple inflammatory neoplasms, made almost immediately afterwards by Schüppel, established their distinctive character. With this definite idea as to the true characteristics of tubercle itself, he proceeded to combat Virchow's views, taking for his text Virchow's own dictum that no cheesy product was to be accepted as tuberculous unless sufficient evidence had been given of its origin from miliary tubercle. This missing link was now supplied. "This demonstration," says Birch-Hirschfeld, "has been furnished by Schüppel's numerous and searching investigations to such an extent that no further doubt is left as to the frequent occurrence of well-characterised tubercles in the lymphatic glands, partly in the form of secondary development with pre-existing tubercles of other organs; partly, however, as primary tuberculosis, to which latter category belong those very conditions which have been regarded heretofore as the most characteristic products of scrofulous disease.[7] Friedländer goes a step further when he states that "all the more important scrofulous affections are intimately associated with the formation of tubercles."[8] From this period the number of diseases in which tubercle was discovered went on increasing year by year. Köster in 1869 found them in the so-called granulations in "white swelling." In 1879 Volkmann demonstrated that "white swellings" were nothing but tubercular osteo-arthritis, and that they owed their origin most frequently to a focus of tubercle in the epiphysis. In 1881 Lannelongue showed in his work on cold abscesses that the walls of the sac were studded with tubercles; and in 1883 Kiener demonstrated the identity between caries and tubercular osteitis, and showed that this specific osteitis may assume either the encysted or diffused form. The advocates of the identity between scrofula and tuberculosis seemed thus to be triumphing along the whole line, when a new difficulty arose. The giant cell, with its peculiar arrangement of cells around it, was declared not to be pathognomonic of tuberculosis. In 1875 Ziegler showed that it was found in inflammation artificially produced by inserting two little glass discs beneath the skin or in some of the cavities of the body in dogs and rabbits, and M. Martin obtained them around other irritating particles, or by introducing micro-organisms into the circulation. The question was thus again an open one, and stood thus: inoculation experiments had crowned the proof, afforded by anatomical and clinical observations, that scrofulosis and tuberculosis could not be separated, but hitherto there was no peculiarity of the structures which was pathognomonic of tubercle as a specific element. The infective nature of tuberculous and scrofulous matter alike was established, but the *materies morbi*, the virus itself, had not been recognised. Such, briefly, may be said to have been the point reached up to the spring of 1882. We all remember the sensation which was caused, not only among scientists, but in the world at large, by the announcement of Koch in March of that year, that he had discovered the bacillus of tubercle; that he had succeeded by the method of double staining with aniline dyes in demonstrating the existence of the microbe; that by cultivations on solid media he had isolated it; and that by inoculations of the pure cultivations in animals he had proved its virulence. Whatever doubts may have been at first thrown upon the discovery, whatever scepticism may have been at work to detract from it or to prove it false, all have disappeared, and there are few who to-day will deny that Koch's bacillus is the active agent in the production of tubercular diseases, wherever they are found or in whatever guise they appear. Virchow's statement that no cheesy product was to be accepted as tuberculous unless sufficient evidence had been given of its origin from miliary tubercle must now be modified and enlarged. In place of it we may assert that all inflammatory products, whether in the stage of cheesy degeneration or not, in which the bacillus of tubercle can be demonstrated, are to be accepted as tuberculous. At the same time we must remember that their absence is not conclusive evidence against the tuberculous nature of a diseased part, as in certain stages of a tuberculous mass the bacilli may disappear. What assistance this discovery has afforded to the physician, or what influence it has had upon his art, is not my object to discuss. For the surgeon it has opened up new fields of labour, and has had a most powerful influence on his work. "The sphere of tubercular diseases," writes Volkmann recently,[9] "with which the surgeon has to do has increased so enormously during the last fifteen years, insomuch as a great number of diseases with which he has to deal day by day are recognised to belong to tuberculosis, that, I say, the surgeon has now almost more to do with this disease than the physician."

Addressing as I am the surgical section of this Academy, let me call your attention to the enormous advantage which the surgeon possesses over the physician in the treatment of tubercular diseases. The diseased tissues are, or can be, exposed to view; frequently it is in the surgeon's power to remove the whole tuberculous patch, and with it the tissues in the immediate neighbourhood, while the patient still lives, and his opportunities for doing so, and the organs that are accessible to him, are increasing year by year. Now, in order to establish a disease in any organ as being undoubtedly tubercular, Volkmann[10] enumerates three conditions as coexisting. Firstly, the well-known structural condition, which has been styled "true tubercle"; secondly, the presence of the tubercle bacillus; and, thirdly, the positive results yielded by inoculation experiments. When these three conditions are verified in any diseased part, it cannot be questioned that the affection is one of true tuberculosis. This criterion has been applied to a large number of diseases, and has given positive results. I cannot now do more than enumerate a few of those diseases with which we are familiar under other names, but which henceforth must be classed as tubercular. On the skin we find lupus and certain ulcers, which have commonly been classed as scrofulous; similar conditions of the mucous membranes, and frequently fistula in ano; in the deeper structures, most forms of chronic abscesses, especially those associated with scrofulous glands, diseased bone, &c.; and in diagnosing these abscesses the so-called pyogenic membrane is of great use. "The characteristic abscess membrane," says Volkmann, "occurs only in connexion with tubercular abscesses, and it must be looked upon therefore as an absolutely safe criterion for diagnosis." All those forms of disease of the bones and joints which have hitherto been described as caries, Pott's caries, white swelling, strumous or scrofulous disease of the joints, fungous degeneration and so forth, belong also undoubtedly to tubercular infection, and the same is true whether the disease originate in the epiphyses of the bones or in the synovial membrane. Lastly, of all parts of the body in which positive proof of the existence of tubercle has been given, the lymphatic glands are most frequently engaged, because their very function exposes them to infection. Under the head of tubercle we must range all those affections of the glands which have hitherto been termed scrofulous enlargement, strumous disease, and caseous degeneration—in fact, by far the larger number of cases in which we find the glands of the neck enlarged.

LEEDS AND WEST-RIDING MEDICO-CHIRURGICAL SOCIETY.—At the general meeting of the members of this Society on the 21st ult., it was reported that during the past year the list of members has been increased by twenty-five elections, and that eight ordinary and two extraordinary meetings had been held. The following gentlemen were elected office-bearers for the ensuing year:—President: Dr. S. C. Smith. Vice-Presidents: Mr. Ed. Atkinson and Dr. Cameron. Treasurer: Dr. Clifford Allbutt. Honorary Secretaries: Mr. A. W. Mayo Robson and Dr. Jacob. Librarian: Dr. Barrs. Auditor: Dr. Braithwaite. Committee: Dr. Churton, Dr. Dobson, Mr. Wm. Hall, Dr. Hutchinson, Mr. Jessop, Dr. Fletcher Little, Mr. W. N. Price, Mr. Fredk. Shann, Dr. Swann, Mr. Wiseman, Mr. C. J. Wright, and Dr. Young.

HÆMOPTYSIS AS A SYMPTOM OF PNEUMONIA, WITH SPECIAL REFERENCE TO PNEUMONIA OF THE APEX.

BY DONALD W. CHARLES HOOD, M.D. CANTAB.,
PHYSICIAN TO THE WEST LONDON HOSPITAL, ETC.

ON the morning of April 6th, 1881, I was asked to see a gentleman staying at the Langham Hotel. I found an Italian lying on his bed, and beside him a basin in which was about half a pint of blood, which he informed me he had expectorated within the past hour. He told me that he had not been feeling well for the last day or so, and had in fact consulted Sir William Gull a few days previously. Sir William attributed his indisposition to cold. He had passed an uncomfortable, restless night, being feverish and shivery, but, feeling somewhat better in the morning, had risen as usual, with the intention of going to his business in the City. While sitting at breakfast he was seized with a fit of coughing, and found blood rising into his mouth. His handkerchief was soon thoroughly soaked with blood, and he went into the lavatory adjoining the coffee-room, and there spat up a large quantity. From the account given to me, and from the amount of blood I saw myself, he must have had severe hæmorrhage. I looked upon the case as one of ordinary hæmoptysis, prescribed some opium, and gave strict injunctions with regard to rest and quiet. I did not like to disturb my patient for the purpose of making an accurate examination, so that I cannot speak with any exactness as to the state of the chest, beyond the fact that there were a few subcrepitant râles to be heard over the subclavicular region of the left side. I was, however much struck by the temperature being high; it reached 101°; the pulse being 100. The same afternoon Sir William Gull saw the patient with me, and expressed his opinion that the case was not one of ordinary hæmoptysis, but of apex pneumonia complicated with hæmorrhage, a condition he was well acquainted with, having seen several such cases.

On examining the chest posteriorly on the left side, there was evident loss of resonance over the entire supra-spinous region; the dulness extended down to a little below the spine of the scapula, the breath sounds over this area being loud and harsh, scarcely bronchial, but abnormally distinct; vocal resonance was also increased. The following day all the physical symptoms were more pronounced, the temperature ranging between 100° and 102°. There was less blood in the expectoration, which was now more of the prune juice character. Day by day the expectoration was less coloured, and on April 12th—that is, on the seventh day of attack—there was no expectoration, and the temperature was normal. At this date, the principal, I may say the only, physical symptom was slight dulness over the upper part of the right lung, this dulness being much more marked at the posterior aspect. Within a few days the patient was well enough to leave town for the seaside, and subsequently went to the south of France.

In the spring of last year I was asked by my colleague, Mr. Frederick Durham, to see a patient upon whom he had operated for disease of bone. My opinion was asked in consequence of the patient's fever, cough, and hæmoptysis. I found a fine, strong, well-grown, healthy-looking man, an old soldier, who for ten days had been suffering from what was supposed to be catarrh. Within a few hours of my seeing him, while coughing he had expectorated blood, and I saw a spitting-cup nearly full of blood and mucus. The temperature was 102°. On examining the chest, there were marked symptoms of pneumonia, which, however, was limited to the right apex. Moreover, the physical signs of the pneumonia were more easily traced at the posterior aspect. In this case the urgent symptoms subsided within a few days, and the patient was rapidly getting well, when another attack of pleuro-pneumonia supervened, implicating both lungs, and the patient sank from exhaustion. A post-mortem examination being refused, I cannot speak with authority as to the state of the lungs. I quote the case with reference to the initial pneumonia of the apex being concurrent with severe hæmoptysis and elevation of temperature.

E. H——, aged forty-eight, was admitted under my care into the West London Hospital on Oct. 29th, 1885, for hæmoptysis. The patient was a labourer, and stated that he had been quite strong until about eighteen months ago, when he caught a severe cold, being laid up at home for six weeks. He had had a cough more or less since this attack, but had never before spat blood. On the day of admission, while walking, he had an attack of coughing, and found that there was blood in the expectoration. He lost a large quantity, and was brought into the hospital in consequence. The hæmoptysis continued after admission. He was treated by the resident house-physician in the usual manner, and, following the ordinary course in such cases, his chest was not submitted to a rigorous examination. The temperature was noted to be over 100°. Two days after admission this patient was seen by me, and I was immediately struck by the character of the expectoration, the height of the temperature, and the general aspect of the patient. On making an examination, symptoms of pneumonia were easily demonstrated. They were entirely limited to the right apex, and more especially marked at the posterior region. I made the following note at the bedside: "Right apex, front: some moist subcrepitant râles; breathing harsh. Back: decided dulness, extending to below spine of scapula; bronchial breathing above spine of scapula; a few coarse rhonchi to be heard all over the right lung." The temperature at the time of my visit was 103°, the pulse 120, the skin being hot and pungent. The patient remained in hospital for about two months, being discharged on Jan. 2nd. His right lung was not in a satisfactory condition; some dulness remained, but there were no moist sounds to be heard, and he had but little cough and expectoration.

M. P——, aged forty-eight, was admitted under my care into the West London Hospital on Dec. 4th, 1885, for hæmoptysis. He had been attending in the out-patient department for one month, suffering from cough. He had expectorated blood on two former occasions, the amount each time being small. On admission the temperature was noted as being over 100·2°, and on the following day it reached 102°. At the right apex were symptoms of pneumonia. These symptoms were much the same as in the other cases; they were limited to the region lying above and a little below the spine of the scapula. The hæmoptysis was profuse, and was seen by me. Seven days after admission the temperature was normal, and I then made the following note of the state of the chest: "At the right apex, posterior region, there is decided dulness, with increased tactile vibration, and vocal resonance. There are moist sounds, large and small, and the breathing is bronchial in character. Examining the chest in front, these physical symptoms were but slightly marked. The patient still suffers from cough, but the expectoration has decreased and is no longer blood-stained." On Jan. 28th this patient was discharged in good general health, some slight loss of resonance being the only physical symptom which was noted as evidence of the attack he had undergone.

P. Q——, aged twenty-eight, was admitted under my care into the West London Hospital on April 29th, 1885, for severe hæmoptysis. From the statements of the patient he must have lost a large quantity of blood. After admission the hæmoptysis was very profuse, and was seen by me. The temperature was 103°. The following day there were found to be marked physical symptoms of apex pneumonia. As in the other cases, these symptoms were more marked at the posterior aspect, and were limited to the upper part of the lung. The expectoration was deeply blood-stained; in fact, it was almost pure blood. Within a few days the colour gradually altered, and the expectoration assumed more the colour of that found in ordinary pneumonia, being tenacious and rusty. This patient was discharged on June 21st, about seven weeks having been spent in hospital. At the date of discharge there were signs of grave lung changes, and the pneumonic attack was evidently but the prelude to phthisis.

My desire in this paper is to emphasise the fact that in certain pneumonic conditions a sharp hæmorrhage at the initial stage is symptomatic of the attack, and is, as I believe, directly caused by the inflammatory hyperæmia. In such cases, where a severe hæmorrhage ushers in the attack, we shall find the inflammatory focus very frequently at one or other apex, and the physical symptoms of such a pneumonia are often more easily demonstrated at the posterior than at the anterior region of the chest. Such pneumonia, complicated with severe hæmorrhage, is peculiarly connected with lung tissue already the seat of chronic change, whether such change be due to deposition of tubercle or to chronic

Digitized by Google

inflammatory changes. In each of the cases quoted above there was a history of lung trouble, though in each case this trouble, as far as could be gauged by physical examination, was but small. It is a point of interest and of importance that four of the five cases were actually under observation at the time of the initial hæmorrhage. The first was under the care of Sir William Gull, who informs me that he had not detected consolidation of the apex previous to the attack of hæmorrhage; the second case was in hospital at the time of attack; and the other two patients were in attendance as out-patients. In one of these cases dulness at the apex had been noted before the attack of hæmorrhage. In each case the hæmorrhage was concomitant with a marked rise of temperature, which, I need hardly say, is not usually the case in simple hæmoptysis. In each case the rise of temperature lasted seven, eight, or nine days, and in each case, after the first day of illness, physical signs of pneumonia were easily demonstrated at the lung apex. If, as I believe to be the case, pneumonia of the apex, occurring in a lung predisposed to disease by either tubercle or chronic inflammatory changes, is liable to be complicated with sharp hæmoptysis, it will largely explain those cases of phthisis ab hæmoptæ the etiology of which appears as yet unsettled. In these cases the inflammatory disturbance which has given rise to the hæmorrhage is overlooked, and the hæmorrhage consequently regarded as the main factor in the expression. Looking at the later writers on this subject, I find that Hilton Fagge has noted the occurrence of hæmoptysis, followed by rise of temperature and subsequent consolidation of the apex, but he does not appear to have appreciated the real significance of the hæmorrhage, for he writes: "There is no doubt a *difficulty* in saying how the bleeding is brought about, but it seems very likely that the growth of tubercle in the walls of the alveoli may be attended with an invasion and softening of the coats of many of their capillaries, while at the same time the blood-pressure in them is augmented in consequence of compression of other capillaries."[1] When we think how often a lung is studded with tubercles, and how often in such cases there is no hæmoptysis worthy of the name, we must look for another cause than mere softening of the coats of the capillaries by a growth of tubercles in the walls of the alveoli. But, on the other hand, when we take into consideration the enormous hyperæmia which attends inflammation of lung tissue, a ready explanation of the hæmorrhage at once presents itself, a hæmorrhage which is concomitant with the well-known initial stage of pneumonia, the stage of engorgement. Paradoxical as it may appear, I believe that, within certain limits, the smaller the focus of inflammatory mischief the greater the liability to hæmorrhage, and this may possibly explain the fact that we find hæmoptysis a not uncommon symptom with pneumonia of the apex. Doubtless, deep-seated, concealed (as regards all physical symptoms) pneumonia is more common than is usually supposed. Clinically, I have met with several cases in which a sharp hæmorrhage has occurred concomitant with rise of temperature, and in which no physical symptoms could be discovered, at least by me. One such case I remember well. A strong, active, healthy gentleman was seized with sharp hæmoptysis after exposure to cold; there was slight fever and cough. I could discover nothing whatever in the chest. The attack gave but little real inconvenience. At the time now fourteen years ago, I looked upon the seizure as one of very grave portent. However, since then there has been no return of hæmorrhage symptoms pointing to delicacy of the chest. Another case was that of a young man aged nineteen, who was seized with a cough, fever, and hæmoptysis. I could detect no physical symptoms to account for the attack, but about seven days after the illness commenced I detected some large râles over the base of the right lung —râles, I believe, of crepitatio redux,—and I interpreted them as indicative of a small patch of deep-seated pneumonia which was undergoing resolution. This case occurred to me twelve years ago, and the subject of the attack has had good health since that date, and has no symptoms of chest weakness. Such symptoms may be explained by recognising that in connexion with a small focus of inflammation, surrounded, as indeed it must be, by a zone of intense hyperæmia, some of the gorged vessels give way, hæmorrhage results, and, as I believe frequently is the case, the patient gets rapidly well. Certainly, in the cases of apex pneumonia which I have referred to the progress was rapid as compared with an ordinary lobar pneumonia the patients were not so severely ill. May not the severity of the attack have been mitigated by the local blood-letting? It is not difficult to understand how many of these cases are overlooked as regards their true pathology. Given hæmoptysis as the marked symptom, with physician as well as laity, one of the fundamental principles of treatment is complete rest and quiet. The chest is but rarely examined beyond placing a stethoscope over its anterior surface, at most a few râles may be heard, which are explained by the presence of blood. If the temperature be high, it is accounted for by an inflammation set up by this blood. In these cases the posterior portions of the lung are but rarely examined, and I need hardly say that the apical portion covered with scapula and its muscles requires some care in examination. The dulness on percussion does not come out readily to a light tap; it requires a firm, decided stroke from the wrist; personally I find great use from a percussion hammer, and with it have found no difficulty in demonstrating the marked difference in note of the two apices when compared the one with the other.

Green-street, Park-lane, W.

A CASE OF

PUNCTURED WOUND OF THE LEFT ORBIT, FOLLOWED BY APHASIA; RECOVERY.

BY H. CAMPBELL POPE, M.D.,
AND
RICKMAN J. GODLEE, M.S.

THE following case is of interest, not only because the patient recovered spontaneously from a condition of apparently imminent danger, but also from the point of view of diagnosis, although the fact of his recovery leaves the actual lesion altogether a matter of uncertainty.

At 11.30 P.M. on Jan. 1st, 1886, about twenty minutes after the occurrence of the accident, Dr. Pope was called to see a man aged twenty-seven, who had received a stab with the point of an umbrella in the left orbit during a quarrel. He was of intemperate habits, having suffered from delirium tremens a year before, and had recently been eating very little and drinking considerably. When first seen he was suffering from shock, though he could be roused to a certain extent; he was vomiting at the time and had vomited previously; he had also involuntarily evacuated both the bowel and the bladder directly after the accident. There was a superficial incised wound along the whole length of the left upper eyelid, terminating just above the inner canthus in a circular puncture, from which a little blood was oozing. The finger was passed into this for an inch, and a probe cautiously introduced for an inch and a half in a direction upwards and slightly outwards, without striking against bone or detecting any loose fragments or perforation of the roof of the orbit. The wound was washed with water, and a pad of lint soaked in lead and opium lotion was placed over it. He was then taken home in a cab, a distance of half a mile, and on his arrival he had sufficiently recovered from the shock to be able to walk upstairs to bed, where he lay throughout the night in a drowsy condition, but vomiting at times. A little blood escaped from the nose. No paralysis of any kind was observed. On the following morning and throughout the day (January 2nd) he was perfectly sensible. The vomiting had ceased. There was considerable ecchymosis of the orbit. The pulse was 100. Three grains of calomel and five grains of powdered rhubarb were administered. But at about 8 P.M. he began rather gradually to talk incoherently, and did not recognise those around him, and this condition became more marked during the night, which was a very restless one. On the morning of the 3rd he was in a semi-conscious state, and could apparently only utter the word "Don't," and this he did only when the neighbourhood of the wound—which was now dry, swollen, and tender—was touched. The pulse was 80. A poultice was placed over the eye. He refused to take nourishment of any kind. In the course of the day the bowels acted once, and another dose of calomel (three grains) was given. By the evening the pulse was 100, and the temperature 101°. He was able to say "Don't" and "Go

Digitized by Google

away," thus having apparently gained one more phrase—that is, supposing, as we think is indicated by the sequel, his lack of words depended from the first upon true aphasia. He passed no urine, and resisted attempts to pass the catheter, so that the urine was not examined, but when obtained afterwards it was found to contain no albumen or sugar. On the 4th he regained consciousness considerably, and took nourishment for the first time since the evening of the 2nd. The following phrases were used: "Don't," "No," "Yes," "Oh no," "Go away," "I know that," "Water," "Food," "I should like." The pulse was 90 in the morning and 110 in the evening, but owing to his restlessness the temperature was not taken. Between this time and the afternoon of the 6th his mental condition improved, and he acquired several new words, but he became very irritable in temper. He slept fairly, and took the mild food which was allowed him well. At 6.10 P.M., however, he had a severe convulsion, followed by another at 6.30, and three more during the next two hours. Those which were noted began with a drawing downwards and somewhat to the right of the lower jaw, accompanied by a chuckling noise in the throat. This was followed by violent spasms, at first clonic and then tonic, of the right arm (flexors of fingers, wrist, and elbow) and leg, the left arm and leg being subsequently similarly affected. There was also twitching of the eyelids and of the muscles of the chin, but there seems to have been no marked spasm of the facial muscles generally. The respiration was hurried and groaning, and a short period of unconsciousness followed each fit. We saw him together at 9.30 P.M., when the following note was made:—The pulse was 80, soft and regular; the temperature normal. The wound was covered with a scab, and there was some swelling of the orbit, and also subconjunctival ecchymosis. The eye was in normal position, and its movements appeared to be perfect. The pupil was, like that of the other side, of normal size; it was useless to question him as to his powers of vision. There was no paralysis of the face, limbs, or trunk. The tongue was protruded straight. Sensation was apparently everywhere normal. No reflexes, superficial or deep, could be obtained; but it was not easy to test them. He apparently did not understand readily what was said to him; but he put out his tongue when told to do so, and moved to the opposite side of the bed and grasped the hand after having been asked to do so several times. He often, in trying to speak, said nothing at all, mumbling in an awkward way with the tongue. His general answer was "Yes," with a slight lisp, often repeated; or "No," uttered in the same way. He occasionally stammered out a short and meaningless sentence. He was quite unable to write. A probe passed very cautiously into the wound revealed nothing new; it passed, as far as could be judged, directly towards the position of Broca's convolution.

The question of the advisability and justifiability of any surgical interference now arose. It seemed clear, from the hæmorrhage from the nose, that some injury to bone had taken place, and most probable that the point of the umbrella had actually penetrated the left frontal lobe. It was equally evident that the aphasia depended, not on an injury to Broca's convolution or the fibres underlying it at the time of the accident, but upon some subsequent changes either arising from hæmorrhage or inflammation, and of the two the latter was thought to be the most likely cause. We considered it probable, indeed, that it depended upon some septic inflammation in the neighbourhood of the island of Reil, and that therefore trephining over the temple would not afford any chance of relief, even if the symptoms had at the time been sufficiently severe to justify such a proceeding. The wound was probed, in order to see if any loose pieces of bone could be discovered which might have been removed. It must be added that it was impossible to avoid considering the very serious medico-legal aspect of the case, though the argument derived from this view told with almost equal force both in favour of and against an operation. Ultimately it was decided to place a horsehair drain in the wound, and apply lint steeped in boracic acid solution over the eye, but to do nothing more.

On Jan. 7th the patient was more sensible. He had had four fits since the previous night, the last one being very slight. He understood better what was said to him, though still obviously muddled and very drowsy. He was less irritable, and there was slight improvement in the power of speech, the following new phrases being gained: "Fred," "Soup," "Paper," "I have no pain." In the morning he was asked to write down what he would like to eat, and apparently made an effort to write the name of a person he wished to see. In the evening, on being asked to write his own name, he wrote twice over "Mcikk." We asked him to point out the "C's" in a large advertisement of Cadbury's cocoa, when he merely tapped all the letters one after the other, muttering "Yes, yes." There was no paralysis or alteration in the size of the pupil, and no vomiting. The horsehair drain was replaced by a small drainage-tube, but there had been hardly any discharge from the wound. The œdema of the eye had slightly increased. He often put his hand to his head as if in pain, but did not complain. The temperature was 98·2°, and the pulse 80 and soft. He was given a drop of croton oil, which produced eight free evacuations, and began to take ten grains of bromide of potassium every four hours. He would not keep an ice-bag on his head. On the 8th he had five convulsions, some more severe than others—at 7 A.M., 9 A.M., 11.10 A.M., 11.45 A.M., and 2.10 P.M. After the last he was unconscious for ten or twelve minutes. The pulse was 78 in the morning and 64 in the evening; the temperature 99° in the morning and 100° in the evening. He said "Please" as a new word.—9th: After a restless night, during which the ice-bag had been applied, he became completely unconscious from 8.30 A.M. to 10 A.M., on recovery from which he was much more rational than before. At 11.30 A.M. he had a convulsion almost limited to the jaw, and followed by a very short period of unconsciousness. Four other fits occurred during the evening, and now, for the first time, marked paralysis was noticed of the right side of the face and tongue, but none elsewhere. The temperature did not rise above 99·6°. The pulse was 64, and somewhat irregular. He had acquired a new phrase, "Thank you."—10th: Two convulsions of less severity. The paralysis of the face and tongue was marked in the morning, but by the evening that of the tongue had disappeared, and that of the face was scarcely visible. The temperature rose to 101·4° in the morning, but was lower in the afternoon. The breath was very offensive. The tube, which he had pulled out, was reinserted.—11th: In the morning the temperature rose to 102°, but it fell again in the afternoon, and he became much more intelligent, saying at 3 P.M., "Is he in the house?" (alluding to his friend Dr. Patterson, who had seen him the day before); also, "Are you going to bed?" "Thank you," "Better," "I feel see" (probably meaning "seedy"), "Quinine," and "Pearson" (probably meaning Patterson). In the evening he was quite intelligent, and said he could see with the left eye. The eyelids were now less swollen. He had no convulsions.—12th: The temperature rose to 102·4° in the morning and there was some delirium, but he recognised Dr. Pope. The pulse was 80; the tongue brown and dry; but this was followed by a most marked and sudden improvement, so that at 9 P.M. the following note was taken: No paralysis of face, tongue, or limbs; answers questions quickly and for the most part intelligibly, but is sometimes at a loss for a word, when he repeats "No" several times and shakes his head as if irritated; occasionally misunderstands a question—e.g., when asked to shut his eyes he shuts his mouth; says he remembers seeing Mr. Godlee four or five times; sees with both eyes and hears with both ears; movements of the left eye perfect, but the ball is somewhat prominent; pupils small, equal, and act well to light; swelling of orbit not greater, but still considerable; drainage-tube shortened to about an inch, as there is almost no discharge; says he has no headache now, but remembers having had severe pain. Can write his name rapidly; when he attempted to do so the first time he fell back in a slight convulsion; now he falls back as if exhausted, but no convulsion follows.—13th: He is now quite intelligent and speaks well, though occasionally making slight mistakes, which he laughs at; says he has known what words he wanted to use throughout his illness, but could not pronounce them; can count fingers at three feet with the left eye. The temperature was 100·2° in the evening of this day, but afterwards did not rise above the normal; the pulse from this date was always about 70.

It is needless to specify the daily condition from this time. He remained perfectly rational and talked well, with only an occasional stumble over a long word, which gradually became less and less frequent, and at last ceased to occur. He was kept in bed till the end of January, on a low diet, and continued to take the bromide for some time. Since then he has been up and going about the house and walking outside.

Digitized by Google

He has occasional frontal headache, but principally on the right side. He talks well and reads a little, and he feeds like other people, except that he takes no alcohol. The wound has quite healed, and there is slight retraction of the eyeball.

It is useless in a case such as this, where the symptoms did not last more than a few days, to attempt to dogmatise as to the exact nature of the lesion; but it may be interesting to enter into a few speculations upon the subject. In the first place, though there is reason to believe, from the direction of the wound and the fact that there was hæmorrhage from the nose, that there was a fracture of the upper and inner parts of the wall of the orbit, there is no actual proof that there was a puncture of the brain. It is much more likely than not, however, that such was the case. In the second place, it is pretty clear that if the brain was penetrated, the loss of function did not depend upon the actual injury inflicted at the time, for the specific symptoms did not make their appearance until twenty-four hours afterwards. If we summarise the symptoms, it may be said that he presented almost complete "motor aphasia" (to borrow a definition from Dr. Gowers' excellent work on Diseases of the Brain), and that he was quite unable to write, while apparently throughout understanding, though in a sluggish way, all that was said to him. At a later period he had marked though transitory paralysis of the right side of the tongue and face, and also convulsive movements, principally involving the right side of the body, commencing with the muscles of the jaws and the upper extremity, and extending afterwards to those of the lower extremity and the other side of the body. If, then, we exclude the convulsive symptoms, about which nothing definite can be said, we may assume that those parts whose functions were interfered with were the third left frontal convolution and the lower parts of the ascending frontal and perhaps the ascending parietal convolutions, with possibly some part of the island of Reil, or else that the lesion was somewhere in the course of the fibres leading from these grey centres to the internal capsule. Now, as these parts do not appear to have been rendered functionless at the time of the accident, it is probable that this was effected either by hæmorrhage or by the extension of inflammatory mischief, and of the two the latter seems the most likely hypothesis; but whether the inflammation was of the nature of a cerebritis or a meningitis, or both, we are unable to say. It is not a little remarkable that this inflammation, though it must almost certainly have been septic, should have subsided so rapidly—indeed, that it should have subsided at all. A criticism may be made on the fact that the wound was twice investigated; but we think that this was good practice, as on either occasion it might have been possible, by removing a sharp projecting fragment of bone, to diminish subsequent risk; and on the second occasion the investigation might have led to the evacuation of some inflammatory effusion situated above the orbital plate of the frontal. When this proved impossible there was a considerable temptation to trephine the patient over the supposed seat of the lesion, and for this reason, as much as for any other, we think the case is worthy of record. Had an opening been made in the skull and some inflammatory lymph evacuated, or even merely exposed, as would most likely have been the case, and had the patient recovered, we should have no doubt ascribed to the operation a successful result which nature itself was able unaided to effect. If, however, the symptoms, instead of clearing up, had become intensified, and if the patient had become comatose, we should not have hesitated to apply the trephine, and, if no pus had presented itself beneath the dura mater, to have searched for an abscess beneath the cortex.

ANOTHER DEATH FROM WOOLSORTERS' DISEASE.—On the 7th inst., an inquest was opened at Bradford relative to the death of a man who had recently been engaged as a woolsorter, and who had just previously to his death been working at Cape mohair, which was, as he only too truly told his wife, "the wool they die on." Dr. McKenzie stated, as the result of a post-mortem examination, that deceased's death was due to anthrax, locally known as woolsorters' disease; and Dr. Hime, the medical officer of health, corroborated this evidence, and said that he considered it was of importance that fans should be fixed in the sorting rooms for the collection of the dust. The inquiry was ultimately adjourned.

A MAN'S LEG COMPLETELY BITTEN OFF BY A SHARK WHILE BATHING IN THE SEA.

RESCUE, AND IMMEDIATE AMPUTATION ABOVE THE CONDYLES; RECOVERY.

BY F. ENSOR, M.R.C.S. ENG.,
SENIOR SURGEON, PROVINCIAL HOSPITAL, PORT ELIZABETH.

THINKING that the following record will be of interest to the readers of THE LANCET, I send the details while fresh in my memory.

On January 28th of this year Mr. R——, of this town, engaged in mercantile pursuits, went with a friend to have a dip in the sea at about 7 A.M. Visitors to South Africa may remember that there are two jetties projecting from the shore into deep water, A and B; the jetty B has been only a few months in use, and, being in close proximity to the Malay quarter, offal of fish has been constantly thrown into the sea here, and hence the appearance of sharks—those monsters of the deep,—which up to this time have not been common and no cause of fear or hindrance to sea-bathers. Mr. R—— and his friend having disported themselves in their usual way, Mr. R——, who was an expert, came out of the water, and resolved to have one more glorious plunge from the deck of the jetty; on rising to the surface he felt a sharp pain in the thigh, and before he could cry out received another horrid crunch, and down he went in the jaws of a huge shark. He struggled for a moment, and felt twisted about and shaken, then free, and with an instinctive effort, as he rose to the surface, made a supreme attempt to reach the landing stairs, which were close by. There were some lads on the jetty who saw the terrible scene, and one of them stretching out his hand fortunately grasped that of the unfortunate man, and brought him to the dressing-room; those present did what they could to staunch the bleeding by ligatures of towels, &c., and a doctor and a cab were sent for. My friend, Dr. Edwards, was very quickly in attendance, and in the hurry of the moment had snatched up from his table one of, I think, Martin's elastic rubber bandages and a piece of wadding; with this appliance he quickly and effectually stopped all hæmorrhage. Poor R—— was at once conveyed to the Provincial Hospital, and when I arrived, which was in less than an hour, he was on the operating table. Pale of course, but wonderfully collected, and with a fair pulse, he consented to an immediate amputation, which was performed by the surgeon of the day, Dr. Leslie; Dr. Uppleby, the assistant-surgeon, administering the chloroform in a careful and watchful manner. The circular operation was performed above the condyles, as near to the extremity as the lacerated tissues would allow; strict antiseptic measures were adopted, excepting the spray, and a good-sized drainage-tube was inserted, not transversely, but perpendicularly, by making two incisions in the skin. This method, I think, commands better drainage. The patient bore the operation well, and on waking up asked if it was all over. A quarter of a grain of morphia was injected, and later on at night half a grain.

Next day (the 29th) the report was as follows:—The patient had slept fairly, but complained of starting and tearing in the leg; reaction had set in; the gauze was stained through; no bleeding. The dressings were renewed at 12 o'clock. Diet: barley-water, milk, and beef-tea. He was very thirsty. His mental condition was hopeful and plucky. Two silk ligatures were used to tie two large arteries, a few smaller ones were secured by carbolic gut, and the edge of the wound closed by silver wire. A minimum of blood was lost only at the time of the operation. On the 31st the dressings were renewed; temperature 99°; stump looked well; drainage good; no pus or ill odour. On Feb. 1st he slept well without morphia; temperature normal, never above 100°. From this time recovery was uninterrupted, the wound remaining quite clean and free from ill odour. The chief trouble was the irrepressible agitation of the stump while being dressed, and considerable acute pain towards evening, which the mind referred to the foot which had been torn away.

It is very rarely, I imagine, that a human being who has once been in the terrible jaws of a shark has been saved, and more rarely still saved by surgical aid. I would venture to remark that the method by which my friend, Dr. Edwards, restrained hæmorrhage is worthy of notice—the covering of

Digitized by Google

wadding and Martin's rubber bandage over the lacerated end of the femur; and the arrest of hæmorrhage was very complete. A few ounces more blood lost would have turned the scale. Would not this method be of use in cases where extremities have been torn off or crushed by machinery or by a heavy waggon? You save all blood between the ligature and the end, and avoid bruising skin, muscles, and nerves by a ligature too often applied with unnecessary force. On examination of the part removed, there were the distinct marks of the serrated edge of the shark's teeth on the outer condyle of the femur, two-thirds of which had been, as it were, sawn through; the monster must have caught the poor fellow's leg obliquely, crushed through the condyle, and wrenched the leg off, going obliquely across the joint. There were also three wounds of the skin on the same side just below the rim of the pelvis, where the shark first caught him. These healed kindly, being dressed antiseptically at the time of the operation.

March 1st.—Met Mr. R—— this morning near his house making his first essay with the crutches; he was looking well, but still troubled with pain in the absent foot. I advised him to try to do without morphia. The brain, by-and-by would cease to remember, and find it "wiser to forget."

LONDON HOSPITAL.

SEVERE URETHRAL STRICTURE TREATED BY PERMANENT SUPRA-PUBIC DRAINAGE OF THE BLADDER; REMARKS.

(Under the care of Mr. FREDERICK TREVES.)

THE following case is a very unusual one. That a patient should have had a traumatic stricture of the urethra causing difficulty in micturition for nineteen years, and for seven years dribbling of urine, and at the end of that time, when an operation is required for complete retention, no evidence of either cystitis or renal disease, is extraordinary. The treatment adopted in the case appears to have been completely successful, and the patient is now in a condition far more comfortable than that which preceded the retention. The method of treatment adopted is not by any means a usual one in traumatic stricture, and we would refer our readers to the remarks made by Mr. Treves on the case.

A man, aged fifty-five, was admitted on August 23rd, 1885, suffering from complete retention of urine of thirty hours' duration. The patient was a bricklayer, and had worked regularly till within twenty-four hours of his admission. He was thin, appeared to be in feeble health, and for a long time had felt too weak to follow his employment. He gave the following history. He had never had any form of venereal disease. Twenty years ago he fell from a scaffold and alighted upon a beam in a sitting posture, striking his perineum. A great deal of blood escaped from the urethra, and the perineum and scrotum were much ecchymosed. There can be no doubt that he ruptured his urethra. He received no local treatment. He appears to have then presented some symptoms of cystitis, which soon subsided, leaving him apparently well. Within a year of the accident, however, he began to experience some difficulty in micturition. This trouble slowly increased, and at last he was unable to pass any urine voluntarily, and it constantly dribbled away in drops. He could not keep himself dry either by night or day. For the last seven years he has worn a urinal, and has never passed urine voluntarily. For seven years his bladder has been so distended as to be visible as a tumour above the pubes. This extraordinary statement is fully confirmed by the patient's wife. He never had to discontinue his work, and he has never had any instrument passed into his urethra. He often had sharp pain in the abdomen and about the perineum. During the last eight years his wife has ceased to have children.

On admission the bladder appeared as a conspicuous tumour that reached the umbilicus. The abdominal walls were flaccid. There was no enlargement of the prostate, but there was a considerable bulging of the bladder into the rectum. A stricture could be felt through the perineum just in front of the triangular ligament, as a dense cartilage-like cord about an inch and a half long. The urine was alkaline and a trifle ammoniacal. On standing, an inconsiderable deposit of muco-pus mixed with phosphates formed. There was no more albumen than the organic deposit would account for. There was no evidence of any renal disease nor of any distension of the kidney. An examination of the other viscera gave negative results. The man's clothes were wet with urine. He stated that in spite of the urinal he had difficulty in keeping himself dry, and when in bed the urine was allowed to drip upon clothes placed to receive it. The skin about the perineum was excoriated in places, and was the seat of a slight form of eczema. No instrument of any kind could be passed, although patient trial was made. Opium and croton oil were administered and a hip-bath ordered. The result was that the urine again began to dribble away, although only in very small amount.

Aug. 27th.—Relief has only been obtained by the continued use of opium and warm baths. All attempts at passing instruments have failed. The urine dribbles away in diminishing amount, and during the last two days only when the patient is in the bath. The bladder reaches the umbilicus. The patient is much prostrated, is unable to sleep, and has lost his appetite. The temperature is normal. The bladder was punctured to-day by Mr. Treves above the pubes. A rectum trocar was used and the cannula tied in. Three pints of urine were removed.

The patient did well, with the exception that between Sept. 6th and 9th he experienced a sharp febrile attack, due apparently to hospital sore-throat. Apart from this the temperature never rose above normal. Within a few days the metal cannula was replaced by a soft rubber catheter. In the case of both these instruments a tube was attached to the free end and carried to a receiver beneath the bed, so that the bladder could be kept always empty. On Sept. 12th a soft rubber empyema tube was introduced after having been cut down to about three inches in length. This was retained by a simple contrivance of bands and elastic cords and closed with a wooden plug. The patient got up, and was discharged on Sept. 19th. At the time of his discharge the urine was acid, perfectly healthy, and free from all deposit. The patient emptied the bladder four times daily by removing the plug. He retained his urine all night. He had remained quite dry both at night and during the day. After two days' rest at home he returned to his work.

May 25th, 1886.—The patient came to the hospital to report himself. He has gained a stone in weight since September, and enjoys better health than he has known for some years past. He has followed his employment without interruption. He has passed no urine by the penis since he left the hospital. The same tube is retained, and gives rise to no inconvenience. No urine has ever escaped from the fistula, and he can now keep himself quite dry. He empties the bladder about four times daily. The urine is perfectly normal.

Remarks by Mr. TREVES.—One very conspicuous feature in this case is the fact that the bladder remained fully distended for seven years, and during that time was only relieved by the overflow attending distension. The absence of any obvious kidney trouble is worthy of note. It has been many times pointed out that in cases of chronic partial retention—as, for example, in that associated with hypertrophied prostate—the urine will remain healthy until a catheter is introduced. Every surgeon must have met with cases of enlarged prostate with persistent unemptied bladder, where the viscus has remained distended for many months and relief has been afforded only by overflow, but where no catheter has been used, and the urine passed has remained perfectly normal. With the commencement of catheterism commences the cycle of troubles that depend upon decomposed alkaline urine. In THE LANCET of April 10th, 1886, p. 722, Dr. Robinson describes a case of enlarged prostate that I saw in consultation with him. In this case the bladder had been sufficiently distended to reach the umbilicus, and that degree of distension it had maintained for at least eight or nine months. Yet no inconvenience was experienced, and the urine was quite normal. A catheter was introduced into the bladder for the first time, and since then I understand t

Digitized by Google

urine has become alkaline and mixed with muco-pus, and symptoms of cystitis have arisen. In the present patient the distension caused trouble mainly from overflow, but the urine had become unhealthy, although no instrument had been introduced, yet so slight was the modification in the composition of that fluid that it rapidly became normal without specific treatment. It would appear therefore that there is still much to learn in connexion with chronically unemptied bladder. In severe and extensive forms of stricture it can hardly be claimed that perineal section is a successful method of treatment; in hospital patients, at least, it does not commend itself. Even cases that do well for a time are practically certain to relapse, owing to the patients' neglect of the after-treatment. In the present case perineal section was the only alternative left. The state of the patient's health, the extent of the stricture, and the improbability that the man would be an intelligent party to any prolonged measures for cure, were all obstacles to that operation. As events proved, the man was not kept from his work for more than four weeks—a circumstance that could not have been contemplated had an external urethrotomy been performed. It is worthy of note that the tube has never caused the least disturbance, and that no urine has leaked out by its side, although the patient follows a laborious employment.

ST. OLAVE'S UNION INFIRMARY.

A CASE OF RECURRENT PROLIFEROUS CYST IN A WOMAN OF SIXTY-THREE; OVARIOTOMY TWICE WITHIN NINE MONTHS; RECOVERY.

(Under the care of Dr. R. J. SHEPHERD.)

ELIZABETH B——, aged sixty-three, was admitted on June 26th, 1885, suffering from tumour of the abdomen, with a history of between two and three years' duration. She was otherwise in good health. Dr. W. Beech Johnston, having been called in, confirmed the diagnosis, and also the prognosis that the case would be likely to do well. On Aug. 7th, bichloride of methylene was given by Mr. V. A. Jaynes, and Dr. Shepherd, assisted by Dr. W. Beech Johnston' Dr. Malpas, and Mr. W. Steer, performed ovariotomy with strict antiseptic precautions. The tumour consisted of two large cysts, each about the size of a cocoa-nut, and of a prodigious number of smaller cysts from the size of a pea to that of a goose's egg. The pedicle, of a good length, was tied with carbolised silk and dropped back. The operation was a very simple one; there was no difficulty, and no ligatures were required. The sutures were removed on the eighth day, and when next the dressings were removed the wound was healed. Severe tympanites occurred on the third day and gave rise to some anxiety, but the temperature did not rise. It was probably caused by reflex irritation from a tight suture, of which some misgivings had been felt, and it subsided on its removal. Otherwise convalescence was uninterrupted and the patient grew quite fat.

Early this year it was plain that the woman was again the subject of ovarian tumour. She was urged to submit to its early removal, but refused till April 19th, when she again underwent the operation of ovariotomy. The tumour was the counterpart of its predecessor, only smaller. The pedicle was longer and had become twisted on itself, so that it had to be untwisted four or five times before the ligature was placed around it. The operation was even easier than before. She never had a bad symptom, and is now well.

INGHAM INFIRMARY, SOUTH SHIELDS.

COMPOUND COMMINUTED FRACTURE OF THE PATELLA; RECOVERY WITHOUT OPERATION.

(Reported by Mr. H. BRAMWELL.)

IN his remarks Mr. Bramwell said that, having read an account of a case of this nature given in THE LANCET of May 8th, treated by suture of the patella, he was led to report the following case. It shows how little constitutional disturbance may follow such a serious injury of the parts be rendered aseptic.

[illegible] from a scaffold, the right knee [illegible] while in the flexed position. [illegible] 1885, at 5.30 A.M., there was an irregular wound over the front of the right patella, bleeding freely. The finger could be passed directly into the joint through the patella, which was divided into three portions—an upper (largest) and two unequal lower ones, that on the outer side being the larger of the two. The limb was immediately placed in a long back splint, reaching up to the gluteal fold, and the tissues of the thigh drawn downwards by two strips of strapping placed on the sides, fastening to the splint below. The limb was firmly bandaged to the splint, leaving the knee exposed, and the whole raised so as to flex the thigh on the pelvis. The knee-joint was now thoroughly washed out with 1 in 2000 perchloride solution, covered with a thick layer of salicylic wool, and bandaged with a convergent spika of elastic webbing.

March 18th.—Has passed a good night; temperature 99·8°; pulse 76; a little discharge through the dressing. Some 1 to 20 carbolic oil was poured over the part and more wool placed outside. Joint a good deal swollen.

19th.—Morning temperature 98·4°; evening 99·9°; pulse 86. Leg quite easy.

22nd.—Has been fairly comfortable; had a little pain; temperature and pulse normal; the swelling in the joint still continues. Superficial dressings removed under spray; that immediately in contact with the wound not removed, being caked with blood into a firm clot. The joint was aspirated, and about two ounces of blood-stained fluid withdrawn.

25th.—Temperature and pulse normal. Fluid has again accumulated. One ounce of fluid containing blood and a few pus cells drawn off with the aspirator.

31st.—All dressings removed; wound quite superficial; fragments are lying in good position. A little fluid in the joint.

April 6th.—Wound quite healed; the fragments of the patella brought firmly together by a spika of elastic bandage.

17th.—Complains of a "pulling pain in the knee."

May 1st.—Splint removed. The fragments of the patella are firmly consolidated together; no interval can be detected between them, and it is universally hard all over. The right patella is half an inch longer than the left. Patient can move the joint freely; much flexion not attempted for fear of breaking down the union. A stiff bandage applied.

June 16th.—Patient presented himself after being at his work a fortnight. He uses the leg freely, there being slight stiffness in the knee, only inconveniencing him when he wishes to kneel. The two larger fragments are still firmly united; an interval can be detected between the lesser and the remainder.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Hereditary Syphilis in Infants.

AT the meeting on May 7th,

Drs. COLCOTT FOX and J. B. BALL read a paper on some cases of Hereditary Syphilis in Infants in which the Bones were affected. The paper was illustrated by drawings and a number of pathological and living specimens. The latter included six infants with typical Parrot's natiform bossing of the cranial bones. The following cases, mentioned by the authors, in which the phalanges were involved, are worthy of record. Case 1: William S——, aged ten weeks; fed at the breast only; the first child; born at full time and not preceded by any miscarriage. Snuffles almost from birth; dirty pallor of skin; hoarseness; noted papular syphilides; pseudo-paralysis of right arm, which remained hanging and pronated against the side of the body. Thickening of the upper part of the right radius and ulna, causing evident swelling. Hard swelling of the proximal segment of the index-finger. Rapid improvement and ultimate cure under powdered mercury and chalk. Case 2: Albert Y——, aged eight weeks and a half; brought up at the breast only; the fifth child. Two immediately previous children died at six weeks of age with an eruption, and another was stillborn. A——, had snuffles and hoarseness from birth, and [illegible] thematous syphilide about the buttock from a [illegible] When he came under observation he had [illegible] of feet, *café-au-lait* tint of skin, and a [illegible] fingers' breadth below ribs. He was [illegible]

Digitized by Google

a great deal when touched or moved, and could only move the arms very feebly indeed, and the left leg only very little. The mother had noticed this for some time. There was swelling of the hands, chiefly visible on the dorsal aspect, and enlargement of the metacarpal bones. The digits were also swollen, and each separate phalanx on both hands was felt to be thickened, and presented to the eye a distinct fusiform enlargement. Nails normal. The left humerus and the left radius and ulna were decidedly enlarged in their lower fourths, with crepitus at lower end of left humerus. The right radius and ulna were thickened at their upper portion. Both feet were swollen, especially on the dorsum, with thickening of the metatarsal bones. The lower end of the right tibia, the left femur, and the upper end of the left fibula were thickened, and also the whole of the left tibia, especially at the lower part. A soft spot was noted at the outer and back part of the left parietal bone, and a week later a similar very distinct spot in the frontal bone, and subsequently some more cranio-tabes in the frontal about the outer angle of the orbit, which disappeared in three or four weeks. The lesions steadily subsided and the general health improved under powdered mercury and chalk, and in three months all traces of swellings and the pseudo-paralysis were gone. In the first case recorded of infantile syphilitic dactylitis—viz., Archambault's case in 1869—all the distal phalanges were involved; but in others by Bulkley, Curtis, Smith, Taylor, and Cripps Lawrence, the distal phalanges were more or less affected. The authors, whilst fully alive to Taylor's note of caution concerning the middle phalanges, determined that every one was involved in Albert Y——, so that the case is quite unique.

ACADEMY OF MEDICINE IN IRELAND.

Extroversion of the Bladder.

A MEETING of the Surgical Section was held on Feb. 19th, Dr. E. H. BENNETT submitted to the section casts of the original deformity and of its modification by Wood's operation in a case of Extroversion of the Bladder. The patient was a female, on whom the first operation was performed three years ago, when the child was a year old. Previous to the operation the urine was frequently observed to flow *guttatim* from the orifices of the ureters, the deformity being of the ordinary variety. The first operation effected the complete covering of the exposed bladder surface, but as the wounds healed a considerable shrinking of the flaps took place, and the orifices of the ureters were again exposed. After some months the urinary flow was seen to take place in irregular squirts, not *guttatim*—a condition which could only be explained by assuming the existence of dilatation of the ureters. Two operations, which consisted in the paring of the edges of the flaps, converging in the middle line, served to close the opening in which the vesical membrane was exposed as far down as the cleft clitoris. Nothing now remained but to adjust an apparatus for conducting the urine into a proper receptacle. Attempts in this direction were commenced in June, 1885, when the child was four years old, and when an interval of many months had elapsed after the last operation. At this time the child did not appear in as good health as previously, and this failure increased slowly until her illness became extreme. Her death was brought about by constant vomiting and wasting. The examination of the pelvic viscera and site of the operation proved that the cause of death was purulent inflammation of the ureters and pelves of the kidneys, with great dilatation of the ureters.—Mr. WHEELER said he had two cases eight years ago, which were of interest on the subject—one of external eversion of the bladder, and the other of ectopia vesicæ with fissure. The external eversion of the bladder occurred in a young woman aged nineteen. Her anus was put forward. She had a short narrow vagina, and the uterus could be easily felt on pushing up the finger into it. On looking at the bladder, the two ureters could be seen, which dropped urine sometimes together and sometimes alternately; while occasionally, the urine being held, there would be a squirt. He turned down a long umbilical flap, and then two pyriform flaps at each side. The flaps came nicely together. The umbilical flap fitted in by the side of those which overlapped and were brought together by hare-lip pins. For some time the case progressed favourably, but the urine trickled down underneath the flaps, and there did not seem to be retention. The side flap and portion of the anterior flap sloughed. Besides having the abdominal wall open, the anterior wall of the bladder was absent. The girl would not be operated upon again unless she was promised a cure. The second case was that of a young gentleman who had got ectopia vesicæ with a hypospadias. He made an excellent recovery following the operation, and he had a certain power of retention, though obliged to wear an artificial apparatus to catch the urine.—Dr. MILES thought the most interesting point was the dilatation of the ureters from the pressure of the flaps, and suggested that it might be overcome by the contraction of the fibres of the ureter.—Mr. STOKES said he was not disposed to adopt Wood's operation, there being such a redundancy of tissues on each side of the opening, and under the circumstances he considered two square-shaped flaps brought together over the mesial line would be sufficient. Another objection to Wood's operation in the case of adults was that the turning back, and having a hairy surface on, the lining of the membrane of the bladder might lead to troublesome consequences by the formation of phosphatic deposits, unless steps were taken first to destroy the hair.—Dr. BENNETT having replied, the section adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the Society was held on April 22nd, Mr. R. J. Pye-Smith, President, in the chair

Congenital Tumours of Orbit.—Mr. SNELL related this case, which occurred in a young woman. The tumours were subconjunctival at the outer side of each orbit. Both have been removed. The patient had also partial coloboma of one eyelid, and absence of the greater part of the external ear on one side. Mr. Atkin examined the tumours with the microscope, and described them as "mixed" tumours.

Salivary Calculus.—Dr. HARGREAVES exhibited a calculus from a man aged forty-five. It measured half an inch long and one-sixth of an inch wide. It was in connexion with the submaxillary gland, but instead of coming by the duct it ulcerated through the mucous membrane posterior to it.

Dentigerous Cyst.—Mr. GARRARD related this case. It occurred in the lower jaw.

Communication between the Stomach and Transverse Colon.—Mr. JEFFREYS (Chesterfield) showed the specimen from a man aged fifty-four, a retired publican. Pain over and enlargement of the liver were first noticed in May, 1884. Later there had been several attacks of profuse offensive expectoration, and they lasted a considerable period. Emaciation steadily increased. On Feb. 16th last he had a severe syncopal attack, and shortly after stercoraceous vomiting set in; this was preceded by severe diffused abdominal pain. He suffered a great deal from constipation, and enemata were used. On Feb. 27th he passed a large piece of necrosed tissue, accompanied by hæmorrhage. He died on March 2nd from exhaustion. At the post-mortem a large cavity was found containing pus, and extending from the lower part of the transverse colon to the under side of the diaphragm; the spleen formed the outer, and the posterior wall of the stomach the inner, boundary. The stomach, through an opening in its posterior wall, communicated with this cavity, as did also the posterior part of the transverse colon; there was also an opening (from the abscess cavity) through the diaphragm, and at this point the left lung was adherent.

Contamination of Drinking-water with Lead.—Mr. PYE-SMITH referred to the large field at present open in Sheffield for observation of the effects of the contamination of drinking-water with lead, and after quoting the opinions of various authorities as to the probable frequency of unrecognised cases of chronic plumbism in the absence of the usual pronounced symptoms, he mentioned several classes of cases he had met with where he suspected lead to have been the cause of the symptoms—namely, cases of severe functional derangement of the circulation and digestion without signs of organic disease, cases of arthralgia and myalgia, of nerve disturbance, and of abortion. All the cases referred to occurred within the area supplied by the Redmeres water, and the majority of the patients showed evidence of the presence of lead in the body by a blue line on the gums.—Remarks were made by Dr. Martin, Dr. Porter, Mr. Garrard, and Dr. Keeling.

Reviews and Notices of Books.

A Manual of Practical Therapeutics, considered with reference to Articles of the Materia Medica. By EDWARD JOHN WARING, C.I.E., M.D., Fellow of the Royal College of Physicians of London. Edited by DUDLEY W. BUXTON, M.D., B.S., Administrator of Anæsthetics at University College Hospital and the Dental Hospital of London. Fourth Edition. London: J. and A. Churchill. 1886.

Materia Medica and Therapeutics: Vegetable Kingdom; Organic Compounds; Animal Kingdom. By CHARLES D. F. PHILLIPS, M.D., late Lecturer on Materia Medica and Therapeutics at the Westminster Hospital. London: J. and A. Churchill. 1886.

A Guide to Therapeutics. By ROBERT FARQUHARSON, M.P., M.D., LL.D., late Lecturer on Materia Medica at St. Mary's Hospital. Fourth Edition. London: Smith, Elder, and Co. 1886.

Materia Medica and Therapeutics: an Introduction to the Rational Treatment of Disease. By J. MITCHELL BRUCE, M.A., M.D., Physician and Lecturer on Materia Medica and Therapeutics at the Charing-cross Hospital. Third Edition. London: Cassell and Co. 1886.

"OF making many books," saith the Preacher, "there is no end"; and this is undoubtedly true of the production of new editions of works on Materia Medica and Therapeutics. We are not sure that we might not add that such study is a "weariness to the flesh," but this might perhaps savour of ungraciousness, especially as the four works before us are all excellent in their respective ways and deserving of detailed criticism. The place of honour must be assigned, on the ground of seniority, to Dr. Waring's excellent "Manual of Practical Therapeutics," the first edition of which, if we mistake not, appeared in 1865, and the last in 1871. The present issue is the joint production of Dr. Waring and Dr. Dudley Buxton. The text has in many places been judiciously curtailed, and it is now not only a thoroughly practical work, but a capital text-book for students. The introduction, which is apparently new, is charmingly written, and is a type of all that such an essay should be. The book is from beginning to end well up to the times, and we find in it abundant information on all that relates to picrotoxine, pilocarpine, agaricin, hamamelis, piscidia, casca, cascara sagrada, tonga, extract of malt, Warburg's tincture, and a host of other drugs and preparations concerning the uses and properties of which examiners in these progressive times are apt to be inquisitive. The chapter on Coca—which we are glad to see is not spelt "cuca"—is thoroughly practical, and contains brief references, admirably digested, to nearly all that has been written on the subject. The notes on Ethidene and other anæsthetics—a word which, by the way, was introduced by Oliver Wendell Holmes—are to the point, and show the trace of a master-hand. An attempt has been made to classify the various extracts of malt according to their activity. A very able account is given of the therapeutic uses of the various oleates, frequent reference being made to the valuable observations of Shoemaker of Philadelphia. The influence of Dr. Waring's long Indian experience and extensive reading is everywhere noticeable, the work being as scholarly as it is practical. We can only repeat that in its present form it is essentially a book for students, and that its production reflects the greatest credit both on the author and the editor. The veteran therapeutist who gave us the "Bibliotheca Therapeutica" has added another leaf to his laurels, and we trust that his excellent "Manual of Therapeutics" will pass through many more editions under his care, and long maintain the high reputation to which it is deservedly held.

Dr. Phillips's bulky volume is a [illegible] and almost entirely rewritten edition of the "[illegible]," which appeared in 1874. Taken in conjunction with the "Inorganic Substances," by the same author, it constitutes a complete work on Materia Medica. It is a wonderful compilation, and is almost encyclopædic in character. If there is a fault to be found with it, it is that in places it is a little too conventional in character. Dr. Phillips, in his desire to be just to others, is too apt to sink his own individuality and to leave us in doubt as to his opinion on the subject under discussion. Such modesty would be commendable in a novice, but is uncalled-for in one who, like Dr. Phillips, has attained a high reputation as an authority on therapeutics. The whole work is divided up in a manner which greatly facilitates reference, the materials being admirably classified and arranged. The author gives such a good account of the uses of pulsatilla that we are at a loss to understand why it should again have failed to obtain a place in the Pharmacopœia. The remarks on Apomorphia—or Apomorphina, as it is now called—are practical, and indicate a thorough acquaintance with the literature of the subject. Sanguinaria canadensis receives more attention than is usually devoted to it in English works on Materia Medica, and the article will be perused with pleasure. An excellent *resumé* is given of our knowledge of Quebracho, respecting the value of which in the treatment of various forms of asthma there is still much difference of opinion. The chapter on Belladonna is excellent, and deserves careful study. The observations on Pepsin are perhaps a little unsatisfactory, and we are surprised to find that not only has no attempt been made to classify the various preparations according to their activity, but that, curiously enough, Dowdeswell's classical paper is not even mentioned. In the article on Nitro-glycerine there are several misprints, one of the most noticeable being that which assigns 1868 as the date of Mr. Field's well-known article on the physiological action of this remarkable drug. These, however, are but trivial errors, in no way affecting the general value of the work, the production of which reflects the highest credit on the author. The magnitude of such an undertaking, extending over so many years, cannot be over-estimated, and we heartily congratulate Dr. Phillips on the completion of his task. The book will have its value recognised both here and on the Continent.

It is always a pleasure to turn to Dr. Farquharson's "Guide to Therapeutics." He writes clearly and forcibly, and in a manner which commands our attention and respect. He is evidently an uncompromising opponent of the new Pharmacopœia; and, after giving a list of the seventeen omitted articles, says: "I would gladly have seen the list much more extended and made to include a large number of utterly useless articles which still linger on in our text-books, and whose reputation depends on a mysterious and unscientific catalogue of supposed virtues handed down from one generation of authorities to another. I should like to have seen a clean sweep of many of these, and must express some disappointment that official sanction has not been given to lightening the pages of our manuals of materia medica and the memory of our over-taxed student of many drugs which no one ever dreams of prescribing, and which in some instances probably could not be found if they were wanted." The arrangement Dr. Farquharson adopts is very popular with students, who find it of the greatest assistance in preparing for examinations. It might be supposed that the author, with his numerous engagements, political and otherwise, would experience some difficulty in keeping abreast of the progress of an advancing and exacting science such as pharmacology; but there is no sign of falling off, and the book is as accurate and as tersely written as of yore. The author acknowledges in graceful terms his indebtedness to his friend Mr. Carteighe, the President of the Pharmaceutical Society.

Dr. Mitchell Bruce's "Materia Medica and Therapeutics," has rapidly attained the dignity of a third edition. It contains a great deal of useful information in a condensed and practical form. We are afraid we must object to the definition given of pharmacology, which certainly does not "include the whole subject of materia medica and therapeutics," and has, in fact, very little to do with either. The account of sulphide of calcium—or calx sulphurata, as it is now called—is curiously imperfect, and no indication is given as to the best mode of administration. The definition of extract of malt and its preparation are both open to criticism, and objection might be taken to the statement that it should not be administered "less than two hours after a meal." The dose of tincture of aconite is said to be from five to fifteen minims, but no warning is given as to the necessity for caution in the employment of these massive quantities. It is stated that the hypodermic injection of apomorphina "should be prepared as required," but we are not told that this is wholly unnecessary, and that it acts equally well and promptly however long it may have been made. These are but small matters perhaps, but they are of importance. The work on the whole has been carefully prepared, and the author very properly does not confine himself within the narrow limits of the British Pharmacopœia, but gives short notes on homatropine, duboisine, strophanthus, agaricus, pyridine, and other remedies. We are glad to find that he refers to the fact that atropin can be resolved into tropin and tropic acid, and reconstructed by the synthesis of these bodies. The book is clearly written, and is sure to be popular with students preparing for the various pass examinations in materia medica.

Food and Feeding. By Sir HENRY THOMPSON, F.R.C.S. Fourth Edition, Revised and Enlarged. London and New York: Frederick Warne and Co. 1885.

Diet in relation to Age and Activity. By Sir HENRY THOMPSON, F.R.C.S. London: Kegan Paul, Trench and Co. 1886.

WE are very glad to find the publications of Sir Henry Thompson on Food questions so much appreciated and in such demand as is implied in a fourth edition of "Food and Feeding," and the separate publication of his article on "Diet in relation to Age," which appeared originally in the *Nineteenth Century*. It may seem incongruous for one of the foremost surgeons of the world to concern himself about questions of food and cookery. A man of less authority, it might seem, would have done better than to descant on the advantages of braising as compared with roasting, or to supply a few pages of *menus* for those who want to construct their dinners in a way that meets at once the demands of fashion and the requirements of physiology. But only a superficial reader of Sir Henry Thompson's writings will thus judge. For ourselves, we accept entirely his main principles, and much admire his lucid enunciation of them. We can see nothing but the most practical benevolence in Sir Henry Thompson's expositions on this subject, which, we can well believe, have originated in the peculiar experience which he has in the department of practice of which he is *facile princeps*. The main points of Sir Henry Thompson's teaching are that as a nation we are heavy in our feeding and in our ideas about it. Our notions of weakness, and the cure of it by huge quantities of meat, are as coarse as the uric acid crystals to which they lead, and which compel many men to seek the professional services of Sir Henry and his colleagues. For ourselves, we are not learned enough in culinary science to criticise the details of Sir Henry's *menus*, but on medical grounds we entirely and very earnestly endorse his teaching that we require less meat and more vegetables in our diet; that our alcohol should be greatly reduced; that the large substitution of fish for meat would be an unmixed benefit; and that as age increases and the activity of life diminishes, our food, and especially our animal food, should be correspondingly diminished. It would be difficult to over-estimate the good Sir Henry Thompson has done as a surgeon; but we are disposed to say that it is not greater than the good he is doing by his publications on the principles of diet and good cooking; and those whose duty it is to undergo the slow process of martyrdom by public dinners ought to be specially grateful to him for trying to lighten the fare both of the *menu* and the toast-list, which are seriously threatening to drive all reasonable men from public dinners.

New Inventions.

A NEW INSTRUMENT FOR CASES OF EMPYEMA.

IT is admitted at the present day that a suppurating pleural cavity should be treated on the same principles as an abscess in the cellular tissues or in the substance of an organ—viz., by free incision and subsequent free drainage. The tubes here shown were designed especially for cases of empyema. The instrument consists of a couple of short tubes, 1 in. to 1½ in. long, and ⅜ in. in diameter, welded together side by side, at one end of which is a narrow flexible plate. The length of this double tube is made to vary so as to adapt the instrument to the varying thickness of the chest wall in different cases. The method of using it is as follows:—A free incision having been made, so that the opening in the parietal pleura as well as that in the skin shall be about 1½ in. in length, and the distended cavity relieved, the instrument is inserted, and then fastened to the chest wall either by strapping or tapes attached to the flexible plate, which acts as a flange. This plate lies close to the chest wall, and prevents the tubes either slipping in or being forced out. The cavity can then and at subsequent dressings be irrigated by the "syphon" rubber tubing which accompanies the instrument, being passed through one of the openings. The discharges and injected fluid have an equally free exit through the other tube. By this method the suppurating cavity can be completely washed out without fear of distending the cavity, and thus breaking down delicate newly formed adhesions. There is no occasion to pass the rubber tubing more than one inch within the chest wall. Two large-sized rubber tubes were successfully used on this principle in a recent case; but the instrument shown in the engraving is intended to reduce many little inconveniences and some slight disadvantages attending their use. It is made in either rubber or metal, the latter being used where there is trouble or danger from approximation of the ribs. I am indebted to Messrs. Arnold and Sons for so well carrying out my design. T. FREDERICK PEARSE, M.D.

AT the annual meeting of the supporters of the Paddington-green Children's Hospital on the 11th inst., it was stated that the work of the institution continues to expand, and it is proposed by means of new buildings to increase the accommodation.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

WEDNESDAY, JUNE 9TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

THE PRESIDENT stated that he could now inform the Council that it was the intention of the Government to endeavour to pass the Medical Bill before the session closed, if they could get any Bill at all through.

The Council again resolved itself into committee to consider the reports by the Visitors of the final examinations.

Dr. MCVAIL, referring to the criticisms passed on the Glasgow examinations with regard to students acting as clinical clerks and obstetricians, said if the students were properly distributed throughout the hospitals of Glasgow, there would be ample material for everyone. Each teacher would have only twenty-eight students, and each student would have throughout his course the entire charge of two beds. That would be the result if the teachers were not also examiners. The result of the present state of things was that the larger of the two hospitals in Glasgow (the Royal Infirmary) had not at present a single university student attending it. The average number of such students attending was about one per annum, the highest number having been four. In the Western Infirmary some of the non-professorial teachers had extremely small classes, while the professorial classes were crowded. The question was one of great importance in Scotland, and it could not be settled so long as the examination was limited to teachers. It was true that there were assessors, but only in the proportion of nine to eleven. Until the present system was changed the great clinical field of Glasgow would not be utilised.

Dr. PETTIGREW said that in Edinburgh many of the extra-mural lecturers were examiners.

Dr. MCVAIL said there was not a single case of an extra-mural lecturer being an examiner in Glasgow, except in the case of pathology.

Dr. PETTIGREW said there was no doubt a difficulty with regard to coadjutor examiners, but it might be got over by their being appointed by the Council or some other competent body.

Dr. CHAMBERS said that, according to the list he had made out, it was almost impossible for the University of Glasgow to elect as examiners those who had not been teachers there. Of the graduates only thirty-three had attained eminence in their profession, and of these twenty-four were teachers. If, therefore, the examiners were not to be teachers there, they must be men who had no connexion with Glasgow at all.

Dr. MCVAIL said he would not restrict the examiners to Glasgow men.

Sir DYCE DUCKWORTH quite agreed that there was a great loss of clinical material in Glasgow, but the difficulty arose from the fact that the Western Infirmary was closely adjacent to the University buildings, and the students had a very short distance to go from their theoretical to their clinical work. It was of very great importance to have men as examiners who were absolutely above suspicion, and if the mass of the profession of the three kingdoms were not satisfied with the way in which the examiners were appointed, it behoved the Council to consider whether some alteration might not be made in the method by which they were chosen.

Dr. STRUTHERS agreed that outside examiners should not be local men, and it might be well that they should be appointed by some independent body—say the Crown or the Medical Council. The Scotch universities would be happy to accept such outside examiners. England would certainly be better for a number of universities like the Scotch and the German in its large cities.

Dr. PETTIGREW felt strongly that the system of teaching would be degraded if the Scotch professors were not allowed to take part in the examination. The whole difficulty was about the appointment of the coadjutor examiners, and he had no doubt that the Scotch universities would soon concede that point.

Dr. HERON WATSON said that until the University Court was reformed nobody in Scotland would have the least confidence in its appointing extra-mural examiners. In the coming days of the democracy these antiquated institutions would be swept away altogether, and their funds applied in a more reasonable manner.

Dr. HUMPHRY considered that the deficiency in clinical examination in Edinburgh was due to the deficiency in the number of examiners. It was not quite creditable to that university that there should be only two examiners to conduct the whole of the long examination in each of the clinical subjects; but if it were proposed to exclude the professors from the Scotch university examinations, he hoped that those universities would fight, for he believed they would be right, and being right would win.

The next report considered was that on the University of Aberdeen.

Dr. STRUTHERS informed the Council that there were two periods of graduation at Aberdeen, but the Visitors only attended at the end of the summer term, when the rejected men come up again. That might explain perhaps, why the Visitors had not indulged in such enthusiastic terms as they otherwise might have used. There was one unjustifiable remark in the report. Fault was found with the partial passes, and the system was spoken of as "lax." That was a censure that he could not submit to. The Visitors ought to be censured, and not the university. Mr. Holden, who wrote that report, ought to have known that the Council had already sanctioned the system which permitted a rejected candidate to be examined again in the subject in which he had failed.

Dr. QUAIN called the attention of Dr. Struthers and the Council to the following statements of the Aberdeen Visitors: "While we thus note the insufficiency of the practical element in the curriculum, it appears to us an open question if the student be not altogether over-weighted by the number of the lectures which he has to attend, inasmuch as the winter courses are defined to include not less than a hundred lectures, and the summer not less than fifty." "Our opinion of this examination was in the direction of its being too superficial and the judgments too lenient. At the same time we gathered that many of the candidates, from the readiness and peculiarities of their answers, were evidently familiar with the teaching of the Professor of Surgery (laughter); and we felt sure that, while they were theoretically conversant with the history and general main features of diseased conditions, the majority of those whose examinations we witnessed were decidedly deficient in practical training." Mr. Holden also reported: "According to present regulations at final examinations, it is obvious that surgery in its wide sense plays no prominent part. Rather is it left in the background. Candidates are not required to do any operations on the dead body. They are not asked to show their knowledge of surgical anatomy. They are very inadequately tested on bandaging and surgical appliances. For these reasons I cannot avoid the conclusion that at the final examinations the candidates for the double degrees of the University of Aberdeen are not sufficiently required to prove their competency in surgery, and that some of them are admitted to the degree of Master in Surgery on rather too easy terms."

Dr. HERON WATSON said there was some inconsistency in the report of the Visitors with reference to the insufficiency of the surgical examination, as contrasted with the statement that the surgical examination was "carefully conducted, and the adjudication of the candidates' merits equitable."

Dr. STRUTHERS said that on the subject of the students being over-weighted with lectures, the Visitors only reported that it was "an open question," and even from that statement Dr. Kidd, one of the Visitors, had dissented. The reason for his dissent probably was that he had been educated in Scotland and knew the value of a good lecture system. The Visitors in their report had spoken on the whole very favourably of the examinations. There could be no doubt that the school was *par excellence* a hard-working one. The students were being constantly and carefully examined, and he (Dr. Struthers) knew his students as well as he knew his own boys.

Dr. PETTIGREW, referring to the visitation of St. Andrews, said that the Visitors had made certain statements which he thought were not in accordance with the facts. Perhaps the proper explanation was that the authorities there were too good to them, and as the report was not written at the time, they had drawn a little on their imagination. It was incorrect to say that the examiners were appointed annually by the Medical Faculty, for they were appointed by the University Court. Dr. Pettigrew also gave explanations from the remarks by the body visited on some other [illegible]

Digitized by Google

in the reports, and claimed that St. Andrews had a higher percentage of eminent men as medical graduates than any other university.

Dr. CHAMBERS said that St. Andrews, according to the Medical Register, produced 2·3 per cent. of distinguished men, while the mean number of the ten universities was 5·2. The percentage of Cambridge was 25·7, of Dublin nearly 11, of the London University 13·1, so that it could hardly be said that St. Andrews beat all the others.

Dr. DUNCAN said that the Universities of St. Andrews and London really produced no men at all, but merely graduated them. Other universities and bodies educated them.

Mr. MACNAMARA said that the returns furnished to the Medical Council by St. Andrews showed that in seven years sixty-eight candidates had passed and only two had been rejected. There was a plentiful supply of reagents and specimens at the examination, but, as a matter of fact, not one of them was used, while the microscope was only employed by one examiner. The difficulty in St. Andrews was that there was no hospital, but he thought the students might call at Edinburgh on their way down, and there be clinically examined.

The Council then adjourned.

THURSDAY, JUNE 10TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

The Council again resolved itself into committee for consideration of the reports by the Visitors of the final examinations.

Dr. HAUGHTON, referring to the University of Dublin, said that the statement of opinion on the part of the Visitors and the answers of the Examining Court must be received with discount on both sides. The object of the Visitors, as far as he could see, had been to bury Cæsar, and the object of the examiners to praise Cæsar, and he had no desire to do either the one or the other. He was the last person in the world who would wish to assist at the funeral of the college founded by the right royal lion-hearted Queen Elizabeth, and he certainly would not be guilty of the bad taste of simply being present to praise that college; but he should like to point out that a number of serious charges had been made against it by the Visitors, founded upon supposed facts which, like certain German metaphysicians, they must have evolved out of their inner consciousness. Those misconceptions, however, had been so fully answered in the reply of the examiners that he need not go into them. The University had accepted two of the recommendations of the Visitors—that the examination for degrees should be more extended than that for licences, and that the extern examiners ought to give more marks for the medical degree examination; but with regard to their silence upon all the other recommendations in the Visitors' report, it meant a fixed determination not to adopt them. (Laughter.) They could never accept the proposal to introduce clinical and operative surgery into a medical degree examination, any more than they would acquiesce in the introduction of clinical medicine into a surgery degree because their examinations in medicine, surgery, and obstetrics were conducted quite separately. The principle, that excellence in one important branch should not compensate for failure in another, was carried out in its entirety at the University with regard to medicine, surgery, and midwifery.

Dr. BANKS also criticised the report of the Visitors, remarking that if they had not fallen into the misconception referred to by Dr. Haughton they might have saved themselves the necessity of making the rather severe criticisms upon the examination which appeared in their report. They had stated that the examination undergone in the University of Dublin by a candidate for the degree of Bachelor of Medicine did not entitle him to registration. It had never been claimed that it did, but when the curriculum for that degree was formulated it was never intended that physicians should be general practitioners, but it was now the practice in Ireland to obtain a surgical as well as a medical qualification. Dr. Banks then pointed out what he considered a contradiction in the report, the Visitor in one place stating, "I may also unreservedly praise the *vivâ voce* examination in materia medica and therapeutics"; and in another speaking of the "incomplete character" of the examination in "practice of medicine and materia medica and therapeutics." The report also stated that the candidate in each case had been examined by his own teachers, but that was incorrect, for neither he nor his colleague (the Regius Professor of Surgery) was a teacher, and they knew nothing of the candidates until they came up for examination. Another mistake—and a grievous one—was the statement that there was only required a minimum of six attendances in cases of labour, which was too low; whereas the University was not satisfied with less than six months' practical acquaintance with midwifery on the part of its students; and, as a matter of fact, candidates for the Bachelor of Medicine degree had to prove that they had attended from twenty to thirty cases. There was also a complaint that some of the candidates were allowed to be present during the examination of their fellows, but the fact was that no man was present at the examination of another candidate in a subject upon which he also would be examined.

Dr. CHAMBERS said that the University of Dublin was evidently attractive to the more industrious and diligent students, for no less than 10·8 per 1000 of school teachers had taken degrees there.

Dr. BANKS, dealing with the report on the Royal University of Ireland, said that the Visitors expressed in strong terms their approbation not only of the curriculum, but also of the conduct of the examinations. Their words were: "All the above examinations appear to us to be well and conscientiously conducted, and the marks awarded, as far as the plans generally adopted allow, to be just." "It is obvious that in the clinical examinations great care is taken to prevent the candidates from knowing where the examinations were to be held, and therefore on what cases they were to be examined." It was true that they remarked upon the unpreparedness of the candidates, and that the examiners fully concurred in that was proved by the fact that 50 per cent. of the candidates, were rejected. With respect to putting back candidates, it had not been found by experience that there was any inconvenience. It was in clinical medicine or surgery that they were generally sent back. The absence of pathological preparations and drawings was referred to in the report, but the fact was that the University buildings were not yet completed. He considered that such a young university had good reason to be proud of the report, especially when the Visitors were men of such eminence as Dr. Bristowe, Mr. Holden, and Dr. Leishman.

Sir DYCE DUCKWORTH drew attention to the statement that for the most part the candidates were examined by only one examiner. The opinion of the Council was that there should always be at least two examiners. One peculiar point in connexion with the Royal University was that anatomy and physiology were taken at the final examination. To compel candidates to keep up a knowledge of those subjects so as to pass another examination on them must have a very distracting effect on men who had to take up practical subjects at the end of their curriculum.

Mr. MACNAMARA said that the question as to when the study of anatomy should end was formerly earnestly discussed by the Council, and he took a leading part in opposing the view that it should be at the close of the second year. In that he had the support of Sir James Paget, and the result was a recommendation by the Council. Under the provisions of the Anatomy Act, no man could pursue his anatomical studies elsewhere than in a school licensed for the purpose. In Ireland everything in medicine and surgery was regarded as having its basis in anatomy, and it was remembered that after obtaining his qualification the student had no facilities for studying anatomy, though he had for every other branch of the profession. In any part of the globe he might study medical chemistry and materia medica, but not anatomy, and therefore it was necessary that he should utilise every opportunity at his disposal in the years when he could work upon that subject. The result was that Irishmen were vain enough to think that Ireland produced anatomists that could favourably compare with any from Scotland.

Mr. SIMON said it was very important that men should not be allowed to forget their anatomy; and when they were examined in surgery, if they betrayed ignorance of anatomy they should be plucked. The view of the Council was that a student carried his anatomy into practice, and examination in surgery and medicine involved reference to it; but they objected to its being taken as a separate subject in the final examination.

Mr. MACNAMARA said the Visitors acknowledged that the students were efficient in anatomy, because they said they

Digitized by Google

had already passed a stringent examination in it at the second medical examination.

Mr. SIMON asked if it were not possible that they would come out fresh in anatomy at the cost of being flabby in physic. The Visitors spoke of the lamentable ignorance displayed in medicine and midwifery on the part of a large number of students. That showed that they had been distracted from the study of those subjects, and gave their time to cramming for the anatomical examination.

Dr. STRUTHERS also thought it an injudicious thing to require anatomy and physiology at the final, especially after the students had passed a stringent examination in those subjects previously.

Dr. HAUGHTON said that the first act of the Royal University was to raise the standard of the arts examination preliminary to the study of medicine far above the level of the recommendations of the Council. They did this in the face of great difficulties, for there were vested interests of a serious kind involved in keeping down the standard of arts, and encouraging a minimum.

Dr. LYONS, M.P., thought that the Royal University, as a young university, might well be congratulated on having so successfully passed the ordeal of visitation. The Senate would be very happy, indeed, to apply themselves, as far as they could, to remedy any deficiencies that had been pointed out. The University had already raised to twenty the number of cases of labour which the students must attend, and he hoped that the Council would be able to secure that as a minimum in all schools. They had also made a special rule that at least ten fever cases should be attended, and, considering the great importance of the subject, not only in private practice but in connexion with the public service of the State, it could not be said that the minimum was too high. Attendance was also enforced on a limited number of cases in lunatic asylums.

Dr. BANKS, replying to an observation by Sir Dyce Duckworth, said the rule of the University was that there should be two examiners in clinical subjects, although there might have been some laxity in that respect on the occasion of the visit. The authorities were quite prepared to say that there should be no anatomy at the final examination.

Mr. MARSHALL moved the adoption of the committee's report. He said the discussion on the whole question showed how prudent those were who wanted to postpone the real report to the next meeting, and to present only a provisional report on this occasion. Almost every speaker had desired more information, and he concluded that the committee would be called upon to make a further report. In regard to the future, he could promise that the committee would endeavour to eliminate from their report everything that could be called personal to institutions, and devote themselves to the sole point of their consideration—the sufficiency of a registrable qualification. On that point a great deal could be learned from the valuable discussions that had taken place.

Dr. HERON WATSON seconded the motion, which was agreed to.

The Council then resumed, and Mr. Marshall again moved the adoption of the report, but on the suggestion of Dr. Quain and Mr. Simon the motion was withdrawn, the final acceptance by the Council being deferred until the entire report is presented.

The PRESIDENT said that, looking back on the various discussions of an educational kind that had taken place in the Council, he felt quite convinced that none had ever occurred which was more likely to be truly fruitful for the work they had in hand than that which had just terminated. It was quite clear that masters would be brought to a practical point with regard to the real requisites for education and examination in such a manner as they had never been before. If the new Bill passed, there would be a certain number of new members who had never taken part in the deliberations of the Council, and those gentlemen would have the advantage or disadvantage, as the case might be, of plunging into the middle of this intricate work. He felt that, whether the Bill were or were not the best possible solution, nothing could be so bad as the continuance of the suspense, and he hoped that, whether or not he lived and was able to join in the deliberations of the Council, there would be no jar in their proceedings. There were, however, pitfalls in the Bill which might almost compel them again to discuss the constitution of the Council, and for that reason, among others, he was thankful to see that these educational questions had been brought to such a point that, thanks to Mr. Marshall and his committee, it would be possible to continue the careful discussion of the details without any interruption. The new members would be welcomed as an addition to the Council, and would, no doubt, assist in bringing to a conclusion the long and anxious deliberations in which they had been engaged. He again thanked the members for the extreme kindness with which they had accepted what he had been able to do, assisted by the chairman of the Business Committee. He had had occasion several times to say that it was the happiest work he now had in life, and he should be sorry when the day arrived (which could not be far distant) when he would have to leave it.

The session then terminated.

PRESENTATION OF THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND TO MR. MARSHALL.

On the adjournment of the Council for tea, the Rev. Dr. Haughton, Honorary Fellow of the College of Surgeons in Ireland, and Professor Rawdon Macnamara, the representative of the College on the Medical Council, on behalf of the College, presented to Mr. Marshall the Honorary Fellowship of the College of Surgeons in Ireland, a distinction recently conferred upon him by that body in recognition of his valuable contributions to surgical science. Prof. Macnamara in a few well-chosen sentences conveyed to Mr. Marshall the sense of his College for his important services, and regretted the cause of his absence (illness) upon the public occasion when a similar distinction was conferred on Sir James Paget, who had then attended in person to receive the honour. Mr. Marshall, in accepting the diploma, which was engrossed on vellum, the seal of the College being enclosed in a handsome silver box, richly chased, expressed his high sense of the honour conferred upon him, acknowledged the important manner in which the Irish College of Surgeons had from its foundation laboured to promote surgical progress, and frankly admitted that personally he himself had derived no small amount of information from the writings and labours of Irish surgeons.

THE JUBILEE BANQUET OF THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editor of THE LANCET.

SIR,—I shall be glad to be allowed again to remind your readers of the jubilee celebration of the British Medical Benevolent Fund, on Thursday, July 8th. Already so many prominent members of the profession have intimated their intention to be present, that the gathering will be one of the most important which has taken place for many years. It was, indeed, to be expected that a desire to do honour to Sir James Paget would be a powerful influence in bringing together a distinguished assemblage, and this anticipation is being fully realised. Among those who may be expected to attend are Sir William Jenner, K.C.B., President; Sir Dyce Duckworth, Treasurer and Representative in the Medical Council; Dr. Habershon, Senior Censor of the Royal College of Physicians; Mr. John Wood and Mr. Henry Power, Vice-Presidents of the College of Surgeons; Sir Henry Acland, K.C.B., President of the Medical Council; Dr. Edwards, President, Dr. Withers Moore, President-elect, Dr. Balthazar Foster, President of Council, of the British Medical Association; Mr. George Pollock, President of the Medico-Chirurgical Society; Sir Andrew Clark, Bart.; Sir Prescott Hewett, Bart.; Sir Joseph Lister, Bart.; Sir Edwin Saunders, Sir Ed. Sieveking, Dr. Clifford Allbutt, Dr. Chadwick, Dr. Costes (Bath), Mr. Crosby (Manchester), Dr. Hare, Dr. Holman (Reigate), Dr. Langdon Down, Dr. Ord, and Mr. Winter (Brighton).—I am, Sir, yours faithfully,

June, 1886. W. H. BROADBENT.

CAMBRIDGE MEDICAL GRADUATES' CLUB.—The annual dinner of the Cambridge Medical Graduates' Club will be held this year at Cambridge on Saturday, July 17th. The Master and Fellows of Caius College have promised the use of the college hall for the occasion. The chair will be taken by Sir George E. Paget, M.D., K.C.B., and a large gathering of graduates is expected, as this is the first time the Club has met in Cambridge since its formation.

THE LANCET.

LONDON: SATURDAY, JUNE 19, 1886.

THE attention of our readers is directed to the Special Supplement which is published with our present issue. To-day we make an effort in the cause of all the hospitals, and urge their claims upon the liberality of everyone in the vast population which collectively constitutes London. It will be seen at once that the graphic account entitled "Within the Hospital Walls" has been written by a layman for laymen and others who have no means of realising what the inner life of the hospitals really represents. The writer had, as a matter of fact, never been in a hospital until he was commissioned to do this special work. It is therefore satisfactory to know that his visit to most of the chief hospitals have led him, as an experienced journalist, to form a conscientious conviction as to the reason for the present lack of funds. He declares that ignorance of the work is the cause of the indifference in the public mind which has led to diminished hospital supplies and impaired usefulness. We have often felt that there was a missing link in the whole of our hospital system which ought to be found and restored without delay. Whether a hospital is State-aided, rate-supported, endowed, or voluntary, the more the objects for which it is founded, the system upon which it is managed, the kind of accommodation it provides, the advantages it offers to its inmates, and the whole of its interior economy and working, are made familiar to the people, and the more the public are induced to inquire, examine, and understand every one of these points, the better it must be for all concerned. It would be a matter for congratulation if the managers of the various groups of hospitals, as well as those of individual charities, would make a practice of throwing open these establishments during a few days in each year, taking care at the same time to induce representatives of every class of their supporters and the public, as well as the wealthy, to visit them at such times. A reference to the Special Supplement of to-day's date will show how many hospitals are labouring under financial difficulties, and we cannot but hope and believe that the more intelligent of the managers will issue invitations during the next few days on the lines we have indicated, as well as to the speakers at the meetings and to the clergy, in anticipation of Hospital Sunday, June 27th. On a liberal estimate, not more than forty thousand persons give anything appreciable to the metropolitan hospitals, and it is stated by those who can speak with authority that at the outside only one Londoner out of every hundred contributes even a penny a year to the hospitals' exchequer. This fact is not more the fault of the non-givers than of the hospital managers, whose business it should be to press home upon the public conscience their claims to substantial recognition, and the imperative necessity for the efficient maintenance of the hospitals for the better preservation of the life and health of every individual inhabitant. It is of no use in these days sitting at home with folded hands, self-confident in the pressing claims of one particular charity; men must work now as ever for the triumph of their principles and the enforcement of the claims of the charities for the support of which they are responsible. In these circumstances all who can rightly appeal for support should throw open their hospital and invite the public during the next few days to enter and convince themselves that a liberal gift on Hospital Sunday is not only called for by charity, but that it is likewise a matter of self-interest.

We have said that the Special Supplement has been written for laymen chiefly and in pursuance of a plan we commenced last year, in the hope that a sum more worthy of the vast wealth of London may be raised annually on Hospital Sunday. The Supplement is necessarily popular rather than professional, and our readers may therefore like to hear an additional reason why we have been led to take this new departure. It is self-evident that the medical profession must have hospitals, just as the hospitals must be dependent upon the medical profession. Anything which tends to injure the one must prove inimical to the best interests of the other. Now the financial condition of more than one of the London hospitals to-day has created a feeling of alarm, and threatens the efficiency, if it does not indeed imperil the existence, of at least one of the medical schools. In such circumstances THE LANCET, as the representative of the medical profession, cannot remain a passive spectator of these threatened disasters, and so it has determined to co-operate in the most strenuous efforts to dispel the impending evils, and to secure the adequate support of all the hospitals. The six meetings which will be held during the Hospitals Week will commence on Monday, June 21st, at Lambeth Palace Library, where Sir ANDREW CLARK will urge the claims of the hospitals upon the people. The meeting will be addressed also by Lord SANDHURST, Under Secretary for War. On Tuesday the Earl of DARTMOUTH and Barons ROTHSCHILD and DE WORMS will address a large meeting at Blackheath. On Wednesday the Marquis of HARTINGTON, the Right Hon. W. H. SMITH, M.P., and Sir ALGERNON BORTHWICK, M.P., with Sir WM. MAC CORMAC, will speak at Kensington Town Hall. On Thursday Lord NORTHBROOK and Lord CHARLES BERESFORD, V.C., M.P., will address an audience at St. Andrew's Hall, Newman-street. On Friday the Duke of WESTMINSTER, Dr. BUCHANAN, Sir DYCE DUCKWORTH, with several metropolitan members of Parliament, will attend a meeting at the Highbury Athenæum; and on Saturday afternoon the 26th inst., H.R.H. the Duke of CAMBRIDGE and the Marquis of SALISBURY will address the working-men and others at the Stratford Town Hall. Nothing is wanted to make these meetings a success except that full report of the speeches of these eminent men which the editors of the daily metropolitan press will doubtless gladly give as their contribution to this united effort to arouse London to the needs of all the hospitals. In such a case the results achieved are well calculated to prove memorable, and a deep debt of gratitude will be due to the members of Parliament who have recognised the pressing claims of this great social question by turning aside from the pressure of politics for a brief space, in order to pay their donation to the hospitals in meal, notwithstanding the fact that most of them have not once, but often, paid already in malt—

Digitized by Google

i.e., by subscriptions to the hospitals' exchequer. We hope the people as well as the profession will attend the several meetings in great numbers, and that this year the interest aroused will cause the churches to be crowded and the collecting-bags to be filled to repletion at every service on Hospital Sunday, June 27th.

The cause represented by the work of all the hospitals and medical charities of London is one of the grandest that any speaker or preacher has ever had to plead. More than one million patients have been relieved in the course of a single year (1885), at a cost of something like half a million pounds sterling, or ten shillings per head. Of the ten shillings per head, about six have been supplied by the voluntary offerings of the people, three shillings represent the income derived mainly from the sums received from deceased benefactors, and the shilling per head per patient represents the actual deficiency which has to be made good if such a disaster as the closing of one or two of the largest hospitals is to be obviated. It comes to this, therefore, that one million—that is to say, more than one in four of the inhabitants of London—annually receive relief at the hospitals and medical charities. To meet the cost of this relief, one in every four Londoners is required to give one shilling a year to the Hospital Sunday Fund. If they do this, providing the forty thousand who at present charge themselves with the entire burden of contributing at least six of every ten shillings a year subscribed to the hospitals give as much on the 27th inst. as they gave in former years, then adequate funds will at length be subscribed to maintain the London hospitals in full working and efficiency. It is hard to believe that the three million Londoners who neither use nor support hospitals can always continue to be indifferent to this important matter.

This year a greater responsibility than ever rests upon the clergy and ministers of all the churches to specially charge themselves with the duty of rousing their congregations and the wealthier residents in their parishes to a sense of the duty of giving liberally to the Hospital Sunday Fund. The Council of the Fund send to each minister a bundle of letters, which have only to be signed and addressed to each person who is fairly well-to-do with the view of securing in this way many gifts which will otherwise not be procured. Canon FLEMING and the Rev. Dr. FORREST have made their collections the largest in London by the use of these circulars; and we call upon the clergy and ministers to respond to the special efforts of the laity throughout the Hospitals Week by charging themselves with the duty of preparing a list of the members of their congregations whom they believe can spare a special gift, and of sending to every name on that list one of those "golden pheasant" letters, as Canon MILLER used to call them. We propose to address the clergy in our next issue, and have only alluded to this point to-day because it will take time to carry out what is here proposed, and the work must be done in the course of next week. We hope also that every minister and clergyman will announce the day, place, and hour of the public meeting to be held in the district in which his church is situated during the Hospitals Week at each of the services on Sunday next (20th inst.), and urge his congregation to attend. In this way the £80,000 will soon be raised. But the duty of helping the hospitals is imperative upon all. Press and people, peers, peasants, and politicians, believers and unbelievers, young and old, rich and poor—all sorts and conditions of men and women, in fact, can combine, and ought to combine, to give, and to give liberally, in proportion to their means; not only as a great pleasure and privilege, not merely from gratitude for blessings enjoyed and still possessed, not solely from love to GOD and man, but also in self-defence, and because none know how soon they individually may have reason to bless the hospitals for good service rendered to themselves or their friends in the hour of their greatest need.

THE Medical Council concluded its session on the 10th inst. Sir HENRY ACLAND, in his concluding remarks, seemed to anticipate the passing of the Medical Bill and the probability that the Medical Council would shortly receive an accession of direct representatives to its ranks, whom, he was pleased to say, would be welcomed by the Council. The same night the Bill passed through Committee in the House of Commons, and soon after was read a third time; and, as we write, bids fair to meet with very little opposition in the House of Lords.

By far the most important business transacted by the Council was the discussion of the reports of the Visitors of the Examinations of the Universities. These reports have raised questions which it is desirable should be discussed from time to time. The universities need to justify their standards. It would be an unreasonable thing for them to persist in granting higher titles than the corporations if they cannot show that their examinations are higher. In very few of the reports or of the answers of the particular universities to the criticisms of the Visitors is this distinction clearly recognised. In the letter of instructions to the Visitors of the Medical Council, the Council did not go beyond requiring its Visitors to testify as to the fitness of the university examinations as tests of competence, justifying men being placed on the Register. But we are glad to see that one university at least recognises that something more is expected of it. The examiners of the University of London boldly speak of their standard, both in medicine and surgery, as being an academic standard, higher than a merely professional one. This is the proper estimate of university tests. If they fall below it, if they are merely equal in severity or in extent to those of a corporation, they must expect to be treated with much less reverence than heretofore. It is an excellent thing to have English examiners reporting on the system of Scotch and Irish university examinations, and Scotch and Irish teachers exercising their ingenuity in criticising the system of examinations pursued in the English universities. We cannot pretend to give the details of these reports; but we may indicate the questions they raise and the general drift of the opinion of the reporters. Our readers will gather from the debates in the Medical Council how candid was the international expression of opinion on the different methods of education and examination. The report on the London University is somewhat severe, considering the great importance of its examinations and the extent to which they have affected the standard of similar institutions. The criticisms on other English uni-

Digitized by Google

versities do not require much notice. The Visitors to Oxford cannot regard the examination for the M.B. of Oxford as an examination altogether of a higher grade; the tests are not more exhaustive or of a higher standard than are to be found elsewhere. In the case of Cambridge, though complaint is properly made that the candidates for the M.B. are not examined in clinical surgery, yet the examinations as a whole are pronounced to be high class. These for the Durham degrees, both for young candidates and those of some professional standing, passed with some credit, though the Visitors go out of their way to express their views on the gift of degrees to practitioners of standing. The Scotch professors were put upon their defence for inflicting long courses of lectures; for not requiring evidence of experience as clinical clerks and dressers; for not, excepting Glasgow, demanding operations on the dead body; for not requiring in practical midwifery more than attendance on six cases; for defective attention to clinical and operative tests of practical surgery in their examinations. It must be admitted that the examiners hit the weak part of the Scottish university system here—the disproportion between their clinical material and the great number of students whom they have to supply and teach. In Glasgow there is indeed no excuse for this, as was shown the other day by a deputation to Lord DALHOUSIE and the Lord Advocate, urging that the Royal Infirmary of Glasgow, with its splendid clinical field, should be organised into a college of the University. A larger number of patients are treated in this hospital than in any other in the country, and we cannot understand the policy of not making it available for university purposes. In Edinburgh and Aberdeen the difficulty of meeting the demand for large clinical material is much greater; but it must be faced. The regulations as to attendance on six cases of midwifery are ridiculous, the more so as, as Dr. BARNES points out in one of his reports as a Visitor, they have not necessarily been watched throughout or under the guidance of a skilled teacher. How can six cases fit a student for the common accidents of midwifery? Barring the points we have alluded to, the Scotch universities have no reason to be dissatisfied with the reports. Dr. BRISTOWE'S testimony to the quality of the medical examinations in Edinburgh and Glasgow is highly flattering, and enough to stimulate these great centres of medical light to eliminate every fault and supply every defect. His words, too, on another knotty point of the Scotch system of examination ought to be recorded: "I may add that I was especially struck at both universities (Edinburgh and Glasgow) with the general pre-eminence as oral and clinical examiners of those men who had long experience of teaching and examining, and were still teachers, in patience, in tact, and in power of eliciting from candidates the knowledge that is in them." The Irish universities did not come through the ordeal so satisfactorily. The reports of the visit to Dublin University especially disappoint us. Stress has always been laid by this university on its requirement from its graduates of a preliminary degree in Arts. The professional examinations for the Degrees in Medicine are merely those for the licence; and, strange to relate, the display of bad Latin in this university, which boasts of its Arts qualification, was exceptional. As Dr. GEORGE W. BALFOUR says, "For a B.A. to write 'Uncias sextos,' 'Drachmas quattuor,' 'Tussu urgente,' 'Aquæ laurocaceæ,' and 'Syrupi ammoniatis aromatus grana tirginta,' and other similar absurdities, is surely intolerable." And we must add that even Professor HAUGHTON was not effective in his defence, though supported, too, by Dr. BANKS. The report of the Visitors in the case of the Royal University of Ireland is also unsatisfactory. The Visitors remark with earnestness on the lamentably insufficient knowledge of practical subjects and the imperfect clinical training displayed by a large proportion of the candidates. The conscientious strictness of the examiners is emphasised and the proportion of rejections was large. The surgical Visitor thought the average quality of the candidates exceedingly low.

OF the valuable researches by M. BOUCHARD on the poisonousness of the urine we have already treated (*vide* THE LANCET, p. 750). This physiologist has continued his investigation, and has ascertained the influence of various conditions on the toxicity of the urine, thereby greatly enhancing the value of his former observations. The urine of healthy men varies in toxicity at different periods of the day and night, both in quality and degree. The variations are independent of the ingestion of food and the times of meals, and have no relation to the quantity of potassium eliminated. A new series of fresh experiments were made, which allowed the variations in the toxicity to be studied for different hours of the day in such a manner that they could not be ascribed to alimentation. The twenty-four hours was divided into three periods of eight hours each, one devoted to sleep; at the commencement of each period an identical quantity of food and drink of precisely similar material was taken by the individual experimented on. In ordinary life, the amount of toxic matter excreted by the urine in the three periods of sleep, morning waking and evening waking, is respectively represented by the numbers 3, 7, 5. When the above method of feeding was employed, the amounts in the three periods respectively were found to be 3, 7·5, 5·5, or practically the same as in ordinary living. The increase in the production and elimination of the poison begins at the time that sleep is commencing; the diminution in the discharge of poison commences in the middle of the waking period.

If feeding does not influence the variations in the urinary toxicity during sleep and awaking, it would be interesting to know what the results are during abstention from food. M. BOUCHARD, experimenting on the same individual, suppressed the meal given at the commencement of sleep, and then compared the total poisonousness of the urine secreted during the same period. He arrived at the seemingly paradoxical conclusion that leaving off food increases the toxicity by one-half; the amount being represented by 4·5 instead of 3 for the sleeping period. This increase in poisonousness cannot be ascribed to an augmentation of the mineral substances discharged, for these are, on the contrary, diminished. It appeared to M. BOUCHARD that it was rather to be explained by a superabundance of organic matters, incompletely oxidised, that characterises the urine of fasting—a fact that admits of an easy interpretation: man reduced to live at the expense of his own tissues, disintegration occurs with difficulty and incompletely; whilst in a normal

Digitized by Google

state of alimentation, descending metabolism occurs more readily and completely in the circulating nutritive material.

If the greater toxicity of urine secreted during fasting can be explained by a hindrance to complete oxidisation, the same interpretation should be applicable to the augmentation of the poison that happens during sleep, which is accompanied by a diminution in the consumption of oxygen. Conversely, we ought to be able to explain diminution of toxicity in waking hours by the increased activity of the waking state, in which more oxygen is consumed. This hypothesis was tested by experiment. In a man whose urinary toxicity had been several times estimated, both during sleep and waking, under his habitual sedentary mode of life in the city, M. BOUCHARD determined the alterations that followed the enjoyment of a day of great bodily activity in the open air of the country. From this kind of experiment it was discovered that muscular work in the open air suppressed 30 per cent. of the total urinary toxicity in the twenty-four hours. It suppressed 27 per cent. of that of waking, and 40 per cent. of that of sleep. The causes that influence the urinary toxicity may therefore act, not only during their application, but even for a long time after they have ceased to exist. No doubt this is the reason why the morning urine is more poisonous than that of sleep, and that of sleep less noxious than the evening urine. For during the night less oxygen is taken up, and so less destruction of toxic matters takes place, as sleep is continued; whereas at the commencement of sleep the influence of the day's oxygen has not worn off, and destruction of the poison proceeds comparatively quickly. It seemed to M. BOUCHARD that in the physiological conditions of normal alimentation, fasting, sleeping, resting, waking, and working, the variations in toxicity depend especially on the greater or less degree of oxidation. This view was confirmed by another experiment in which the organism had a large quantity of oxygen placed artificially at its disposal. A healthy man, whose toxic data had been ascertained over several days for periods of four hours, and whose food was uniformly repeated six times a day at regular intervals so as to eliminate any influence thereby exercised, was placed in an atmosphere of compressed air at a pressure of 116 centimetres for four hours; the toxicity of the urine was diminished by 43 per cent. Further, for the twelve hours following the toxicity still remained below normal, and was, in fact, 66 per cent. less than that of the corresponding period of the preceding day. After the twelve hours the poisonousness augmented, and in the eight hours ensuing it surpassed by 33 per cent. the normal of the preceding day.

IN a recent article on the Contagious Diseases (Animals) Bill we expressed the hope that all the necessary powers are being conferred upon the Local Government Board for the prevention of milk infection which can now be perceived to be necessary, and which may be more fully required as additional knowledge is gained. The powers we indicated were those which would enable the Central Board to prescribe regulations dealing not only with contamination of milk by infection communicated through contact with a human being suffering from specific disease or some fault in what is usually understood as the sanitary condition of the farm, but also conditions relating to the cow herself as a possible cause of infection of milk either before or at the moment of the milk leaving her body.

An analysis of all the circumstances of a number of milk epidemics has frequently failed to show that disease has been caused in any of the usually accepted ways; and although no special condition of the cow has been associated with its production, a strong suspicion has been created that some unrecognised ailment of this animal might be responsible for the occurrence. This suspicion is now amply confirmed by Mr. POWER'S investigation into the recent outbreaks of scarlet fever in North and West London, and we are led to examine more critically the Bill which has now passed its third reading in the House of Lords and its second reading in the House of Commons, and for which there is much probability that it may, as an unopposed measure, become the only law upon which we shall have to rely for the prevention of the serious loss of life which from time to time results from the distribution of infected milk.

We are now informed, on competent legal authority, that the transference to the Local Government Board of the powers vested in the Privy Council of making general or special orders under Section 34 of the Contagious Diseases (Animals) Act of 1878, for prescribing precautions to be taken for protecting milk against infection or contamination, does not enable the Central Board to prescribe other regulations than those which relate to infection of milk after it has left the animal. Under these circumstances, we are compelled to regard the Bill now before Parliament as wanting in the very provisions which recent additions to medical knowledge have shown to be essentially necessary, if the Bill is to serve the purpose for which we presume it is being enacted.

Mr. POWER'S report has indeed seriously raised the question whether the prevention of milk infection would not, in the interest of the milk-consumer, be far better in the hands of the Privy Council, which possesses a veterinary department having some of the most trusted members of that profession for its guidance, than in those of the Local Government Board, which is altogether without such aid. If this course were adopted, it would certainly be necessary to amend the section to which we have referred, in such a manner as to confer upon the Privy Council the increased powers which we are convinced are required; but if it should be held that the whole duty of guarding the milk-consumer against the risks to which he is liable can be better administered by a Board having for its object the preservation of the public health, it becomes an absolute necessity that that Board shall not be wanting in the opportunity of fulfilling to the extent required the serious duties which would devolve upon it. It would, indeed, be lamentable if the Local Government Board should be unable, through faulty legislation, to take the very steps which a recent report of one of its officers has shown to be essential to the safeguarding of the public health.

A WORK on the Use of Photography in Illustrating Bacteria, by Dr. E. M. Crookshank, is in course of preparation for publication by Mr. H. K. Lewis. It will be illustrated by fifty permanent plates produced in special colours by the Autotype Company from the author's negatives.

Annotations.

"Ne quid nimis."

THE "INSANITY" OF KING LOUIS OF BAVARIA.

A MORE regrettable ending to what was either an ill-reported or a very obscure case than the suicide of King Louis of Bavaria it would be difficult to instance. What precisely the commissioners mean by "paranoia," as used in their report, we cannot pretend to determine. Vaguely, of course, παράνοια may be applied to any state of mind in which νοῦς is wanting or defective; but when it was said of the late King, as reported, that he was "suffering from that kind of mental disease which is well known from experience to medical men, and which is called paranoia," a suggestion of particular diagnosis was given for which the term employed offers no sufficient justification, at least none that we can recognise. And when it was further explained that "in view of the kind of disease, and its gradual and continual development, which has been going on for years, his Majesty must be deemed to be incurable, and a further loss of mental power may be expected with certainty," a prognosis was made to depend on premisses which were either inadequate or were simply not stated. We must confess ourselves inclined to agree with the personal physician of his late Majesty rather than with his more recent medical attendants, and to believe that Louis II. of Bavaria was eccentric instead of being actually insane, notwithstanding the presumptive evidence of his neurotic inheritance and bad family history; and it seems highly probable that, whereas during his ill-ordered life his eccentricities were rather encouraged than discouraged by the mismanagement of those around him, his suicide was the result of a determined and conscious purpose to put an end to a life which was cruelly blighted, instead of being an act of pure insanity, as now represented. If the King had been insane, with suicidal tendencies, measures would certainly have been taken to secure his safety. It is inconceivable that immediately after the creation of a sense of grievance so great as that to which his late Majesty gave expression—however needful it may have been to take the step which gave rise to the feeling—physicians experienced in the treatment of the insane would have permitted him to be alone with only one person. Of all persons, Dr. Gudden was the very last with whom the king should have been left in solitude. There was not wanting a clear intimation that his Majesty regarded the declaration of his insanity as a wrong which he could not outlive. In short, it was known that the King contemplated suicide. The precise truth about King Louis's vagaries will never, probably, be known. His public proceedings do not accord in spirit with the private acts attributed to him. That he was surrounded by a class of persons not able to understand his peculiarities is beyond question. We can only hope that the personal physician of his late Majesty, who knew him better than anyone else, will furnish, at least for the medical profession at large, a full report of the case, and that this will be considered together with the statement of the experts, and with the report also of the post-mortem appearances. As the case now stands, we cannot but think it is chiefly notable for the extreme mystery which enshrouds it.

CONTAGION OR INFECTION?

THE imperfection of language is responsible for no slight amount of confusion and indefiniteness in the nomenclature of morbid processes. Perhaps the most striking instance of such difficulties is to be found in the use of the terms "infection," "infective," "contagion," and "contagious." According to the idea most prominent in the mind of a person who employs one or other of these phrases is the significance which he attaches to it. Thus we often hear of such a malady being contagious, but not infectious; of a morbid process being infective quite apart from any notion of contagiousness. Perhaps the most common kind of distinction is that which would limit the term "contagion" to such disorders as are only communicable by direct contact, and would employ "infectious" to denote those which are communicable through such media as the air, water, or soil. The distinctions thus created are, however, wholly artificial; for if we separate from the two groups such affections as cholera and typhoid, by following Pettenkofer in placing them apart as miasmatic-contagious disorders, we shall practically find that the limits between mere contagion and infection are reduced to a vanishing point. For practically even the most locally contagious disorders may be communicated indirectly, but of course far less frequently or certainly than the highly infectious diseases are. The word "contagion," then, covers them all, and the question becomes one simply of degree. The term 'infective" is, however, receiving a wider significance by being used in another direction—as, for instance, in its application to such diseases as septicæmia and pyæmia, to which the word "contagious" is inappropriate. When, however as, recently occurred—the occasion giving rise to some rather cynical remarks in a lay contemporary,—the notion is expressed, or rather implied, that diphtheria is not an infectious disease, we are brought face to face with the practical inconvenience of the term. Compared with scarlet fever, the virus of diphtheria is no doubt far less easily disseminated, and, in the majority of instances, it is communicable only by direct contact. But all authorities are forced to admit that the diphtheritic poison can be conveyed aerially or by fomites, and that therefore it is an infectious as well as a contagious disease. The College of Physicians has done much to place the nomenclature of diseases upon a scientific basis; it might go further and seek to define the proper use of terms such as those to which we have alluded.

LORD WOLSELEY ON LARGE HEADS AND NARROW CHESTS.

"How often had they seen a young stripling leave a school—at least, he himself had seen it—and join the army, one who ought to have had spectacles, for he could barely see, with a large head and very narrow chest. That was not the sort of young man they wanted in the army." So spoke Lord Wolseley at the Oxford Military College, a public school founded in 1876 in rivalry with Wellington College, for the education of sons of officers in the army. In addressing himself to the students, Lord Wolseley further remarked that "he was quite certain that when they left the college, they would leave it with an enormous number of chances in their favour over those young men who would leave many of the great schools, where the physical training of youth was not so equally or so sufficiently attended to." Of young officers under the strain of actual warfare, Lord Wolseley's experience is probably the largest of any living officer of high repute, and for degrees of physical fitness to be so apparent, as his speech at the Oxford Military College appears to imply, is a grave matter. We have long had serious doubt as to the fitness of the physical and intellectual training at some of our public schools. There should be no preponderance of one over the other, but a judicious balance

Digitized by Google

of the two essentials for an active intellectual life, blended with the strain on the physical such as most occupations necessitate. To a successful military career in these days, physical fitness, as well as high intellectual attainments, are essential. It would be interesting and instructive to have statistics of the number of young officers who have succumbed to disease while on active military service, and the public schools at which they were educated. We hope Lord Wolseley will direct attention to this subject, and that military surgeons may be required to make note of the relative mortality from disease among officers from the different public schools.

FORESTS AND ROMAN MALARIA.

THIS subject has been treated with characteristic clearness and power by Professor Corrado Tommasi-Crudeli in the *Nuova Antologia* of last February. Without attempting a literal translation of the memoir, it is yet possible to convey its teaching. The idea prevails very generally that malaria is produced by forests, independently of the nature of the soil which they cover. Many forests may be met with in which the production of malaria is very abundant; and vast tracts of land exist which were uninhabitable for malaria so long as they remained wooded, and which, when cleared, became more or less completely healthy. These facts are attributed by some to the putrefaction of dead leaves and insects slowly decomposing on the soil. But this explanation is inconsistent with the fact that many forests are free from malaria, although an enormous mass of animal and vegetable detritus accumulates and putrefies on the soil. By parity of reasoning another explanation of the same facts breaks down. It has been said that forests generate malaria because persons entering them from sunny parts catch cold. But there are woods which are very cool in summer, in which no one ever contracts fever; whereas some forests in the plain, without any ventilation, in which the temperature is often higher than in the surrounding country, are nevertheless eminently malarious. Forests are only factors of malaria in an indirect manner; they do not themselves produce it, but they favour its development, *when they cover malarious soil.* They intercept the solar rays, and thus check evaporation and retain moisture in summer, even in the strata which are in direct contact with the atmosphere. If these superficial strata do not contain the malarious ferment, the wood is innocuous; but if they contain it, the forest favours the production of malaria by maintaining moisture. When from land so infected is removed the obstacle to the direct action of the solar rays, the summer drying lessens the malarious generation, and in some favourable circumstances may even arrest it. While this experience has been very generally recognised and acted upon, the idea prevails in Rome that in malarious districts woods should not only be retained but extended. Ill-informed persons speak of sirocco (due south) winds which carry malaria from African marshes; and hence the necessity of opposing to these winds a barrier of littoral forests, which may arrest in their foliage the maleficent effluvia of exotic origin. They do not reflect that if Roman malaria had such an origin, Marsala, which is the Italian city most directly exposed to the current of the true African sirocco, should be plagued, instead of being healthy, as it is. Others speak of malaria produced by the marshes of the Roman littoral being carried into Rome by the sirocco winds, and hence they advocate, between Rome and the littoral marshes, the filtering woods. This doctrine was first advanced by Lancisi, physician to Pope Clement XI. in 1714. He believed in the transmission of malaria from the Pontine marshes to Rome, and in its arrest by the filtering action of the forest foliage. But at [illegible] it has been proved that the destruction of [illegible] forests has not led to an increase of malaria, but frequently to its mitigation in consequence of better drainage and improved cultivation. The production of fevers in the Agro Romano and in Rome is the result of a complexity of meteorological and physiological conditions. An abundant development of malaria is verified only when the malarious soil (*terreno malarico*) is damp and warm. The malarious charge of the atmosphere may vary greatly, according to the different proportion of the two indispensable factors of malaria—heat and moisture. If both are at their maximum, so is malaria, especially when the sky is clear. When the malarious charge of the atmosphere has been great for many days in succession, and the bodies of the inhabitants have become more or less impregnated with the malarious germs, a fall of temperature may be very injurious, by causing an arrest of the germs within the organism and preventing their rapid elimination by the secretions. Hence it is that northern winds often exercise an unfavourable influence during the fever seasons. On the other hand, it often happens that southern winds, and even the warmest of them—the true sirocco,—blow without doing any harm, because they are not of themselves carriers of malaria, or at any rate they convey it so diffused as not to determine infection in human organisms; while they cannot produce it by raising, as they do, the temperature of the Agro and of Rome when they find the malarious soil of the district dry.

DEATH AFTER VACCINATION.

AN inquest was held on June 11th on the body of a twin child which had died six days after vaccination by the public vaccinator. A medical witness is reported to have deposed that he was called to see the deceased, who had been dead for upwards of an hour, that he had made an external examination of the body, and found three distinct scratches on the left arm, with a little swelling; the deceased's countenance was very pale, and her fingers and thumbs were drawn together towards the palm of the hand. Witness, it is said, attributed the death to blood-poisoning arising on vaccination, brought on by an unwholesome vaccine matter being inserted in the deceased's arm, and the jury returned a verdict of "Death from blood-poisoning arising on vaccination." In the interests of justice, it is much to be hoped that further inquiry will be made into the cause of death. It is not easy to understand how an external examination of the body should have sufficed for the opinion which is reported. The other twin was vaccinated at the same time and remained in good health, and inasmuch as the operation was performed at a public station, it may be anticipated that more children were inoculated with the same lymph. The statement that unwholesome vaccine matter had been used clearly demands inquiry.

LECTURES TO MEDICAL PRACTITIONERS IN GLASGOW.

A PROPOSED course of lectures to practitioners is, we believe, being arranged for in Glasgow. The proposal is to have practical lectures on certain branches to which the lecturers have paid special attention, and to make them illustrative as much as possible. Dr. Gairdner is expected to lecture on the Abdominal Diseases associated with the name Tabes mesenterica in the Registrar-General's returns; Dr. Joseph Coats on the Pathology of Phthisis Pulmonalis, especially in regard to its causes and associated lesions in other organs; and Dr. Newman on Affections of the Kidneys to which surgical treatment is applicable. The course will extend over the first three weeks in October, there being two meetings weekly, at each of which two lectures will be given. Each lecturer will therefore give four lectures, and the entire course will include twelve lectures.

EFFECTS OF VARIOUS DRUGS ON PEPTONISATION.

DR. KLIKOVICH has examined the effect of various drugs on artificial digestion, publishing an account of his observations in the Russian *Weekly Clinical Gazette*. His method was to determine the quantity of peptone after the action of artificial gastric juice for from four to six hours on dry egg-albumen and inspissated blood-serum. This estimation was made by the polarisation instrument of Soleil and Wentzke and by an instrument of Lorant's. For the preparation of the artificial gastric fluid, from 0·5 to 1·0 gramme of pepsine was added to a litre of water containing 10 cubic centimetres of officinal hydrochloric acid. For each observation from 20 to 40 grammes of albumen and 450 grammes of the digestive fluid were employed, 50 cubic centimetres of a solution of the drug whose action was to be examined being added, and a control experiment without the addition of the drug being arranged at the same time. In this way the following results were obtained:—Alcohol, when less than 5 per cent. of the whole mixture, exercised no deterrent effect on the peptonisation, 10 per cent. decidedly retarded it, and a still larger proportion arrested the process entirely. Antipyrin, in quantities up to 2·5 grammes, had no effect; larger quantities had only a slight retarding action. Iodide and bromide of potassium, only when in considerable quantities, interfered with peptonisation; thus 0·5 gramme of the bromide had no effect, but 1 or 2 grammes showed a tendency to prevent it, the iodide acting rather more energetically in the same way. Organic salts of iron had no effect, but reduced iron and its inorganic salts exercised a decidedly adverse action on the process. Calomel, in quantities of from 0·3 to 1 gramme hindered peptonisation, but not to a very great degree. Arsenite of sodium, when in quantities of from 0·05 to 0·1 gramme, did not appear to affect the process in any adverse manner; but from 2·5 to 5 grammes of salicylate of sodium produced a marked retarding effect. The sulphates of sodium and magnesium, even in small quantities, hindered peptonisation. Chloral hydrate, in quantities below a gramme, had no decided effect; but when from 1 to 5 grammes were present a very marked effect was produced, and when more than 5 grammes were introduced the process was absolutely arrested. Chloride of sodium, in quantities of a gramme, had little or no influence. Acceleration of the process did not occur even with very small quantities, but with large ones a retarding effect was observed. Chloride of potassium gave similar results.

NIGHT-SCAVENGING.

WE have on numerous occasions referred to the grave objections which attach to the old-fashioned system of scavenging by night, which is in operation under a considerable number of somewhat antiquated bye-laws, and which the Local Government Board now invariably refuse to sanction. If the construction of privies and ashpits is such as to prevent decomposition of contents, and hence offensiveness during the process of scavenging, the sooner the matter is brought to the light of day the better. But to do the work under cover of darkness goes far to prevent the needed improvements, and any specially offensive methods of carrying out the removal cannot be properly supervised and checked. For these and many other reasons the system of night-scavenging should be abandoned; and if in the interests of the community it be thought well to restrict the period during which the process may be carried out, this can easily be done by arranging that it shall commence with the beginning of daylight and be discontinued early during the forenoon. Dr. Scott, in reporting on the sanitary condition of Ilkley, informs his readers that up to the begining of the year the emptying of ashpits and the removal of refuse were satisfactorily carried out, but at that date the contractor refused to comply with the request of the authority to do the work under cover of darkness, and hence the duty of scavenging fell into other hands. In a very short time it became evident that the change had become "disastrous," and the sanitary authority were compelled to undertake the work themselves. If the Ilkley Local Board of Health have conditions in connexion with this work which need to be kept from the eyes of their visitors, they had better amend the defects, and not try to get over the difficulty by ordering the scavenging to be done when neither the workman nor the officials who should supervise him can see what they are about.

"CAN IMAGINATION KILL?"

THIS is, perhaps, hardly the correct form of question that the *British and Colonial Druggist* puts to itself in discussing the death of the young woman at Hackney under circumstances in which Keating's insect powder largely figured. As the powder appears by Dr. Tidy's experiments to be perfectly harmless the suggestion is not unnaturally made that the deceased, who was possibly of a hysterical, highly imaginative turn of mind, took the powder in the full belief that by its means her death might be accomplished? The writer of the article in our contemporary, we think wrongly, brings forward two remarkable instances of what may be regarded as practical jokes with melancholy terminations. In the case of the convict delivered up to the scientist for the purpose of a psychological experiment (the man was strapped to a table and blindfolded, ostensibly to be bled to death; a syphon containing water was placed near his head, and the fluid was allowed to trickle audibly into a vessel below it, at the same time that a trifling scratch with a needle was inflicted on the culprit's neck; it is said that death occurred at the end of six minutes) fear must have played no inconsiderable share in the fatal result, and we do not know whether all the vital organs were in a sound condition, though they were presumably so. The old story of the case of a college porter is also one in point. The students entrapped him into a room at night, a mock inquiry was held, and the punishment of death by decapitation decreed for his want of consideration to the students. It is small wonder that, under the dominion of fear and belief in the earnestness of his tormenters, the sight of an axe and block, with subsequent blindfolding and necessary genuflexion, a smart wrap with a wet towel on the back of his neck should have been followed by the picking up of a corpse.

MOORE'S TREATMENT OF ANEURYSM.

AT the recent meeting of the American Medical Association Dr. J. Ransokoff related a case of aortic aneurysm, in which he had practised the introduction of wire into the sac. The patient was a coloured man, thirty-five years of age, and the symptoms which had lasted nearly ten months had dated from a sudden and severe effort. The aneursym sprang from the ascending aorta and formed a considerable prominence on the chest. Treatment by rest, restricted diet, iodide of potassium, and ergotine injections failed to produce any amelioration of the condition; and accordingly, in June of last year, Dr. Ransokoff introduced eight feet of silver wire into the aneurysm, passing it in through a tubular needle. When half this quantity had been passed in, the man became alarmingly faint, and was only revived by injections of whisky. For a fortnight the patient improved, the cough and dyspnœa were less, the œdema of the neck and face subsided, the tumour was firmer, and the pulsation not so marked. Then the prominence and pulsation of the inner part of the tumour increased, and the

Digitized by Google

operation was repeated, ninety-eight inches of wire being inserted this time. Again the tumour became firmer, but the symptoms were not relieved, and the man was found to be dead in his bed eight days after the second operation. At the necropsy the aneurysm was found to measure 7 in. by 4 in. In the upper and outer third of the sac a thick, firm, adherent, laminated clot was found, and the rest of the sac was lined with a thinner layer of clot. In the clots were found the coils of silver wire. The cause of death was rupture of the sac into the right pleura. The result of the treatment in this case was less successful than that obtained in Dr. Cayley's case, where life was prolonged for several weeks; but it shows that the operation is not beset with difficulty or grave danger, and that it is successful in exciting coagulation in an aneurysm. Dr. Ransokoff used silver wire. Small steel wire is better adapted for the purpose, being less liable to pass from the aneurysm into the artery. The liability to this was shown in Dr. Ransokoff's case, for at the necropsy a coil of wire was found lying just above and close to one of the aortic cusps. There are now some fifteen recorded cases in which Moore's treatment has been practised; more or less distinct improvement has been noticed in at least three cases, but at present we cannot refer to one of complete cure. Considering the desperate nature of the cases in which such a treatment is indicated, such a result is not discouraging.

"WORK AND WARM WEATHER."

UNDER this heading a contemporary asks, "Ought anything whatever to be done in hot weather?" As yet the season through which we are passing has not afforded any great need or occasion for the inquiry; but we agree that 'the subject is well worth considering." After it has been proved to demonstration that nothing whatever should be done, in schools particularly, during hot weather, we shall be quite prepared to making common cause with the school children in the endeavour to demonstrate that it is undesirable to do anything in cold weather either. In short, let us give up eating, drinking, working, playing, sleeping, and living in the last issue, lest some harm should befall. It is rank nonsense to write and speak as too many who ought to be better informed are writing and speaking just now, as though every act of existence were beset with peril. It would be better for all of us and the world at large if less ingenuity were expended on the invention of "scares," and in the pitiful task of working on the fears of the public. There is a broad line of truth and prudence between the avoidance of obvious follies in self-management and the care of the mind and body, and that crazy dread of disease which makes men and women for fear of death pass their whole lives in bondage.

AN EPIDEMIC OF ANCHYLOSTOMA IN HOLLAND.

SINCE the epidemic amongst the workers in the St. Gothard tunnel, attention has been directed to the occurrence of the comparatively rare parasite Anchylostomum duodenale amongst miners and brickmakers, and cases have been described by Meusche of Bonn, Leichtenstein of Cologne, Masius of Liege, and Mayer of Aix-la-Chapelle. Recently, too, Dr. Victor Dubois has communicated to an Amsterdam medical journal an account of a series of fourteen cases occurring amongst brickmakers in some villages near Maestricht. All the patients were extremely anæmic, and complained of pain in the epigastrium. At the commencement of the disease they all suffered more or less severely from diarrhœa; palpitation was complained of by all, and most of them were greatly debilitated. Three presented some œdema of the eyelids and anasarca of the lower extr[illegible] All had increased appetites, but no craving for special kinds of food. Vomiting occurred only once, and a slight rise of temperature once. The urine was always normal. The fæces usually presented a very dark brown appearance. The moist clay, with which the patients had to work, was found to contain in the middle of the summer the ova of anchylostoma. When fæces containing the ova were mixed with the clay and kept in a room at a temperature of 20° C. for four days, larvæ developed in the mass. The anchylostoma did not always exist alone, as in some cases oxyuris or trichocephalus were found in conjunction with them. With regard to treatment, iron was given for the anæmia in some cases, and appeared to cure it and to destroy the parasites as well. Santonine was given to some, and others were treated on Lutz's system with large doses of thymol, after a previous clearing out with calomel and senna, and this brought away large numbers of the entozoa, even in cases where the male fern had been previously administered.

MANIA CONCIONABUNDA.

Is it quite healthy, all this feverish struggle for prominence in affairs, this pushing and elbowing to the front, this passion for hearing one's own voice in public? Celsus describes epilepsy as a "morbus comitialis," so-called from its occasioning comitia to be prerogued if a case of the disease occurred during the proceedings; but had that sensible writer lived in the last quarter of the nineteenth century, he might have modified his classification so as to make the comitia themselves the malady and welcomed the epileptoid seizure as a more or less heroic remedy. M. Regnard, at a recent conference, drew the attention of the Scientific Association of France to a form of derangement which he calls "monomanie grandiose," a mania comparatively new, either because in ancient times it gave to those affected by it a peculiar aureole which imposed on their fellows, or because the conditions under which it is engendered are essentially modern, chief among them being the high-pressure education which inures young ambition to shrink from no task however impossible, and to attempt every aspiration however transcendental. Over and above the struggle for existence there is the struggle for success, in which the weaker, who are often the more ardent, are apt to prove the readier victims; for besides the causes that favour the "monomanie grandiose"—causes inherent in the moral atmosphere around us,—there are others peculiar to the individual; causes often, indeed, hereditary, which the alienist statistician finds more pronounced among the male sex than the female, among bachelors than among the married. Of this mania there is one form in which its subject flatters himself that the world is conspiring against him, lying in wait to circumvent him and achieve his destruction. There is another—and victims to this form are rather in force at present,—in which the subject is persuaded that mankind are dying for want of him panting to put themselves under his guidance, and anxious, above all things, to hear him speak. M. Regnard cites the case of a young ecclesiastic who, having gone through every stage of "monomanie grandiose," ended by becoming completely mad and calling himself the "complementary supplement to Pope Leo XIII." M. Regnard might easily have swelled the list with specimens drawn not from divinity, but from politics. "Complementary supplements" to Mr. Gladstone or Lord Salisbury (for "monomanie grandiose" has no party distinctions), who have convinced themselves they are "patres patriæ," saviours of society, whose departure-point is the public platform, and whose hoped-for terminus is the House of Parliament. Science gives to their disease the specific name of "mania concionabunda," a mania, that is, which addicts itself to popular meetings and harangues, to placarded manifestoes and controversial encounters before

Digitized by Google

the multitude. True, the terminus is not always reached; there is a burst-up or a collision, and the victim is lost sight of, only, however, to be replaced by others not less eager. M. Regnard, having defined the malady, its symptoms, and its course, next applies himself rather despondingly to its cure. Copious "bleedings"—in the pecuniary sense—have been partially successful, but removal from the moral contagium is his wisest suggestion. This, accompanied with a steady course of inductive science, beginning with its originators, "Novum Organum," and pausing over Aphorism 77, where we are admonished that "when the populace applauds us we should ask ourselves what fault we have committed," may with some confidence in the result be put in practice. For humbler cases, M. Regnard is reminded of the two Quaker brothers whose joint vocation was commerce. One of them, afflicted with "mania concionabunda," was unsuccessful in his political venture, and thereupon received the fraternal prescription: "I have heard of thy defeat, William, nor do I greatly grieve at it; for now thou wilt drop other people's business, and attend to thine own."

CHOLERA INTELLIGENCE.

THE cholera news which has reached this country during the past week has been somewhat disconnected. It is, however, evident that the disease still prevails in several portions of Italy. Thus, in Venice, an increase in the daily number of attacks has taken place, and, according to a correspondent of the public press, as many as thirty-nine fresh cases have been notified in one day. Other returns are to the effect that during the week ending mid-day of the 14th instant the daily attacks have varied between five and twenty-one, and that the total cholera deaths for the week have been fifty-seven. Venice is, in fact, deserted by all visitors and pleasure-seekers, and the authorities are endeavouring, by placing military guards over the houses affected, to keep the disease from extending further. These measures, however, appear to be comparatively useless. Some attacks have taken place in Florence, but they seem to be the result of importation from Venice, and this notwithstanding the attempts that are made strictly to isolate the households attacked. Bari and Brindisi also continue infected. As regards Bari, eleven deaths have taken place during the week ending the 14th inst.; but as to Brindisi, no records of cholera deaths find their way out of the country. Oria, an inland town in railway communication with Brindisi, has also been affected. The latest news of the extension of cholera comes from Trieste, where, on June 12th and 13th, two fatal attacks occurred in different parts of the town. The disease is therefore prevalent in various parts of the kingdom, and its maintained persistence in one or two places at the two extremes of the peninsula must still be regarded as giving ample grounds for anxiety as to the future.

SMOKING TOBACCO.

THE use of tobacco, as distinguished from its abuse, ought to be a matter of intelligent observation and experience. We should incline to the opinion that any particular individual who can say, "I always know when I have smoked enough—if I go beyond the just limit I lose my power of prompt decision," had better not smoke at all. It is clearly unwise for a man who cannot swim to persist in dabbling in deep waters. There are currents and under-draughts which may at any moment destroy his balance. The very reverse of the complaint made by this person is the experience of most smokers. A moderate use of tobacco soothes the senses, and leaves the mental faculties free from irritation and ready for calmly clear intellectual processes. When this is not the effect produced by smoking, the "weed" had better be eschewed.

THE SIGNIFICANCE OF COLLAPSED BOWEL IN OPERATIONS FOR INTESTINAL OBSTRUCTION.

IT is generally held that in intestinal obstruction the bowel above the obstruction is dilated, and that below it is collapsed. And of this fact practical use has been made, for in case of doubt as to the seat of obstruction when operating for its relief, collapsed bowel has been sought for and followed up to the lesion. Dr. Michael, of Baltimore, has published a short note in the *Medical News* of May 29th, to show that this rule is not without exceptions. He mentions two cases which occurred in his practice this year. In the first case, on opening the abdomen he at once saw collapsed small intestine; but he subsequently found the transverse colon so distended that the peritoneal coat was ruptured in several places, and the seat of obstruction was a stricture of the sigmoid flexure. In the second case, also, coils of collapsed small intestine were at first seen, and then the cæcum and sigmoid flexure were found distended above a stricture in the latter portion of the bowel. The "note" is very short, and no explanation of the fact is given. Such cases are notable exceptions to the general rule, and as such they are well worthy of regard; but, after all, they are exceptions, and surgeons must look for guidance to the rule. There must be some explanation of such an unusual occurrence, and we wish Dr. Michael had been able to give it.

A GALLANT ACT.

WE have great pleasure in recording an act of bravery and prompt action on the part of one of the junior members of the profession. On June 9th Mr. Frank Edward Nichol, assistant house-surgeon at St. Thomas's Hospital, was about to cross Westminster-bridge when his attention was attracted to a crowd on the Embankment and the presence of an old man in the river who was evidently drowning. Without hesitation Mr. Nichol ran down the steps, divested himself of his coat, and plunged from the parapet into the water. He had great difficulty in getting hold of the man, but managed to keep him above the surface until a boat arrived. Mr. Nichol's labours did not end here, for the man was pulseless and had ceased to breathe. It was necessary, therefore, to perform artificial respiration, in which Mr. Nichol was also successful. The man was admitted into the hospital, from which he was discharged quite well two days later. Such a deed is worthy of the highest praise, and we hope that Mr. Nichol will receive that recognition which it is in the power of the Royal Humane Society to bestow. We are pleased to add that no ill consequences have been suffered by the rescuer.

HOLIDAYS FOR THE OVERWORKED.

IN this hard-working age—and such it still is for very many, notwithstanding the long-continued depression of trade—the annual holiday has a continual interest, alike while it is expected or enjoyed and when it is remembered. That it is also in point of refreshment for mind and body an undoubted boon it is needless to assert. Almost everyone whose means permit now leaves town for a week or two of purer air than the rest of the year gives him. Each has his own ideal of what is recreation for him, but rest and variety are the components of every such ideal. In former articles upon this subject we have discussed its merits with our medical brethren and others in professional life, whose necessities in the matter of timely relaxation are well known. Now, we are happy to find that circumstances are so shaping themselves as to bring like holiday facilities within the reach of the labouring classes. These have not hitherto, for the most part, had either opportunity or means of arriving at what is to them a restorative at least equally

Digitized by Google

needful, but there is reason to expect that the former at all events will soon be obtainable. An article in the *Banner* suggests that rural clergymen should try to induce some of their wealthy parishioners to set apart one or two cottages for the use of shop *employés* released for a time from their duties in town. The idea is a good one, and if heartily taken up would meet an urgent want at no great cost to anyone concerned. Meanwhile, some employers of labour have taken a step in the right direction by arranging that each workman on their premises shall have in turn a week in each year for recreation without loss of wages. An extension of this custom is very desirable, and the week thus gained might, by a little self-help or by combination with the system of cottage-residence, be converted into a week in the country for artisans and their families. Even prudence teaches us that such measures, by invigorating those who form the backbone of our commerce and manufactures, must increase the contentment and prosperity of the whole population.

THE ELASTIC TISSUE TEST IN PHTHISIS.

THE plan of searching the sputum of phthisical patients for elastic tissue is so troublesome and disagreeable that it is not employed by practitioners in doubtful cases so often perhaps as it should be. A Russian observer, Dr. Opatski, has recently published the results of observations on more than a hundred phthisical cases in Professor Manassein's clinic, carried out with a view of determining the applicability of this method for diagnosing the disease. He divides the cases into three groups. The first, consisting of fifteen patients, comprised all those in whom the signs of phthisis were somewhat doubtful, six presenting no dulness; while in nine others, though flatness of the percussion note was detected, there was a lack either of bronchial breathing or of increased vocal fremitus, but not of both. In all fifteen elastic fibres were found, but the appearance was characteristic in twelve only, in the other three separate fibres merely being discovered. It is, however, remarkable that in all the six cases with the least phthisical signs characteristic elastic fibres were found. The second group contained twenty-nine cases, all of them presenting indubitable signs of phthisis—that is to say, dulness, bronchial breathing, and increased fremitus, or two of these signs at least; besides, in half of them there were moist râles. Here, again, elastic tissue was found in all, though in three there were only separate fibres. The third group of fifty-seven cases consisted of those in which there was more or less distinct evidence of cavities. Elastic fibres were found in fifty-five, all but one forming characteristic specimens, while in the exceptional case some separate fibres only were seen. In two cases no traces of fibres could be discovered. The sputum in these two cases was particularly foul, and the author throws out the suggestion that some ferment of the nature of trypsin may perhaps have been present in sufficient quantity to produce destruction of any elastic tissue which may have existed. In addition to the 101 cases included in the foregoing groups, there were two others undoubtedly phthisical, the sputum also containing elastic fibres, but intentionally omitted by the author because he was unable to detect any Koch's bacilli in them, and he had determined to include in his list only such cases as presented these micro-organisms. With regard to the question of correspondence between the number of bacilli and the quantity of elastic tissue, he was unable to find such close agreement as was described by Dettweiler and Meissen; still, in the majority of cases an abundance of elastic tissue was accompanied by a large number of bacilli. Thus a considerable quantity of elastic tissue was found in seventy-one cases, and in forty-nine of these the number of bacilli was also great, though in the rest it was not so, being described as "moderate" in fourteen, and "small" or "very small" in eight. In the two cases where there were no bacilli a fair quantity of elastic tissue was found. Ehrlich's method was used for bacilli, and the ordinary plan of boiling with potash as described by Bizzozero and Firket for the elastic tissue.

THE GAIT IN DISEASE.

FOR purposes of exact registration there is nothing to equal an automatic representation of the desired facts. The wetted foot in progression leaves a certain imprint on the ground of characteristic outlines; if this imprint has a particular shape for normal gait, we may naturally suppose that abnormal gaits will furnish varieties. This is the idea on which M. Gilles de la Tourette has worked in producing his "Études cliniques et physiologiques sur la Marche."[1] It is chiefly in diseases of the nervous system that he has employed this principle of registration, and some very curious figures testify to the peculiarities in the gait of individuals suffering from nervous affections. The bare soles of the feet were rubbed well with English red oxide of iron, and the patient walked on a long narrow strip of paper, in M. de la Tourette's experiments. As the hand in writing, so the foot in walking, leaves its trace; and we doubt not that the method employed by M. de la Tourette will prove useful in medical science

THE SEWERAGE OF RAMSGATE.

A PETITION to the President of the Local Government Board is in course of preparation in connexion with the sewerage of the borough of Ramsgate. In March, 1885, an inquiry was held, which led the Local Government Board to authorise the Town Council to borrow £20,000 to carry out a scheme designed by Mr. Baldwin Latham; and the petitioners declare that since then, the Corporation having in the meantime appointed their own surveyor to act as their "engineer" in the matter, serious departures have been made from the original scheme. These departures, it is contended, go to render the system much less efficient than it would have been under the original scheme, and in some respects very serious drawbacks are expected to ensue upon their adoption. It is also stated that Mr. Baldwin Latham has disclaimed all responsibility for the action which has been taken.

THE NATIONAL PHYSICAL RECREATION SOCIETY.

THERE can be no hesitation in admitting the advantage to the working classes which is likely to follow the formation of the National Physical Recreation Society. It is therefore satisfactory to observe that the aims of the Society are as extensive as they can well be. They will be directed to encourage athletic exercises among Board School children on the one hand and working men and boys on the other. The need of the Society's efforts is chiefly felt in the large towns, and these will therefore form the sphere of its operations. Town life has of late years undergone, or is undergoing, changes for the better which will fortunately promote the objects aimed at. Building is less close than formerly, open spaces have been laid out, even in the most crowded districts, and there is now a definite prospect that working hours will be subject to such limitations as will allow the worker a sufficient period of rest with some chance of morning or evening leisure for his own pursuits. The Society will do well to avail itself of the assistance which circumstances thus afford it in fixing the times and places for exercise. For example, gymnasia might be planted near the larger open spaces and a part of the

[1] Paris: A. Delahaye and Lecrosnier, 14, Rue des Carmes. 1886.

Digitized by Google

latter utilised for the erection of apparatus. Some time ago we advised that swimming should form a regular part of physical education. The young Society must, we fear, have considerable difficulty in assisting learners of this useful art. At the same time, if it did no more than advertise the locality of any baths adjacent to the various gymnasia, the convenience of members would be materially served. This organisation, we understand, will be as far as possible self-supporting, as it is most desirable that it should be. The sum of £1000 is necessary, however, in order to start the undertaking, and subscriptions towards this amount may be sent to the Society's offices, Northumberland Chambers, Northumberland-avenue, London.

INFLUENZA AT ST. PETERSBURG.

IN a discussion at a session of the St. Petersburg Medical Society on a severe epidemic of influenza which has this year affected the population of the city, it was stated by Dr. Petersen that towards the end of the attack many children had developed a kind of spurious whooping-cough, which, however, had terminated much more quickly than true whooping-cough generally does. Other complications of a bronchitic, pneumonic, ophthalmic, and dysenteric nature were described by different practitioners. Dr. Poehl mentioned that, having examined the urine in the cases of six of his own sons by means of Ehrlich's test a negative result only was obtained. Dr. Petersen had examined the thin nasal mucus in several cases, and had found multitudes of minute micro-organisms, frequently in chains; and though no cultures were made, he thought it more than probable that in influenza the active agent is of an organic nature. The treatment adopted was very various. In the cavalry school emetics and local applications of aqua laurocerasi, cocaine, &c., were adopted, while in the engineer school insufflations of bismuth and morphia were said to have produced satisfactory results.

THE PANIC ON THE HASTINGS PIER.

THE morals of the panic on the Hastings pier are two. First, it is supremely silly to allow oneself to be scared by what is almost known to be a false alarm, as was the case in this instance, the fact of a gun being fired being perfectly well known to everybody; and second, the officials in charge of any building have no sort of right to refuse or neglect to open the extra doors provided for exit in case of need, whenever and however a panic occurs. In the fright at the Pavilion on the Hastings pier the extra doors are said to have been purposely kept closed, and if this be the fact, a great mistake was made.

LITTER AND STRETCHER STATIONS.

THE Committee of the Ninth District of the St. John Ambulance Association has, on the recommendation of Surgeon-Major Platt, of the Volunteer Medical Staff Corps, established in the Kilburn District eight litter and stretcher stations, at all of which stretchers are kept in readiness for immediate use, in case of accidents, for the removal of injured persons to their homes or to the nearest hospital. In addition to the stretcher at the central station, a Furley litter, an invalid chair, and an ambulance hamper containing splints and other requisites for first aid, are kept, and at No. 2 a St. John Ambulance wheeled litter is stationed. These will all be available gratuitously in cases of accident; in other cases, when the use of a stretcher or litter is required, we presume a moderate charge will be made, and, on application to the superintendent, skilled bearers will be provided. The Committee has printed and distributed through the district a plan showing the position of the various stations at which the stretchers and litters are kept. The establishment of these ambulance stations cannot fail to be a great boon to the public, and we trust the example thus set may soon be followed in other districts of London and the suburbs.

REFUSAL OF A PROFESSORSHIP.

DR. L. KIRN, extraordinary professor in Freiburg, who had been elected by the medical faculty of Dorpat to the professorship of Psychiatry with charge of the clinic for mental diseases, has declined the invitation, preferring to remain in Freiburg. This can hardly be considered surprising if the rule which exists in Russian universities compelling professors to submit their lectures in manuscript to a police official several months before delivery is enforced in Dorpat, or at least in the medical faculty. There is, however, no doubt that professorships in Russian universities are not very comfortable posts at present, and that is the secret of the numerous resignations which are so constantly being announced. Resignations of chairs in our own universities are almost unknown, except on account of promotion or very advanced age.

BACTERIOLOGY.

THE great and increasing interest taken in the subject of bacteriology is well exemplified by the fact that a second edition of the work of MM. Cornil and Babès ("Les Bactéries," Paris: F. Alcan) has just appeared within twelve months of the publication of the first edition. Even in this short space of time much has been added to existing knowledge upon pathogenic micro-organisms, so that the authors of this work have found it necessary to make many additions to the text. We note also a decided improvement in the introduction of coloured illustrations into the text—there are no fewer than 348—instead of collecting them in a series of plates at the end of the volume. This mode of illustration—which was first adopted, at least on a large scale, in Dr. Woodhead's "Practical Pathology"—will, we hope, grow in favour; for there is no question as to its advantages for the reader.

NERVES FOR COLD AND HEAT.

PHYSIOLOGY is fertile ground for paradox. Menthol, a remedy for neuralgia, imparts a sensation of coldness to the skin on which it is rubbed. The part that has been rubbed with the menthol is, as a matter of fact, as ascertained by Dr. Goldscheider, hotter than the surrounding skin. This observation adds one more to the reasons already advanced, showing that the nerves which convey impressions of cold are at all events physiologically separated from those that conduct sensations of heat. Menthol is a powerful stimulant of the nerves conveying sensations of cold.

NEPHRECTOMY AND RESECTION OF LUNG.

A MAN, aged forty-nine, received a wound in the left side of the chest between the ninth and tenth ribs on August 30th, 1885. There was a hernial protrusion of the lung of the size of half a fist. Urine and blood flowed from the wound from the very first. Peritonitis developed and gradually became localised to the left flank. Inflammation of the protruded lung and phlegmon of the tissues around caused M. Demons to resect the pulmonary hernia by means of the thermo-cautery and écraseur eight days after the accident. Profuse offensive discharge, however, continuing, and the phlegmon not subsiding, M. Demons performed nephrectomy on September 26th, twenty-seven days after the accident. A vertical incision being made in the lumbar region gave vent to a large quantity of offensive matter, when the fascia of the quadratus lumborum had been incised. Considerable hæmorrhage followed the removal of the kidney;

Digitized by Google

suppuration continued for five months, and did not cease till a large sphacelus of connective tissue had been expelled. The case is interesting from a practical surgical point of view; unusual complications no doubt presented themselves, but the question remains whether the entire removal of the kidney was called for.

HIGH NURSING AND HYPODERMIC INJECTIONS.

THE lay press is happily, though alas that it should be necessary, calling attention to the inexpediency of allowing hypodermic needle apparatus to pass out of professional hands. It is one of the drawbacks of high nursing that trained attendants on the sick are not content to limit their ministrations to the simpler duties of preparing and administering food, giving medicine, &c., as specifically directed, dressing wounds, and generally tending the sick with gentleness and intelligence. We have again and again protested against the folly and, as we believe, danger of permitting nurses to carry and use hypodermic injectors. The use of the hypodermic syringe by non-medical hands ought, we are convinced, to be peremptorily and formally interdicted.

THE BRITISH MEDICAL ASSOCIATION.

THE fifty-fourth annual meeting of the British Medical Association will be held at Brighton on Aug. 10th and three following days. An address in Medicine will be read by J. G. Billings, M.D., of Washington; an address in Surgery by Mr. F. A. Humphry, surgeon to the Sussex County Hospital; and an address in Public Health by Dr. E. D. Mapother, consulting medical officer to the city of Dublin.

TWO NEW BURSÆ AT THE KNEE-JOINT.

M. POIRIER demonstrated, at a recent session of the Paris Anatomical Society, the existence of two new serous bursæ at the knee. They are situated, the one between the internal lateral ligament and the femur, the other between this same ligament and the tibia, and are separated from each other by the insertion of the internal ligament into the inter-articular cartilage. There is generally considered to be a prolongation of the articular synovial membrane at this point.

INDIAN HEMP IN DENTAL OPERATIONS.

INDIAN HEMP is recommended by Dr. Aarousin as an anæsthetic during dental operations. The tincture is diluted with from three to five times its volume, and applied by means of a plug of cotton-wool to the cavity of the tooth, and, in addition, is painted on the gum in the neighbourhood of the diseased tooth with a brush. The top of the tooth, too, may be similarly treated.

MR. JESSOP, whose injury by a carriage accident we noted in our last issue, is, we are glad to learn, recovering. The brougham in which Mr. Jessop was seated was broken up, and the injuries he sustained were undoubtedly reduced to a minimum by his presence of mind in retaining his seat instead of obeying the first impulse to leap out when the horses escaped from the control of the coachman.

A COMMITTEE of twenty-five members has been appointed in Vienna for the purpose of making arrangements for the forthcoming International Congress to be held there in 1887.

A COURSE of Bacteriology is announced to be given in Madrid by Don Santiago Garcia Fernandez, who has studied in Berlin and Munich.

DURING the remainder of the Summer Session, lectures on Diseases of Children will be delivered at the Children's Hospital, Great Ormond-street. A prospectus of these lectures can be obtained by application to Dr. Sturges or the Secretary at the hospital. The lectures are not intended for students only, but also for practitioners. The practice of the hospital is likewise open free to practitioners and senior students. Two lectures by Mr. Cartwright will be delivered on "Lesions of Dentition, their Surgical and Mechanical Treatment," on June 16th and 23rd, at 9.30. Dr. Lubbock will deliver two lectures on "Diseases of the Respiratory Organs in Children" on June 25th and July 2nd, at 3.30 P.M. Dr. Sturges will lecture on July 7th, at 3.30 P.M., on "Body Heat in certain Diseases of Childhood and its Significance." The Children's Hospital thus bids fair to become a centre for teaching on diseases of childhood. Already the hospital has been well attended by both practitioners, including medical men from the colonies, and students. The development of a school for teaching diseases of children systematically is a need in London, and the effort made by the staff of Great Ormond-street Hospital deserves every encouragement.

THE success which attended the action of the Council of the Sanitary Institute of Great Britain in publishing an abstract of the late Dr. Farr's works, and the approval which that volume has obtained from workers in hygiene, have led the Council to undertake the publication of the writings of Mr. John Simon, C.B., F.R.S., formerly medical officer to the Privy Council and Local Government Board. Many of Mr. Simon's papers are of immense importance at this juncture, when various social questions connected with the housing, occupations, and feeding of the poor are coming into the field of practical politics, and we heartily wish the Council success in the execution of their design. Dr. Edward Seaton has been chosen as editor, and the work will be revised by the author.

ON June 16th, Dr. Acland gave a demonstration at the Brompton Consumption Hospital of the micro-organisms found in diseases of the lungs. He exhibited a large number of cultivations as types of various species of organisms, as well as microscopical specimens of aspergillus mycosis, woolsorters' disease (anthrax), septic pneumonia, pus from empyema, diphtheritic membrane, and actinomycosis of the lung in man and animals. The next demonstration will be on June 26th, at 4 P.M., when the organisms found in pneumonia and tubercle will be shown, and the subject will be illustrated by many of Dr. Crookshank's micro-photographs.

THE *Journal of Reconstructives* is the title given to a quarterly publication dealing entirely with dietetics, the only paper in the world devoted to this subject. The current number contains an article by Dr. Milner Fothergill on "The Dietary in Digestion," and one by Dr. W. S. Playfair on "Constitutional Treatment in certain forms of Disease in Women."

THE health of the British troops quartered at Assouan and at other stations up the Nile is very unsatisfactory. No less than 150 deaths are stated to have occurred lately from enteric fever and heat apoplexy, while 710 invalids were under orders to leave for Cairo on the 17th inst.

THE Paris Academy of Sciences having to appoint a successor to M. Desseignes, late corresponding member in the chemical section, has shown its large-heartedness in nominating in the place of the deceased French *savant* a German, Dr. von Baerger, Professor of Chemistry in Munich.

Digitized by Google

IT is reported that "black fever" is raging in the upper part of Rhondda Vach Valley. During the last fortnight there have been 160 cases, and 21 patients have already died. Scarlet fever is also stated to be extremely prevalent in the same locality.

DURING a stay of eight weeks in Meran, Duke Theodor of Bavaria is stated to have attended more than a thousand ophthalmic patients, and to have performed 132 major eye operations.

BY the capsizing of a yacht on the Severn on the 15th inst., Dr. Davey, surgeon of the Severn Tunnel works, was drowned.

PROFESSOR BIRCH HIRSCHFELD, of Leipsic, has been obliged by severe illness to leave the university, and is gone to Reichenhall.

PROFESSOR VON LANGENBECK, who has been nearly blind from cataract, has been operated on successfully by Dr. Pagenstecher in Wiesbaden.

THE French Senate have agreed unanimously to the vote of 200,000 francs for the Pasteur Institution.

IRISH MEDICAL ASSOCIATION.

THE annual meeting was held on the 7th inst., presided over by Dr. Edward Hamilton. The report of the Council referred to the Medical Bills now before Parliament, and stated that their principles and provisions, so far as they went, were in complete accord with the views of the Association. The Bill introduced by Mr. Mayne to amend the Labourers' Act made no provision for remunerating medical officers for inspecting cottages and reporting on the same; but the Association obtained the addition to the Bill of a new clause giving remuneration to medical officers of health under its provisions. The Government Bill to allow compensation to Poor-law officers upon abolition of office was merely permissive, not mandatory, and the Council were therefore thoroughly dissatisfied with its provisions. In the House of Lords an amendment to have the desired effect was passed, but when sent back to the Commons for approval the word "salary" was struck out, the clause being thereby greatly reduced in value to all Poor-law officers. The report also drew attention to the question of revaccination, and to substitutes for prison surgeons under certain conditions.

The following resolutions were adopted:—

"That the Medical Acts Amendment Bill recently introduced to Parliament, though it fails to deal with the unqualified practice of medicine and is deficient in other respects, is yet in conformity with the declared policy of the Association, and is therefore, so far as it goes, deserving of its approval and support."

"That this Association strenuously protests against the injustice done to union medical officers by depriving them of their means of livelihood upon abolition of office consequent upon the amalgamation of unions, without securing to them provision for their compensation. That such method of dealing with these officers is at variance with the custom of the public service, and a great hardship upon them."

"That it is indispensable to the efficiency of the Poor-law Medical Service that the issue of medical relief tickets shall be limited to deserving cases, and that, with this object, some means of cancelling improperly issued tickets should be provided more effective than that which the existing system offers. That the Council be directed to promote an amendment of the law on the earliest favourable opportunity."

Dr. Hamilton having left the chair, and Dr. Kinkead, the new President, having been called thereto, a vote of thanks was passed to the outgoing President for his services during the past year. The annual dinner took place in the evening in the Albert Hall of the College of Surgeons.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5699 births and 3927 deaths were registered during the week ending June 12th. The annual death-rate in these towns, which had steadily declined in the preceding twelve weeks from 29·3 to 17·0 per 1000, was last week 17·4. During the first ten weeks of the current quarter the death-rate in these towns averaged 19·1 per 1000, and was 3·1 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 9·0 in Brighton, 12·4 in Cardiff, 13·1 in Birkenhead, and 13·6 in Derby. The rates in the other towns ranged upwards to 24·8 in Manchester, 25·4 in Wolverhampton, 26·4 in Blackburn, and 34·5 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 278 and 279 in the preceding two weeks, declined last week to 265, a lower number than in any previous week of this year; they included 89 from measles, 60 from whooping-cough, 47 from diarrhœa, 28 from "fever" (principally enteric), 23 from scarlet fever, 18 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Norwich or in Plymouth; whereas they caused the highest death-rates in Portsmouth, Bolton, Blackburn, and Preston. The greatest mortality from measles occurred in Bolton, Blackburn, and Preston; from whooping-cough in Portsmouth and Derby; from "fever" in Preston, Portsmouth, and Huddersfield; and from diarrhœa in Preston, Cardiff, and Blackburn. The 18 deaths from diphtheria in the twenty-eight towns included 11 in London and 3 in Portsmouth. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 35 and 25 on each of the preceding two Saturdays, had risen again to 29 at the end of last week; 9 new cases were admitted to these hospitals during the week, against 10, 6, and 4 in the preceding three weeks. The Highgate Small-pox Hospital contained 2 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding twelve weeks from 917 to 179, rose again last week to 216, but were 48 below the corrected average. The causes of 72, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Nottingham, Portsmouth, Salford, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Sunderland, Huddersfield, Halifax, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined in the preceding six weeks from 23·1 to 20·9 per 1000, was again 20·9 in the week ending June 12th; this rate, however, exceeded by 3·5 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 14·8 in Leith and in Perth to 22·5 in Edinburgh and 22·9 in Glasgow. The 516 deaths in the eight towns showed an increase of but one upon the number in the previous week, and included 19 which were referred to whooping-cough, 10 to measles, 7 to diarrhœa, 6 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 3 to diphtheria, and not one to small-pox; in all, 49 deaths resulted from these principal zymotic diseases, against 60 and 68 in the preceding two weeks. These 49 deaths were equal to an annual rate of 2·0 per 1000, which exceeded by 0·5 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 11, 17, and 21 in the preceding three weeks, fell last week to 19, of which 6 occurred in Edinburgh. The 10 deaths from measles showed a decline of 9 from the number in the previous week, and included 8 in Edinburgh and 2 in Leith. The 7 deaths attributed to diarrhœa were fewer than those in recent weeks, and were 6 below the number in the corresponding week of last year. The 6 fatal cases of scarlet fever corresponded with the number in the previous week; 4 were returned in Glasgow

Digitized by Google

The deaths referred to "fever," of which 2 occurred in Edinburgh, showed a decline from recent weekly numbers. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 86 and 90 in the previous two weeks, rose again to 90 last week, and were 4 below the number in the corresponding week of last year. The causes of 80, or 16 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·7, 26·0, and 26·2 per 1000 in the preceding three weeks, declined to 20·8 in the week ending June 12th. During the first ten weeks of the current quarter the death-rate in the city averaged 26·3 per 1000; the mean rate during the same period did not exceed 17·7 in London and 19·5 in Edinburgh. The 141 deaths in Dublin last week showed a decline of 36 from the number in the previous week, and included 5 which were referred to the principal zymotic diseases, against 6 and 9 in the previous two weeks; 4 resulted from whooping-cough, 1 from diarrhœa, and not one either from small-pox, measles, scarlet fever, diphtheria, or "fever." These 5 deaths were equal to an annual rate of 0·7 per 1000, the rates from the same diseases being 1·5 in London and 4·1 in Edinburgh. The fatal cases of whooping-cough, which had been 2 and 3 in the preceding two weeks, further rose last week to 4. Five inquest cases and 6 deaths from violence were registered; and 41, or more than a quarter of the deaths, were recorded in public institutions. The deaths of infants were more numerous, while those of elderly persons were fewer, than in any previous week of this year. The causes of 15, or nearly 11 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

INDIA OFFICE.— THE Queen has approved of the following, amongst other promotions made by the Governments in India:—Brigade Surgeon William Frederick de Fabeck, M.D., of the Madras Medical Establishment, to be Deputy Surgeon-General; Surgeon-Major Joseph Francis Barter and Surgeon-Major Hugh Griffith, of the Madras Medical Establishment, to be Brigade Surgeons; Surgeons John Lane Corbett, M.D., Samuel Haslett Browne, M.D., Edward Mair, James Armstrong, Louis Richard Dawson, M.D., Horace Parr Yeld, John Campbell Fullerton, and Charles James Hislop Warden, of the Bengal Medical Establishment, and Surgeons David Aikman Patterson, M.D., James Sutherland Wilkins, and William Alexander Barren, of the Bombay Medical Establishment, to be Surgeons-Major.

ADMIRALTY.—The under-mentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet:—Edward William Doyle and George Kell.

The following appointments have been made:—Surgeon James Porter, to the *Impregnable;* Surgeon Henry E. Beatty, to the *Calypso;* and Henry Gramshaw, to be Surgeon and Agent at Walton-on-the-Naze.

YEOMANRY CAVALRY.—North Somerset: Surgeon John J. Saville is granted the honorary rank of Surgeon-Major.

ARTILLERY VOLUNTEERS.—1st Worcestershire: Charles Horace Barkley, Gent., to be Acting Surgeon.—1st Cumberland: Charles Maculloch, Gent., to be Acting Surgeon.

RIFLE VOLUNTEERS. — 4th Volunteer Battalion, the Essex Regiment: Surgeon John Vance, M.D., is granted the honorary rank of Surgeon-Major.—2nd London: Surgeon E. Sandwell is granted the honorary rank of Surgeon-Major.—2nd Volunteer Battalion, the South Staffordshire Regiment: Acting Surgeon E. T. Collins resigns his appointment.—1st Cadet Battalion, the Royal Warwickshire Regiment: Francis William Underhill, Gent., to be Acting Surgeon.

AT a meeting on behalf of the Convalescent work of the Charity Organisation Society, held recently, it was reported that there are now 110 homes working in co-operation with the Society, and that in the past year 2116 cases had been dealt with. The average cost of a bed for a year, *plus* 10 per cent. for working expenses, is £28 10*s.*; of a "summer" bed, £15.

Correspondence.

"Audi alteram partem."

WHOOPING-COUGH.

To the Editor of THE LANCET.

SIR,—I ask for space to refer shortly to the paper on whooping-cough (by Dr. W. H. Barlow of Manchester) which appeared in your impression of May 8th. A case reported by me is there quoted from Dr. Sturges' recent lectures on "Disease in Early Life" (*Medical Times and Gazette*, July, 1885); and as Dr. Barlow alludes to me as a competent observer, I desire to try to show myself somewhat more worthy of that name than I should be if my case were to be read in the light of Dr. Barlow's comment thereon.

The case was meant to illustrate the important and moot question—Does pertussis ever arise directly out of catarrh? Two children developed pertussis five weeks after the onset of scarlatina, during *isolation* (of which I gave the details that appear in Dr. Barlow's quotation). The point of the case is that the children fall ill with scarlatina, are immediately isolated and surrounded with the regulation antiseptic appliances, develop bronchitis, and five weeks after the beginning of the isolation develop typical pertussis. This point is of course lost if the isolation can be shown to be as fictitious as is suggested by Dr. Barlow, who says (1) there was a nurse there; (2) the strange medical man and the father *may* have visited cases of pertussis; (3) a neighbour's child *may* have been admitted into the room. I would repeat that *no one else* saw the children except those mentioned in my report; neither of the doctors (the father and myself) had seen a case of pertussis during the time alluded to; and the nurse who had been with the children from the beginning of the fever had sole charge of them night and day, and was perfectly well the whole time. Had these facts not been established the case would not have deserved notice at all. With regard to the "carbolic acid sheet" and vapour, I merely mentioned these to show that the usual precautions were taken which are believed in by those who practise according to the creed of microzymosis. For myself, I agree with Dr. Barlow in thinking them of no probable value. Of more importance is the fact that the two rooms (at the top of the house) were regularly ventilated by open windows.

What, I think, my case shows is that convulsive cough may develop out of a catarrh where the absence of a specific contagium is as demonstrable as any negative evidence can make it, and in the presence of the recognised clinical antiseptics which the profession has taught the public to trust in. I would add to the report of this case that the pertussis developed from ten to twelve days after the symptoms and signs of bronchitis; so that Dr. Barlow's belief in the definite fourteen days' incubation of pertussis would exclude the possible objection that the infection may have been received before the scarlet fever was recognised. In my opinion, however, such an objection would be stronger than all Dr. Barlow's suppositions, for it could not be so easily traversed. I believe that there are many cases which *must* be called pertussis (if we read them from symptoms alone) that do not spread. I have repeatedly observed this, especially in hospital practice, and in cases in families where there are presumably unprotected children obnoxious to the hypothetical contagium. This, however, is too large a subject to touch upon in a letter. Dr. Barlow admits that whooping-cough does not spread at Pendlebury, but says it is because the cases are soon sent out, and the contagium is less virulent in the early stage. But Dr. Bristowe, a strict contagionist (and with him here are most clinical observers, whatever their creed), teaches that the contagium, whatever it is, is most active in the early stage, and before the characteristic cough is developed. The number of cases of pertussis, or convulsive cough, following immediately on measles—the pre-eminently catarrhal malady—is certainly overwhelming; and I feel sure that, whatever this connexion may mean, clinical statistics taken on this point would show a close sequence unparalleled by any other pair of zymotic diseases.

I am, Sir, yours truly,

London, June 1st, 1886. H. B. DONKIN.

TUBERCLE BACILLI IN ADDISON'S DISEASE.

To the Editor of THE LANCET.

SIR,—In your last week's number there is an interesting note on the discovery of tubercle bacilli in the supra-renal capsules in Addison's disease. I should be obliged if you will permit me to point out that in a clinical lecture at King's College Hospital last month I showed the enlarged and caseated capsules in a well-marked and fatal case of Addison's disease, and told my class, that after repeated and most careful examinations for the special object of detecting tubercle bacilli, one of our best modern microscopists and bacteriologists had failed to find any bacilli. It is therefore clear that in this respect, as in some others, cases of Addison's disease differ, and that we must not too hastily assume that it is always a strictly tubercular affection.

I am, Sir, yours, truly,

George-st. Hanover-sq., June 14th, 1886. JOHN CURNOW.

ELECTROLYSIS IN STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—There are one or two points raised by Mr. Hurry Fenwick in THE LANCET of June 5th to which I must venture to take some exception. He implies in his first paragraph that the currents I was using were strong currents, and in his second speaks of their burning the cicatrix. With regard to the first point, I can only say that the currents I used were very weak, and they caused no pain. I could very easily bear them on my own skin; and with regard to the second, I can positively assert that they do not burn. I have always been careful to point out that the object to be attained was softening of the tissues and gradual chemical change, not cauterisation. That a caustic alkali is liberated in the urethra is quite true; but it is only in small amount, and I do not believe this represents by any means all that takes place. Of the value of electricity in certain cases of stricture I have no doubt, but what we now require to know is what is the nature of the changes that take place in certain tissues under varying current strengths, a point which I am at present engaged in investigating. This question could never be answered till we had some ready means of measuring current strengths; this means we now possess in the voltmeter. With regard to "reflex shock," excepting in the first case in which I used electricity, when of course my experience was *nil*, I have never had a rise of temperature or any constitutional disturbance, and I am confident that in the electric current we have a safe and certain therapeutic agent.

I remain, Sir, yours faithfully,

Harley-street, June, 1886. W. BRUCE CLARKE.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The Council of the University of Durham College of Medicine desire me to draw your attention to the following statement in answer to certain observations made by Sir John Lubbock and Professor Sir Henry Roscoe during the discussion on the Medical Acts Amendment Bill in the Committee of the House of Commons on Monday, the 31st ult. Sir John Lubbock is reported to have stated that "he should say there were not more than twenty or thirty medical undergraduates at the Durham University." As a matter of fact the medical undergraduates in attendance at the University during the last year (1885) numbered 234 (see the University Calendar, 1886), of whom many were already qualified to practise; and the number of individual entries for the examinations for the degrees in medicine (excluding those for the special arts examinations for the degrees in medicine) during the period from May 1st, 1885, to April 30th, 1886, was 245. Of this number, 186 passed the various examinations for the degrees, of whom 63 graduated, 42 passed the first examination (old regs.), 54 the first examination (new regs.), and 27 the second examination (new regs.).

I am, Sir, yours faithfully,

LUKE ARMSTRONG, M.D.,

June 14th, 1886. Regist. Univ. of Durh. Col. of Med.

THE POISONOUS EFFECTS OF COCAINE.

To the Editor of THE LANCET.

SIR,—Under the above heading there appears a letter in THE LANCET of June 12th, in which a case is related with symptoms of poisoning after the free application of from twenty to thirty drops of a 4 per cent. solution of hydrochlorate of cocaine to the teeth and gums. It may be interesting to your readers to mention a case of ulceration at the back of the tongue of so painful a nature that it has necessitated the frequent application of a 20 per cent. solution of cocaine, so that for the past month about two drachms of the 20 per cent. solution, that is twenty-four grains, have been applied to the back of the mouth and throat in every twenty-four hours without any untoward constitutional symptoms. The pain of swallowing has been so great that the cocaine has had to be freely used to deaden sensibility previously to taking nourishment. The only untoward effect I have noticed is some interference for a short time with the act of deglutition when the cocaine is brought too freely in contact with the palate. The sensitiveness of the palate is interfered with, and reflex action, a necessity of deglutition, destroyed for a brief period. Power is soon regained, but insensitiveness to pain continues for some time afterwards. Cocaine solutions are known to have an exceptional disposition to favour the development of germ life, and should always be freshly prepared for use, or some unexpected action may be produced.—I am Sir, yours obediently,

Wokingham, June 16th, 1886. J. G. BARFORD.

BIRMINGHAM.

(From our own Correspondent.)

THE BOARD OF GUARDIANS AND THEIR MEDICAL OFFICER.

THE relations between the guardians and their medical officer have been strained for some months past, as already noted in THE LANCET. An inquiry was held by the Local Government Board, and at a meeting of the guardians held on March 31st a letter was read from the central authority calling upon the medical officer to resign his appointment. Since this time an endeavour has been made to prevent the resignation taking effect, and to create a reaction in favour of the official. On the principle that the punishment was greater than demanded by the alleged error, a memorial was signed by a number of influential members of the Board of Guardians, asking for the question to be reconsidered on the ground of the long period of sixteen years' service on the part of the medical officer, with singularly few complaints and a faithful discharge of duty. A special meeting of the guardians was held on the 16th inst., and the majority affirmed the resolution of the Local Government Board. Thus, after much criticism and discussion, a valuable officer is forced to take his departure under circumstances which considerably mar his chances in the future, and at a time of life when it is difficult to make a fresh start in practice, after a long period of routine work to which he devoted his best years and abilities in the performance of an ungrateful task.

HEALTH OF THE BOROUGH.

The able report of the medical officer of health for the year 1885 gives a very favourable account of the sanitary condition of this large town, and points out that the absolute number of deaths is less, with two exceptions, than in any year since 1870. This is rendered much more gratifying by the facts elicited, that there is a diminished mortality in infants under one year of age, and in children under five years of age; and also a lessened mortality from zymotic or preventable disease. A higher death age, too, than has been observed in previous years is worthy of comment. Comparison shows that whilst the density of Birmingham is exceeded by only four of the large towns, and is considerably greater than the other seven taken for the estimate, its death-rate is least of all. At the present rate of improvement, the inhabitants may take comfort in the knowledge that smoke and dirt were not the essential elements of the mortality of manufacturing towns.

REMARKABLE CASE OF POISONING.

The coroner for Central Warwickshire held an inquest touching the death of a child aged five years on June 15th.

Digitized by Google

It appears that one day the child ate largely of green sorrel without apparent harm. The following morning, awakening early with a strong feeling of thirst, he drank freely from a jug containing soap-and-water, with the immediate accession of alarming symptoms, unconsciousness, and death on the next day. The post-mortem examination revealed the fact that the alkali of the soap-and-water had set free the oxalic acid contained in the green sorrel, and that death had resulted from this cause. If this theory be correct, it indicates a singular and exceptional form of poisoning; it would have been interesting also to have had some definite opinion as to the injurious qualities contained in the soap-and-water mixture, and a separate analysis of this might have thrown additional light on this somewhat obscure and startling case.

Birmingham, June 16th.

LIVERPOOL.

(From our own Correspondent.)

MORTALITY OF INFANTS IN THE LIVERPOOL WORKHOUSE.

AT the last meeting of the Workhouse Committee of the Select Vestry, a return was handed in by the master of the infant mortality for two years. This showed that in the year ending February, 1884, there were 257 deaths of infants; of these, 167 were under two years of age, 48 between two and seven years, 8 between seven and ten, and 14 between ten and fourteen. In the year ending March last, there were 230 deaths of juveniles, of whom 194 were under three years of age, 23 between three and seven, 6 between seven and ten, and 7 between ten and fourteen. It was resolved that Fulwood Lodge, a large country house, most healthily situated, should be taken, and appropriated for the infants in the workhouse, with a view of seeing whether the infant mortality might be reduced. It was estimated that the cost of the house would be about £250 a year. This decision of the committee must be considered extremely satisfactory, indicating the most humane interest in the welfare of the class committed to their charge, it being too much the fashion now to underrate such questions as the mortality of pauper infants.

HOSPITAL SATURDAY.

The returns up to the 11th show a total of £2704, which it is hoped will be increased to a large sum when all the returns have come in. At many of the places where large numbers of men are employed it has been the practice lately for the men to contribute to the fund periodically throughout the year.

THE HEALTH OF THE CITY.

The rate of mortality was stated at the last meeting of the Health Committee to be 19·8 per 1000. The following cases of infectious disease were reported—fever, 11, of which 10 were removed to hospital; small-pox, 3, all of which were removed; scarlatina, 18, of which 6 were removed; measles, 22, of which 1 was removed. In the City Small-pox Hospital 5 patients were admitted during the week, 4 were discharged, and there are now 20 in-patients.

DEATH OF MR. BENJAMIN BLOWER, M.R.C.S.

Another veteran practitioner of Liverpool has passed away in the person of Mr. Blower, who died on the 12th inst., at the advanced age of seventy-three. He was the first house-surgeon of the Northern Hospital, holding that office from its opening in 1835 until 1838, several years before the erection of the present building. Subsequently he became surgeon to the Ladies' Charity and Lying-in Hospital, to which he was consulting surgeon at the time of his death. He was the inventor of the "slipper bedpan" in 1836, and of the portable leg-cradle in 1870; he was also the author of an interesting account of the "Mersey, Ancient and Modern." Advantage has been taken of the occasion of his decease and burial to inaugurate a most sensible reform, the obituary announcement having, in addition to the usual intimation to friends, the very significant addition, "No wreaths."

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH.

In addition to the work done by the medical officer of health in the improvement of insanitary property alluded to in THE LANCET of last week, his annual report gives many other very interesting details. There were 938 persons removed to hospitals, the greater number being taken to the parish infirmary at Brownlow-hill, the Fever Hospital in Netherfield-road, and the City Hospital for Infectious Diseases at Park-hill. There were 61 bodies removed to mortuaries, 11 of these being taken to the Toxteth cemetery, and 50 to the parish mortuary of St. Martin. Under the Adulteration Act there were 175 prosecutions, the result being that 8 cases were dismissed with a caution or withdrawn, and in 167 cases penalties were inflicted varying from 5*s.* and costs to £5 and costs, amounting in all to £301 14*s.* 1*d.* Four informations were laid for refusing to sell samples of milk, 2 were fined 10*s.* and costs and 2 acquitted. The unwholesome meat seized and destroyed amounted to nearly 70 tons, and of fish to 71½ tons. The number of articles disinfected at the apparatus during the year was 39,149, while 1099 articles were destroyed.

THE LOCK HOSPITAL.

Referring to a paragraph which recently appeared in THE LANCET respecting this hospital, it is gratifying to be able to report that Mr. F. W. Lowndes received from various friends a sum not only sufficient to frame and glaze all the engravings so kindly given by the proprietors of the *Graphic*, but also to leave a balance in hand. On the suggestion of Dr. Bernard, this was devoted to the purchase of a bagatelle-board, he having remarked how very popular that game was at the Sailors' Home. This kindly and generous feeling towards patients for whom so little sympathy is generally displayed is worthy of all praise.

Liverpool, June 15th.

MANCHESTER.

(From our own Correspondent.)

HEALTH OF MANCHESTER.

THE biennial report of the medical officer of health for the city has just been presented to the Council, and contains much matter for reflection by all sanitarians. Our infantile mortality is still highly unsatisfactory, and the deaths of children during 1885 under five years of age was 40 per cent. of the total, whilst in some of the subdistricts it was considerably over 50 per cent. Our death-rate for the past year, according to the officer of health's calculations, was 24·7 per 1000, but on the Registrar-General's figures it was 25·3; so that our death-rate still has an unenviable pre-eminence among the large towns. The deaths from the chief zymotics during the past year—viz., small-pox, measles, whooping-cough, fever, and scarlet fever—was equal to a rate of 2·2 per 1000.

COUNTRY TRIPS FOR TOWN-BRED CHILDREN.

As a practical step in endeavouring to give our town-bred children a little more life and vitality, none deserves more encouragement than the work undertaken by voluntary workers to send as many as possible for a three weeks' holiday into the country. This year another branch of this same work is hoped to be put in operation, and to reach the very lowest of our waifs and strays; these it is proposed not to send into the homes of country people, but to take in batches to the seaside, and there keep them a week or two under canvas in tents.

THE VICTORIA UNIVERSITY.

The deputation that recently waited on Earl Spencer, the Lord President of the Council, to support a memorial asking for an annual grant of money from the national exchequer, in aid of the funds of the Victoria University, was of a most influential and representative character, consisting of members of Parliament of this and the adjoining county of every shade of politics, the heads of Owens College, University College, Liverpool, and the Yorkshire College, Leeds, the Bishop of Chester, Earl Derby, the Duke of Devonshire, and other noblemen. Earl Spencer, as was to be expected, gave a very guarded reply. Alluding to the fact of the Government having granted funds to other universities, he admitted that the plea of poverty had always had great weight, but he did not think that Manchester and its district could plead that it was very poor. He promised that when the case came before the Government he would give it all the support he could.

AID TO HOSPITALS.

The Hospital Sunday and Saturday Fund has recently been allotted to the various hospitals, and, as is usual, one hears a little murmuring that the wealthy charities should receive in the same proportion as the poorer and struggling ones.

NOTIFICATION OF INFECTIOUS DISEASES.

The last meeting of the North-Western Association of Medical Officers of Health was spent in a visit to the Fever Hospital, disinfecting station, sewage works, &c., of the adjoining borough of Salford. In the course of an address delivered by Dr. Tatham, the officer of health, he spoke in unqualified terms of the system of notification of infectious disease, and suggested that the time had come when it ought to be made compulsory throughout the country. As an additional argument in support of this proposition might be cited the fact that many of our surrounding districts have endeavoured to put in action the same system without compulsory powers, the local board of Moss Side being the last to offer a fee of 2*s.* 6*d.* for each certificate received from medical practitioners.

THE BRITISH ASSOCIATION MEETING.

Preliminary steps have been taken in connexion with the meeting of the British Association that is to be held here in 1887, over which Sir Henry Roscoe is to preside. Unfortunately, a note of discord has been heard in complaints from certain members of the Association that these preliminary proceedings have been kept too exclusively in the hands of those connected with Owens College, and that those outside its pale have been quietly ignored. It is to be hoped that this will all be set right, and that nothing will be done which shall in any way interfere with the harmony and successful issue of the Manchester meeting.

OUR NEW BISHOP.

The Bishop has produced a very favourable impression in his new diocese, and, like his predecessor, has shown his interest in practical schemes for the amelioration of the condition of the masses of our people. One of the first offices he accepted was the presidency of the Manchester and Salford Sanitary Association, formerly held by Dr. Fraser.

Manchester, June 7th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

UNIVERSITY OF DURHAM.

THE entries for examinations for degrees in the Faculty of Medicine, which commence in Newcastle on the 21st inst., are unusually large, and will give some work to the examiners. The number of candidates for the degree of Doctor of Medicine for practitioners of fifteen years' standing is 12; for the degree of Doctor in Medicine (Essay), 8; for the degree of Master in Surgery, 7; for the final examination for the degree of Bachelor in Medicine, 50. The Arts examination will be held by the Rev. H. J. Richmond, M.A., and the Rev. J. T. Fowler, M.A. The extra examiners are Professor Buchanan and Dr. Ralfe.

OPENING OF PUBLIC BATHS.

The Mayor of Newcastle opened the new baths in Scotswood-road, in the neighbourhood of Sir William Armstrong's works, last week. This completes the set of very fine buildings erected for the public by our corporation, and about which I gave you some information a few weeks ago; but the Elswick Baths, as they are called, have been delayed owing to difficulties in finding proper foundations for the structure. They have cost about £10,000. The mayor stated that though the other baths have been opened but a few weeks, they had been used by nearly 22,000 persons.

PHOSPHORUS POISONING.

At Ovingham, a village a few miles from Newcastle, an inquest has been held on the body of a woman, aged thirty, who died from the effects of poisoning by phosphorus. It appears she had been in a depressed state of mind for some time, and fancied herself *enceinte*. Dr. Bulleid, of Ovingham, who attended the deceased, deposed to her having suffered from the usual symptoms of phosphorus poisoning. She had confessed to her mother to having taken the phosphorus of three boxes of lucifer-matches. The post-mortem proved that the deceased was labouring under a delusion in thinking herself *enceinte*.

A NORTHERN GIANT.

A man named Allender died last week at the South Shields Workhouse, who was known as the "Irish Giant." The deceased was a native of Londonderry, Ireland. He was 7 ft. 6 in. in height, and weighed 27 st.

MEASLES AT WALKER.

A serious epidemic of measles is reported at Walker-on-Tyne. No less than 159 children attending the Walker schools are laid up. It is the third year that a similar outbreak has taken place. On Friday last 182 children were absent from school, mainly on account of the disease.

Newcastle-on-Tyne, June 14th.

EDINBURGH.

(From our own Correspondent.)

DR. OLIVER WENDELL HOLMES.

DR. HOLMES, the genial author of "The Autocrat" and other volumes of the "Breakfast-table" series, is about to visit Edinburgh, where his reception will, to all appearance, be not one whit less cordial than it has been in the English academic centres he has visited. Not only is he to be *fêted* and lionised by the social world in Edinburgh, but he has signified his acceptance of the honorary degree of LL.D. which has been proffered him by the Senatus Academicus of the University of Edinburgh, and which it is intended formally to confer upon him on the 25th inst. The Students' Representative Council have under consideration how they may most suitably accord a hearty welcome to the distinguished Professor, and it has been suggested that a symposium should be held in his honour, supported by the whole body of the students. If this plan should prove acceptable to Dr. Holmes, it will be immediately promoted with a zeal which, as former occasions have amply proved, will ensure the complete success of the project. It is anticipated that Dr. Holmes's arrangements will permit of his paying an extended visit to the Scottish capital, in connexion with which a widely-felt interest has been manifested, and an equally extended desire to catch a glimpse of him while he is here.

EDINBURGH UNIVERSITY BUILDING FUND.

There has been considerable interest during the last few days attaching to a rumour that has been widely circulated, and that has found its way into print in several of the public journals, to the effect that a large sum of money, sufficient to cover the total expense involved, had been placed at the disposal of the Building Committee for the completion of the new University medical buildings on the plans originally drawn up. This rumour has as yet received no official confirmation; but it has the greater semblance to fact on account of the name of the generous donor being that of an Edinburgh citizen to whom the University is already largely indebted for sums of money applied to similar purposes. The sum now required for the purpose in question exceeds £50,000. The present uncertainty as to this rumoured donation will probably be cleared up within the next few days.

SIR DOUGLAS MACLAGAN, M.D.

An influential committee of Edinburgh gentlemen, representing a very wide circle of interests, professional and otherwise, have undertaken arrangements by which Sir Douglas Maclagan's numerous friends and admirers may have the opportunity of conveying to him, in a tangible form, a suitable expression of the high esteem in which he is held. It is proposed that the veteran professor, scientist, and jurist shall be presented with a marble bust of himself, accompanied with an address embodying the sentiment which has called forth this manifestation of respect, and conveying the cordial congratulations of those whose names it bears upon the recent recognition on the part of Her Majesty of his eminence in the varied fields in which he is a worker, an eminence fittingly recognised by the bestowal of

Digitized by Google

knighthood upon him. A printed notice, emanating from the executive committee appointed for the purpose, is in process of circulation amongst medical and other professional men trained in the Edinburgh school. In this notice exact particulars of the proposed procedure will be found. The name of Dr. George A. Gibson, Sec., R.C.P.Ed., is mentioned in the notice as treasurer for the presentation fund.

A ROYAL MEDICAL STUDENT.

The University of Edinburgh numbers amongst the names of its matriculated students that of one of the native Indian princes who rule over the independent territories in Hindustan. His Highness the Thakoor Sahib of Gondal, one of these independent rulers, is at present engaged in the study of medicine and natural science, being impressed with the importance of such studies in relation to the wise government and development of the resources of his country. He will probably not complete the course of studies requisite for obtaining a degree in medicine, but several of the more important of these will claim his attention during the two years which he thinks of spending in Edinburgh.

Edinburgh, June 15th.

BELFAST.

(From our own Correspondent.)

THE ULSTER MEDICAL SOCIETY.

A VERY interesting meeting in connexion with the Ulster Medical Society took place on June 2nd, on the occasion of the presentation to the Society of the portraits of its former presidents. The invitations sent out by the President and Council were restricted to the medical gentlemen of Belfast and neighbourhood, and between fifty and sixty members of the profession were present in the large room of the Museum, College-square North. The portraits, which are carbonated enlargements of photographs, are admirable likenesses, and bear the autographs of the various presidents. The President of the Society (Mr. John Fagan, F.R.C.S.), who occupied the chair, after bidding all those present a hearty welcome, said they had come together to take part in the pleasing ceremony of the presentation to the Society of the portraits of its former presidents. He said it was not his intention to do more than very briefly introduce the main feature of the evening—viz., the uncovering of the portraits, accompanied by a short notice of the salient points of interest in the lives of each president by the worthy treasurer of the Society, Dr. Esler, to whom the entire credit of initiating this project was due, and who by his unflagging zeal and energy had brought it to its present successful completion. Dr. Esler (whose admirable "Guide to Belfast" was so much valued at the time of the meeting of the British Medical Association) said that in a previous paper he had given some account of the progress of medical matters in Belfast during a period of two centuries; that paper concluded with a hope that on a future occasion he should be enabled to ask this Society to accept the custody of the portraits of its former presidents. It was for this object, he said, they were now met. Dr. Esler then gave an interesting account of the various presidents, their portraits being uncovered as he proceeded. These pictures having been handed over to the custody of the President, who expressed pleasure in receiving them on behalf of the Society, a hearty vote of thanks was passed to Dr. Esler, and those present adjourned to an adjoining room for supper.

THE LUNATIC ASYLUM.

Through the death of Dr. Mac Cormac, who was Visiting Physician to the Asylum, a valuable appointment has became vacant, and a vigorous canvass is being made by a number of medical men who are candidates for the post. The governors make the appointment.

THE CORONERSHIP OF SOUTH ANTRIM.

Dr. Adams (Ashville) has been elected coroner for South Antrim. There were originally five candidates, all members of the medical profession, but eventually only two went to the poll, the others having retired. These were Dr. Adams and Dr. Spearing, the former being elected by a large majority.

Belfast, June 14th.

PARIS.

(From our own Correspondent.)

DR. JAVAL ON GLAUCOMA.

DR. JAVAL, the well-known ophthalmologist and director of the Ophthalmological Laboratory of the Sorbonne, recently delivered a very interesting lecture on Glaucoma, which he considers to be one of the most difficult subjects in ophthalmology. The lecturer chose this subject to demonstrate the fallacies that prevail even among specialists concerning the etiology and pathology of this affection. He remarked that the premonitory signs and symptoms are of little or no value as a means of diagnosis, as the same may be found in other affections of the eye. Even the ophthalmoscope does not render much assistance, as the excavation of the optic nerve is only produced at a later stage, and the pulsation of the central artery of the retina may be missing in glaucoma, and it has been seen in healthy eyes. And yet it is of importance that glaucoma should be early recognised and properly treated, as any error in diagnosis or treatment will inevitably lead to the most disastrous results. It is now known that expectant treatment is not permitted in glaucoma, and it is also known that the instillation of a single drop of atropine might produce irremediable mischief in an eye affected with glaucomatous prodroma. Even cocaine, notwithstanding the diminution of the compression which habitually follows its employment, might produce, in glaucomatous eyes, effects as baneful as those produced by atropine. When an eye feels hard to the touch and is accompanied with perikeratic injection, an immobile pupil and a rough and painful cornea, the diagnosis is easy enough; but it must be remembered that, in general, glaucoma sets in by alterations so fugitive that no ophthalmoscopic sign reveals its existence. If, however, a patient complains of weakness of vision, and the surgeon observes the least inequality of the pupils, or the least paresis of the sphincter of the iris, Dr. Javal cautions against the instillation of atropine or cocaine, adding that an eye affected with glaucomatous prodroma is not always hard and may not present any abnormal appearance. The halo, however, observed by the patient is a sign by which a glaucoma may be known at its onset; but, as other affections may produce these halos, Dr. Javal recommends the instillation of eserine, and if the halos disappear under its influence the diagnosis is no more doubtful. As regards the treatment of glaucoma, Dr. Javal states that the same eserine will serve to combat the accidents of the commencement of the malady, and recommends it to be used in the form of gelatine tablets, instead of collyria, as being more convenient than the latter. If, after the application for a few days of the eserine the symptoms are not completely arrested, surgical interference becomes absolutely necessary. But should an oculist not be within reach, and as every moment of delay is of importance, any medical man might afford temporary relief by making a slight incision of a few millimetres into the globe of the eye near its equator, between the internal recti and inferior recti muscles, as recommended by M. Parinaud. This little operation will permit the patient to proceed to an oculist, who ought to perform iridectomy without delay, and set aside sclerotomy, which is a useless and dangerous operation in such cases.

Dr. Pozzi, agrégé of the Paris Faculty of Medicine and hospital surgeon, is charged with a mission to Germany and Austria to examine the programme and arrangements for the study of gynæcology in those countries.

Paris, June 15th.

POLLUTION OF THE RIVER LEA.—At the last meeting of the Select Committee appointed by the House of Commons to inquire into the pollution of the Lea, after Mr. Armstrong Smith, C.E., had given evidence, Dr. Meymott Tidy explained the results of various examinations of the River Lea which he had made since 1882. He was perfectly certain that the Hertford sewage did not pollute the river. He had made between 5000 and 6000 analyses of the water supplied by the East London Company, and he could say without hesitation that that water was improving year by year.

METROPOLITAN HOSPITAL SUNDAY FUND.

A LARGE and influential meeting was held on Thursday afternoon at the Mansion House, under the presidency of the Right Hon. the Lord Mayor, to inaugurate the series of meetings to be held next week in various parts of the metropolis in support of the Hospital Sunday Fund. His Lordship was supported by the Duke of Norfolk, Cardinal Manning, Capt. Palliser, the Rev. Dr. Rigg, Mr. Brudenell Carter, Mr. Henry C. Burdett, and other friends of the movement. The Lord Mayor having briefly opened the proceedings, Cardinal Manning moved a resolution calling for a greater feeling of sympathy and co-operation in support of the hospitals and medical charities of the metropolis. The resolution was seconded by Mr. Burdett, and agreed to. Mr. Brudenell Carter, F.R.C.S., President of the Medical Society of London, having delivered an address on the importance not only to the poor, but also to the wealthy, of the efficient maintenance of hospitals, it was resolved, on the motion of the Rev. Dr. Rigg, seconded by Capt. Palliser, that a cordial vote of thanks be accorded to Dr. Wakley, the Editor of THE LANCET, who had started this movement of the Hospitals Week, and, at the same time, promised a further contribution of £1000, on condition that four other similar contributions were promised before July 1st. A vote of thanks to the Lord Mayor, proposed by the Duke of Norfolk, brought the proceedings to a close. A fuller report of this meeting will appear in our next issue.

Obituary.

WILLIAM WHITE COOPER, F.R.C.S., F.R.S.

WILLIAM WHITE COOPER was descended from an old Wiltshire family. He was born at Holt, in Wiltshire, on Nov. 17th, 1816. His grandfather was rector of Hambledon, in Surrey, and vicar of Yelminster. White Cooper came to London about 1834, and entered as a student at St. Bartholomew's Hospital. He also became a private pupil of the late Mr. Stanley, surgeon to that hospital, and used to relate that he paid £1000 for that privilege. He became a Member of the College of Surgeons in December, 1838, and a Fellow by examination in 1845. After leaving St. Bartholomew's Hospital he took a voyage to Madeira, and on his return published a Guide for future visitors seeking a winter home in that island. A year or two was then passed in travel, and then he settled in London. He did not intend originally to practise as an ophthalmic surgeon, but, becoming associated with the late Mr. Dalrymple, he decided to devote himself entirely to ophthalmic practice. While at St. Bartholomew's Hospital he gained the only prize Sir Richard Owen gave for Comparative Anatomy. Sir Richard writes to us that "Cooper, then a student, gained my prize for his diligent attendance and the fulness and accuracy of his notes. These, after revision, I consented to his publishing, and they appeared in successive numbers, making an eighth volume, on the 'Anatomy and Physiology of the Invertebrate Animals,' issued by Longmans in 1843." It was this early introduction to Richard Owen that led subsequently to a friendship which was only terminated by death, for Sir Richard writes of Cooper as his "dear and deeply regretted friend."

White Cooper was selected by the late Sir James Clark (we believe at the recommendation of Sir Benjamin Brodie) for the post of surgeon-oculist to the Queen in 1859. He was one of the original staff and senior surgeon of the North London Eye Institution in Charlotte-street, Portland-place, and was connected with it until appointed ophthalmic surgeon to St. Mary's Hospital. He was a careful, steady, and neat operator, and judicious and painstaking in all that related to treatment. He had great facility in illustrating with his brush any cases of interest of which he wished to keep a record. Brought up in the school of Tyrrell and Dalrymple, he was content rather to rest on the principles of their teaching and practice than follow the more modern improvements and treatment which have done so much for ophthalmic practice; but he was ever generous and ready to yield to the opinions of his juniors when satisfied of the advantages to be gained by their adoption. White Cooper published his "Practical Remarks on Near Sight, Aged Sight, and Impaired Vision" in 1847, and in 1850 "Observations on Conical Cornea"; also a small work "On Wounds and Injuries of the Eye" in 1859.

The subject of this memoir had long been ailing. In the autumn of 1884 he suffered from blocked veins of the left leg, associated with a general gouty condition. He was advised to leave London for his residence in the country, and there, within a few days of his arrival, the chronic inflammatory state of the veins assumed a more serious character. The veins of the thigh became acutely implicated, and considerable œdema of the whole limb was the immediate result. He now suffered much from constitutional disturbance. Not long after this, and apparently dependent on some exertion in movement, the right limb became suddenly implicated, and for some days his condition appeared somewhat critical. Under the judicious care of his old friend, Mr. Buée, of Slough, he gradually recovered, and was able to return to work in town in the early summer of 1885. Still, it was apparent to those who watched him that he was not in a condition for much work, and so continued during the autumn and winter, content with the slow improvement which enabled him to receive patients at his house. He had made much progress in health and strength when, unfortunately, like many others during this last fatal spring, he became suddenly the subject of an acute attack of pneumonia. Late on the Saturday night, the 29th ult., he was first seen by Dr. Wilson Fox, and on the following day by Sir William Jenner in consultation. But, notwithstanding their constant attention, he succumbed on the following Tuesday. From the commencement of the attack there did not appear to be any rallying power. The announcement of his death came as a shock to many who had seen him in apparent good health but a few days previously, while those who knew what he had undergone in his previous illness were not taken by surprise at the severity of the attack, or at the rapidly fatal result which so soon terminated his sufferings. He had long been failing, and the system so sapped was ready to yield to any urgent call upon its resources.

Of the private character of White Cooper, all that can be said in his favour would be accepted as truth by those who knew him, and who alone would appreciate his worth. Kindness, gentleness, and true sincerity, combined with a certain simplicity of character; much energy, without the least approach to ostentation or display,—these were the leading traits of his character and conduct. A former colleague writes of him: "How true a friend he was, how kind, yet how unostentatious, memory bears witness. I met him a few times in consultation in practice, and saw in him always the courteous English gentleman and the trusted adviser." In his professional work the deceased gentleman was for many years fully occupied; while he was the trusted adviser of Her Majesty the Queen in all matters connected with his department of practice. It was after many years of faithful service—service fully appreciated and publicly acknowledged—that Her Majesty graciously intimated her intention of conferring a knighthood upon him. The very same day that poor White Cooper's name appeared in the public papers as participating with others in the intended honour, he was seized by his fatal illness. Nor did he live to have the knighthood conferred upon him. He died on the 1st of June. On the 2nd there appeared in the *Court Circular* the following touching allusion to his death: "The Queen has received this morning, with great regret, the news of the death of Mr. White Cooper, who attended Her Majesty for upwards of thirty years as oculist, and for whom Her Majesty had a sincere regard." When White Cooper was confined to his bed at his country residence, near Slough, the Queen drove over from Windsor to see him, and condescended to pay him a visit in his room, such was her regard for him, and such the interest Her Majesty evinced in his recovery and welfare. The public are familiar with the many acts of kindness and sympathy shown by the Queen to those whom Her Majesty knows and esteems, when sorrow and sickness visit their homes; but it is almost exceptional that the trusted medical advisers of Royalty have been ever visited by their Sovereign in the sick chamber. It is, therefore, with great pleasure that we record this pleasing act of courtesy and sympathy on the part of Her Majesty to a member of our profession. White

Cooper married, in 1845, the eldest daughter of Samuel Poyser, Esq., of Derby, who survives him. His eldest son is at present resident house-physician at St. George's Hospital. White Cooper was connected by marriage with the families of Sir Benjamin Brodie and the late Sir George Staunton.

H. ROYES BELL, F.R.C.S.

A GREAT shock was sustained by the medical staff and pupils of King's College Hospital when it was announced that this estimable gentleman and excellent surgeon had been suddenly called away in the prime of life and in the midst of usefulness. Born in Australia, he was brought over to Jersey, where his general education was commenced, and was subsequently completed at King's College. He entered the medical department in 1859, and was attached as a private pupil to Mr. Henry Smith, at that period surgeon to the Westminster General Dispensary, and diligently attended the practice of that institution until Mr. Smith was appointed assistant-surgeon to King's College Hospital. Mr. Royes Bell was conspicuous for his devotion to his studies, and, directing his attention more especially to surgery, was elected house-surgeon to the hospital. Having completed his tenure of this office, he paid a lengthened visit to the hospitals of Paris and Vienna. Returning to London, he was appointed surgical registrar to his old hospital. Having passed the fellowship of the College of Surgeons, he was appointed assistant-surgeon to the hospital in 1870, and having served the usual period in that capacity, was made full surgeon, and subsequently demonstrator of practical surgery. Sir William Fergusson was especially attracted by Mr. Bell's devotion to his work, and for some years before his death employed him largely in his private practice, and Mr. Bell repaid the confidence thus shown by always entertaining and expressing the utmost reverence for his old teacher, admiring him not only for his brilliant qualities as an operator, but for that consummate skill in the detection of surgical disease which, to those who knew Sir W. Fergusson well, was, after all, the main element in his character.

During the many years that Mr. Bell was attached to King's College Hospital he signalised himself by a thorough devotion to his work and to the training of those placed under his charge, with the result of gaining the esteem and affection of all who came in contact with him, and it may be with truth averred that no one connected with the place was more popular in the true sense of the word. The secret of his great influence and of the love he inspired lay in the fact of his utter unselfishness and his thorough consideration for others, combined with a sweetness of disposition which was evinced in his daily intercourse with all around him, and which gave such a bright colouring to his life. Retiring and modest in manner, and constitutionally not strong, he never pushed himself forward or made himself prominent in anything but doing good and performing his duty. He was an admirable teacher in the out-patient room, in the wards of the hospital, and in the demonstration room, and it was a great delight to him to feel that his pupils appreciated his efforts to further their interests. His loss will be severely felt both by them and his colleagues.

As a surgeon, Mr. Bell was thoroughly well informed. He was always a student, neglecting no opportunity of improving himself in the art to which he had devoted his life. Although not endowed with some of the more striking qualities which belong to some surgeons, and somewhat hesitating in manner, he was remarkably painstaking, and the results of his operations, especially in cases of hare-lip, cleft palate, and plastic surgery, were excellent. His main contribution to surgery consisted of the Lettsomian Lectures on Diseases of the Testis, and he was chosen as one of the contributors on the same subject to Ashhurst's Encyclopædia.

JAMES C. L. CARSON, M.D.

THE death of this well-known and much-respected practitioner took place on Wednesday, June 2nd, at his son's residence, Coleraine, where for some time he had been in failing health. Dr. Carson, who at the time of his death was in his seventy-first year, was the son of the Rev. Dr. Alex. Carson, Tobermon, county Derry. He entered Trinity College, Dublin in 1833, and subsequently attended a course of lectures at the Glasgow University, where he graduated M.D. in 1837. When very young he commenced practice in Ballymena; but his brother, Dr. George Carson, who was then practising in Coleraine, having died, he removed to that place to succeed him, and in 1851 he again went to Dublin, where his health gave way. Next year he returned to Coleraine, where he continued as the leading practitioner in that district until a few years ago, when he was obliged to retire owing to failing health. Dr. Carson was a man who wrote on a variety of subjects; he published a treatise on "The Form of the Horse"; a work on "Capital Punishment," in which he advocated the abolition of the punishment of death; and an interesting *brochure* on the "Fundamental Principles of Phrenology." He also contributed papers on controversial religious subjects. In 1875 he was made a Justice of the Peace. Dr. Carson, who in his life had many medical appointments in Coleraine, was a man held in the highest respect by the general public, who had full confidence in his skill, tact, and attention.

WILLIAM SOUTHALL, F.L.S.

A DISTINGUISHED botanist and pharmaceutist of the type of the late Daniel Hanbury, F.R.S., and like him a member of the Society of Friends, has just passed away, aged sixty-one, at Edgbaston, near Birmingham. William Southall was for twenty-one years one of the examiners of the Pharmaceutical Society, and was chosen President of the British Pharmaceutical Conference in 1879. He was also a Fellow of the Linnæan Society, and one of the founders of the Birmingham Natural History and Microscopical Society. One who knew both well bears strong testimony to the close resemblance in manner and person of the late Mr. William Southall to the lamented Mr. Joseph T. Clover. Both were most kindly men, full of love and knowledge of their respective professions, and deeply yet unobtrusively religious. Strangely enough, both succumbed to the same pulmonary complaint, after having suffered from it for many years.

MEDICAL NOTES IN PARLIAMENT.

Burgh Police and Health (Scotland) Bill.

IN the House of Commons, on the 11th inst., the order relating to this Bill was read and discharged and the Bill withdrawn.

The Lunacy Acts Amendment Bill.

The order of the day for the second reading of this Bill was read and discharged.

The Medical Acts Amendment Bill.

This Bill was read a third time.

The Sanitary State of the House.

In reply to a question by Mr. R. Cooke, Mr. Leveson-Gower stated that orders have been given for the carrying out of those recommendations of the Committee on the Ventilation of the House, which it was possible to undertake immediately. These works cannot of course be completed, as had been intended, during the Whitsuntide recess, but they can be carried on when the House is not actually sitting, and will be finished without delay. The First Commissioner has requested Mr. Shone, the inventor of the system recommended by the Committee, to furnish him with a report on the question of costs, and as to how the system, if adopted, could be most speedily and effectually brought into operation.

Contagious Diseases (Animals) Bill.

On the 16th inst. this Bill was read a second time.

METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.—On the 9th instant, a meeting of this Association took place at the residence of Mr. Hollond, 1, Upper Berkeley-street, Portman-square. Of the eleven dispensaries, five are now entirely self-supporting. The sum of £500 is required to meet the requirements of those not yet self-supporting. The subscription is 6*d.* a month for single persons, 10*d.* a month for married people, and 6*d.* for a family of children. The Dean of Westminster and Sir Spencer Wells spoke in support of the institution.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members, having passed the Final Examination for the Fellowship on the 26th, 27th, 28th, and 29th ult., were, at a meeting of the Council on the 10th inst., admitted Fellows of the College:—

Trott, Dudley Cox, L.R.C.P.L., Longton-grove, Sydenham; Membership dated Nov. 17th, 1880.
Sinclair, T., M.D.Q.U.I., Howard-street, Belfast; April 18th, 1882.
Buckell, William R., L.R.C.P.L., Romsey; May 16th, 1882.
Horrocks, William Henry, L.S.A., Shoreham, near Liverpool; Nov. 14th, 1882.
Thorburn, Wm., M.D. Lond., Rusholme, Manchester; July 24th, 1883.
Blaxland, Walter, L.R.C.P.L., Torrington-square; Nov. 13th, 1883.
Bowes, William Henry, M.D. Lond., Marine-terrace, Herne Bay; April 24th, 1884.
Heath, Charles Joseph, L.S.A., Guilford-street; July 31st, 1884.
Pearson, Charles Yelverton, M.D.Q.U.I., King-street, Cork.

Four other candidates passed the examination, but not having attained the legal age (twenty-five) will receive their diplomas at a future meeting of the Council when qualified. Fourteen candidates failed to reach the required standard, and were referred to their professional studies for one year.

UNIVETSITY OF CAMBRIDGE.—At a congregation held on the 10th inst. in the Senate House, Dr. Swainson, Vice-Chancellor, presiding, the following degrees were conferred:—

M.D.—W. R. Parker, Caius; W. L. Penney, Caius; F. W. Hewitt, Christ's.
M.B.—E. C. Perry, King's; C. W. Daniels, Trinity; C. Yeoman, Pembroke; W. H. Smart, Caius; A. C. Ingle, non-coll.
B.C.—C. Yeoman, Pembroke; A. C. Ingle, non-coll.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 10th inst.:—

Elliot, William Henry Wilson, Bremar-road, Denmark-hill.
Hallilay, Richard Percy, Burley-road, Leeds.
Hardwick, Arthur, Victoria Villas, Dorchester.
Rawnsley, Gerald Thomas, Royal Dockyard, Woolwich.

THE Hospital Sunday collection at Ripon was held on the 13th inst.

DR. ALEXANDER HARKIN, J.P., has been appointed to the Commission of the Peace for the county of Antrim.

THE Court of Common Council has voted £105 to the Hospital Sunday Fund.

BRITISH MEDICAL BENEVOLENT FUND JUBILEE CELEBRATION.—Her Majesty the Queen has, through Sir James Paget, sent a donation of £100 to this fund.

VACCINATION GRANT.—Mr. Henry Wickham, of Rufford, Ormskirk, has received the Government grant for efficient vaccination (second time).

AT a public meeting held on the 11th inst. at the Holborn Town Hall, it was decided to establish a Convalescent Home for the poorer classes at the Vale of Health, Hampstead.

PLEURO-PNEUMONIA appears to be prevalent amongst cattle in different parts of the country—to wit, Surrey and Dorsetshire. Slaughtering and inoculation are being resorted to, the latter seemingly with some success.

A SPECIAL meeting of the governors of the Bristol General Hospital was held on the 9th inst., for the purpose of considering a revision of the rules of the institution, which is to be brought forward at a forthcoming general meeting of the subscribers.

EPIDEMIC IN AN EGYPTIAN PRISON.—In a convict prison at Tantah, containing 1100 inmates, 200 prisoners have died within the last six weeks from an obscure epidemic. Dr. Green, principal medical officer of the Sanitary Department, has accordingly demanded an inquiry into the management of the prisons, and a commission, consisting of a colonel and three army surgeons, has been nominated for the investigation.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination, held on June 3rd and 4th, 60 candidates presented themselves, 10 as local surveyors, of whom 5 obtained certificates of competency, and 50 as inspectors of nuisances, of whom 44 were successful.

AT an inquest held on the 11th inst. on the body of Mr. R. Drury Batt, late assistant medical officer at a private asylum at Barnwood near Gloucester, whose death had been caused by prussic acid, the jury returned a verdict of suicide while in an unsound state of mind.

SCARLET FEVER HOME.—The first annual meeting of the Mary Wardell Convalescent Home for Scarlet Fever, Stanmore, will be held to-day (Friday, June 18th), at 5 P.M., at 32, Sackville-street, Piccadilly. Sir Risdon Bennett, M.D., F.R.S., will preside.

SOCIETY OF MEDICAL MEN QUALIFIED IN SANITARY SCIENCE.—Professor R. Koch, M.D., of Berlin, has accepted the honorary membership of this Society. This Society, which has been but two months and a half in existence, already embraces 100 members who possess sanitary qualifications.

A UNIQUE COLLECTION.—A curious sale of skeletons is said to be about to take place in Paris. The collection belonged to a French doctor who devoted his existence to studying distorted human nature, and visited the hospitals to buy up the corpses of deformed persons. By this means he formed a unique museum of abnormal skeletons, for which his heirs now ask £1200.

DEATHS OF FOREIGN MEDICAL MEN.—The death is announced in Dresden of Eugen Burckhardt, editor of the *Correspondenzblatt der ärztlichen Kreis- und Bezirksvereine im Königreich Sachsen*.—Dr. Ingels, the well-known alienist, died at Ghent on the 22nd ult.—The death is announced of Dr. Don Joaquin Chillida y Meliá, late editor of the *Revista Médico Farmacéutica*, of Castellon, and author of an important Spanish work on the Hygiene of Schools.—Dr. Robert Falkson, privat docent in Surgery in Königsberg, has died at the age of thirty-one.

GIFTS AND BEQUESTS.—The Committee of the Southport Infirmary and Local Dispensary have recently received a cheque for £500 from Miss Cooper of Southport towards the endowment fund of the children's ward.—By the death of Mrs. Surtees of Harrogate the following legacies, amongst others, become payable:—Harrogate Cottage Hospital, £200; Royal Infirmary, Edinburgh, £200; Sunderland General Infirmary, £250; Sunderland Children's Hospital, £50.—Mrs. Booth, of Beechfield, Swinton, has given a donation of £500 to the Manchester Clinical Hospital for Women and Children.

FOREIGN APPOINTMENTS.—Don Manuel Alonso Sañudo has been nominated to the chair of Medical Pathology in the Faculty of Medicine of Valladolid. Don Enrique Gelabert, editor of *La Higiene para Todos*, has been appointed Sanitary Officer for the Port of Barcelona. Don Eduardo Luis, inspecting surgeon of the second grade, has been appointed President, and Surgeon-Major Don Ramo Alba y Lopez Secretary, of the Examining Committee for the selection of candidates for the Medical Service of the Spanish army. In Prague Dr. Huppert has been appointed to lecture on Chemistry this semester, in place of Dr. Linnemann, the recently deceased professor of that subject. Prof. Götte of Rostock has been appointed to the chair of Zoology in Strasburg, in succession to Prof. Oscar Schmidt.

DARENTH IMBECILE ASYLUM AND SCHOOLS.—On the 12th inst., the managers of the Metropolitan Asylums Board paid their annual visit to this institution, which is situated some three miles from Dartford. The estate, exclusive of land recently acquired for the purposes of a hospital for convalescent small-pox patients, comprises 173 acres, and of this about 130 acres are under cultivation. The buildings are erected upon the block principle, and at the adult asylum accommodation is at present provided for 800 harmless insane patients. This accommodation, however, has been found to be too small to meet the growing requirements, and it will shortly be increased by 550 beds. The schools for imbecile children contain certified accommodation for 500 children. The result of the inspection is reported to be satisfactory.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ALLOTT, J. H. L., M.B., C.M.Ed., has been appointed Resident Assistant Medical Officer to the Crumpsall Workhouse of the Township of Manchester.

BROWNE, OSWALD, M.A., M.B.Cantab., M.R.C.P., has been appointed Casualty Physician to St. Bartholomew's Hospital.

CLAY, AUGUSTUS F., M.R.C.S., L.S.A., has been appointed Assistant Surgeon to the Birmingham and Midland Counties' Orthopædic Hospital.

CLIBBORN, WILLIAM, M.D.Dub., L.R.C.S.I., has been appointed District Medical Officer and Medical Officer to the Workhouse of the Bridport Union.

DAVIES, ARTHUR T., B.A., M.B.Cantab., M.R.C.P., has been appointed Assistant Physician to the Royal Hospital for Diseases of the Chest.

FLETCHER, RORY, M.R.C.S., has been appointed House-Surgeon to Charing-cross Hospital.

GRENFELL, H. O., M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to Charing-cross Hospital.

HABERSHON, S. HERBERT, M.A., M.B.Cantab., M.R.C.P., M.R.C.S., has been appointed Assistant Physician to the Royal Hospital for Diseases of the Chest.

HARDY, ALBERT E., M.R.C.S., L.S.A., has been appointed House-Physician to Charing-cross Hospital.

HODGSON, T. MOORE, M.B., C.M.Ed., has been appointed Assistant House-Surgeon to the Cumberland Infirmary, vice G. H. Henderson, M.R.C.S., resigned.

LEES, W., M.R.C.S., L.S.A. (late Visiting Surgeon to the Chester General Infirmary), has been appointed House-Surgeon to that Institution.

LIDDERDALE, JAMES, M.R.C.S., L.S.A., has been appointed Medical Officer for the Seventh District of the Bedminster Union.

MACKENZIE, A. L., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the First District of the Romford Union.

MORRIS, PRYCE J. L., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer of Health for the Blything Union, vice A. B. Deck, deceased.

NOYES, A. W. FINCH, M.R.C.S., L.R.C.P.Lond., has been appointed House-Physician to Charing-cross Hospital.

OLIVER, F. H., L.S.A., has been appointed Resident Obstetrical Officer to Charing-cross Hospital.

PRINCE, HERBERT F., L.F.P.S.Glas., L.S.A., has been appointed Medical Officer for the Great Bedwyn District of the Hungerford Union.

STURROCK, W., M.B., C.M.Ed., has been appointed Assistant Medical Officer to the Workhouse of the Parish of St. Pancras.

TURNER, ARTHUR F., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Deerhurst District of the Tewkesbury Union.

WETHERED, FRANK J., M.R.C.S., L.S.A., has been appointed Assistant House-Physician to the Royal Hospital for Diseases of the Chest.

WILLIAMS, ROBERT R., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Workhouse and Infirmary of the Parish of St. Leonard, Shoreditch.

Births, Marriages, and Deaths.

BIRTHS.

BURGESS.—On the 12th inst., at Nicoll-road, Harlesden, the wife of W. Milner Burgess, M.R.C.S.E., of a daughter.

CHANING-PEARCE.—On the 9th inst., at Montague House, St. Lawrence-on-Sea, Kent, the wife of J. Chaning-Pearce, M.D., of a son and daughter.

SLAUGHTER.—On the 13th inst., at Dover, the wife of W. B. Slaughter, Surgeon-Major, Medical Staff, of a son.

WALLIS.—On the 16th inst., at Woolwich-common, the wife of Charles Wallis, M.R.C.S., of a son.

MARRIAGES.

BERRY—CURRIE.—On the 9th inst., at St. Alphege, Greenwich, Harry Poole Berry, M.B.Lond., M.R.C.S., of Grantham, to Rosina Jessie, eldest daughter of Alexander Currie, of Leslee, Westcombe-park, Blackheath.

MOSSE—HAMMERTON.—On the 10th inst., at St. Andrew's, Stockwell, Herbert Ryding Mosse, M.D., M.R.C.S., of Hobart House, Clapham-common, to Katharine, youngest daughter of C. Hammerton, Esq., of Stockwell, S.W.

WALLACE—MORDACQUE.—On the 10th inst., at the Parish Church of St. Peter's Port, Guernsey, Alfred Cyprian Wallace, L.R.C.P.Lond., M.R.C.S., to Theodora, youngest daughter of the late Rev. L. H. Mordacque, M.A., J.P., Vicar of Haslington, Lancashire.

DEATHS.

BELL.—On the 15th inst. (suddenly), Hutchinson Royes Bell, F.R.C.S., Honorary Fellow of King's College, and Surgeon to King's College Hospital, of 12, Queen Anne-street, Cavendish-square, aged 44.

POWER.—On the 9th inst., at 65, Ashburnham-road, Bedford (suddenly), of syncope, John Arthur Power, M.A., and L.M.Cantab., L.R.C.P.Lond., late Senior Fellow of Clare College, Cambridge, aged 76.

YULE.—On the 8th inst., at Fern Lea, Worthing, John Strelley Carslake Yule, M.R.C.S., aged 47.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE TURKISH BATH.

Dr. Grant writes calling attention to a want in connexion with the various Turkish baths in London, which, judging from his own case, deters many persons from more frequently making use of them—viz., the absence of any hotel or of bedrooms under the same roof as the bath. Apart from the time taken in undressing and dressing, it is evident that the unavoidable exposure to weather and the fatigue involved in proceeding to the bathing establishment are injurious in many cases for which the Turkish bath is recommended, and in which it is beneficial. Our correspondent states that he has on several occasions thought it worth his while to proceed to Dublin, where there is an hotel in connexion with the baths, and where they can be taken in a comfortable manner, and expresses the opinion that the establishment of such conveniences in the West-end of London would prove profitable to the proprietors.

Dr. Fraser (Ashburton).—1. The best account will be found in the last edition of Waring's Handbook of Therapeutics.—2. We have no information respecting the publication to which our correspondent refers.

Students.—All the information will be found in our Students' Number, published in September last.

Graduate.—We doubt very much whether it would be possible.

"ALCOHOL IN HOSPITALS."

To the Editor of THE LANCET.

SIR,—In your last issue a paragraph entitled "Alcohol in Hospitals" concludes with the following words: "The Secretary of the Middlesex Hospital has calculated that 66 per cent. of the expenditure on alcohol is for its consumption by officials." This passage having been commented upon, will you allow me to observe, in the first place, that I have never made any calculation on the subject in question, and, secondly, that the figure quoted is inaccurate. Possibly the calculator has based his reasoning on data of which I am ignorant; but in 1884 this hospital spent £547 4*s.* 7*d.* on beverages containing alcohol, of which £328 10*s.* 9*d.* was for the amount consumed by patients and £218 13*s.* 10*d.* for that used by the resident officers, the nurses, and the servants. The percentage would therefore be about 60 for patients and 40 for officials. I trust your sense of fairness may allow me space enough in your next issue for the insertion of this correction.

I am, Sir, your obedient servant,

A. O'D. BARTHOLEYNS,
Secretary.

Middlesex Hospital, June 17th, 1886.

TONSILLARY CALCULI.

To the Editor of THE LANCET.

SIR,—So rare is this affection, and so unusual the occurrence of two fairly large calculi being deposited in one tonsil, that it may be deemed of sufficient interest to be placed before your readers.

Recently Mrs. C—— consulted me with reference to an inflamed throat, with some slight difficulty in swallowing, and which had existed, more or less, for some months. The patient had occasionally sought advice, but had obtained only temporary relief. The mouth could be freely opened, and the tonsils well exposed by depressing the tongue and drawing back the cheeks by an elastic retractor. The right tonsil was seen projecting conically inwards behind the uvula, having a yellow speck on its apex. To the touch this was hard, and grated under the probe. While thus exploring it a violent spasmodic effort, partly coughing and partly vomiting, came on, forcibly expelling a calculus the size of a large horse-bean, the relief being immediate. However, a few days later the patient called again, saying there was another calculus. The tonsil looked red and felt hard. On passing a probe into the sulcus left by the previous calculus I came upon something hard. Slitting up the tonsil and manipulating with a bent probe and blunt hook, I was enabled after some little difficulty to extricate another calculus, larger than the previous one, round, but very nodular, and in appearance very much like a vesical mulberry calculus. It weighed nearly a drachm, and its composition was chiefly phosphatic.

The peculiarities of this case appear to be its rarity and the existence of two large bodies in one tonsil causing so little inconvenience in a part ordinarily so sensitive. Though some authorities look upon calculi as the resolution of some tuberculous deposits, in this case all physical and constitutional symptoms were perfectly healthy, while the family history was exceptionally good; nor could I trace that the patient had suffered from follicular catarrh, thereby causing vitiation of the ordinary tonsillar secretion. The only solution I can give is that the crypts or follicles were unusually patent, allowing the accumulation of the buccal or salivary mucus, from which a gradual deposit was thrown down, while the treatment could be no other than that followed by me.

I am, Sir, yours faithfully,

Leamington, June 15th, 1886. CHARLES MARRIOTT, M.D.

H. A. M. (Colchester).—Vitruvius, in his treatise on Architecture, written in the reign of the Emperor Augustus, B.C. 10, says (Book I., chapter i.) that the architect should have a knowledge of medicine (*medicinæ non sit ignarus*). Claude Perrault (1613-88), himself a physician, returned the compliment by a careful study of architecture, by an excellent translation of the work of Vitruvius, and by designing the entrance to the Louvre, which in Voltaire's time was pronounced by that connoisseur to be "one of the finest monuments of architecture in the world."

Dr. Milner Fothergill.—Yes.

Q. R. can obtain the information through any of the leading agents.

THERMOMETERS.

To the Editor of THE LANCET.

SIR,—I have read letters in praise of the circular clinical thermometers, and I think that those whose experience has not been so encouraging ought also to give their opinion. I was highly pleased at the thought of having a thermometer which would hook on to the swivel of my watch chain, and consequently would always be at hand, instead of being left behind in another pocket; but I have found it clinically useless. If placed in the mouth, it will certainly register up to 98·5° F. in a healthy subject; but it is not the sort of instrument to be passed from mouth to mouth, as a glass one may be. In the axilla, to whatever point it may reach, I have never secured a reading much above 90°, owing to the rapidity with which it runs down while the patient is fumbling for it, and while one is turning it round to the light. A friend has suggested to me that a ratchet arrangement might be contrived on the face of the dial, which would catch the pointer at each successive degree which it reached, and that the pointer could afterwards be released by pressing a spring.

I am, Sir, yours truly,

June 15th, 1886. M.D. DURH.

Dr. B. Walter Jones (Vulcan, Mich., U.S.A.).—The name was given in the description of the apparatus.

Mr. C. G. Jones.—The usual minimum fee paid by high-class offices is £1 1*s*.

A CAUTION.

To the Editor of THE LANCET.

SIR,—The following description of a thief who on Saturday morning last made a successful raid on my consulting-room by means of the usual request to be allowed to "wait a few minutes" may be of service in putting your readers on their guard, and might possibly lead to his apprehension:—He is a short man, about forty, with "sandy" hair and beard, dark brown eyes, and sunburnt complexion; he wears a blue serge suit, also a ring and a watch, which he takes care to show as evidence of respectability.

I am, Sir, your obedient servant,

June 15th, 1886. W. G. D.

O. O. O.—Our correspondent is not called on to disclose professional secrets, save in a court of law.

THE SPANISH MEDICAL PRESS.

IN Spain almost every town containing a medical faculty, of which there are some eleven, boasts several small weekly or monthly medical journals. A new candidate for professional favour is now announced from Barcelona, *La Vara de Esculapio* (*The Staff of Æsculapius*), which makes, if we are not mistaken, the third new medical journal emanating from the same provincial city which has come into existence during the last few months, there being nearly a dozen already published there.

G. H. W.—Dr. William Farr pointed out more than forty years ago the fallacy underlying any attempt to base conclusions as to the health condition of populations upon the observed "mean age at death" occurring therein.

T. L.—We have no knowledge of the institution named.

THE "PENDJEH SORE."

To the Editor of THE LANCET.

SIR,—With reference to the letter from Mr. Pierson of the Indian Medical Service in your last issue (p. 1148), and to previous communications regarding the "Pendjeh Sore," allow me to state that the disease is well known in Asiatic Turkey, from the Mediterranean to the Persian Gulf; but it is in the Baghdad district that it is most prevalent and most virulent. It is there known as "Nishan-al-Tamar," or date-mark, from the fact that it generally appears in autumn, when the dates are ripe. It is not a constitutional disease, and I have no doubt that Mr. Pierson's theory as to its nature is correct. His remark about the copper-colour of the cicatrices of these sores reminds me of an officer who suffered from them in Baghdad, and who went to England immediately afterwards. He consulted an eminent surgeon of the day, who delicately hinted at syphilis. This the patient indignantly denied, assuring the surgeon that the complaint was endemic in the country from which he had come; but he was listened to with evident disbelief, and he departed in disgust. The date-mark has been frequently described in the Indian medical journals. I am, Sir, yours truly,

J. M. HYSLOP, M.D.,

Edinburgh, June 14th, 1886. Surgeon-Major.

To the Editor of THE LANCET.

SIR,—I fully agree with Surgeon Pierson, I.M.D., in his letter of the 12th inst., that it would be wrong to give currency to the new title "Pendjeh" to what appears to be the "Mooltan" sore. The disease was doubtless new to the Russian surgeon on his coming for the first time to the habitat of the ailment. Such local titles are inevitable and unobjectionable if they do not obscure the identity of disease. "Peshawur fever," "Feral fever," and other local names of ague, have ceased to do harm in this way. I write, however, more especially in reference to the question of treatment. That of Dr. Suski will certainly be found inefficient. Still, there is a remedy, far short of total destruction by nitric acid, which it is surprising is not better known on the frontier—viz., dressing with diluted tincture of the sesquichloride of iron, on lint under waterproof. This is cleanly and painless, and heals the sore rapidly. These sores in former years caused much invaliding to the hills, and even to Europe. Situated, as they often were, on the face and forehead, they presented a most repulsive appearance. This state of things was promptly modified in Mooltan and the neighbouring stations some years ago by the adoption of the above treatment.

I am, Sir, yours faithfully,

June 15th, 1886. A. G. BARTLEY, M.A., M.D.

Forensic.—1. The latest edition of Taylor's Medical Jurisprudence.—2. Thomas or Barnes.

Mr. T. G. Parrott.—We have not space nor patience to notice the letter.

Aristarchus has not enclosed his card.

"INFANTICIDE BY PERAMBULATORS."

To the Editor of THE LANCET.

SIR,—While on a holiday tour in Holland some years ago, I noticed that the infants in their perambulators were much more silent and much happier in appearance than infants in a similar condition in England. I saw that in all cases the infant was lying with its face to the nurse, and was well protected by the hood at its back. If this proceeding were always the rule in England, the exposure, and consequent "danger of inflammatory disease, pulmonary and cerebral," would be reduced to a minimum, and the child, having always its nurse's face in view, would be less disposed to cry.

I am, Sir, yours faithfully,

June 15th, 1886. H. F. S.

Medicus.—No. Melbourne would certainly not be a suitable place of residence for such a patient. The extreme and sudden changes of temperature, the frequent dust-storms, and the defective drainage, which characterise that Australian town, would not operate favourably on a *poitrinaire*.

Jurisprudence.—Jervis on the Office and Duties of Coroner, fourth edition by Melsheimer, published by Stevens and Son, Chancery-lane

Dr. O'Neill.—The notes would be acceptable.

"THE LANCET"

FIRST SPECIAL SUPPLEMENT,

IN SUPPORT OF THE

METROPOLITAN HOSPITAL SUNDAY FUND.

CONCERNING EVERYBODY.

THE Hospitals Week, commencing on Monday, June 21st, which is the prologue to Hospital Sunday, June 27th, is a movement which concerns and should interest all sorts and conditions of men and women in this vast city of London. From the monarch on the throne to the meanest subject in Her Majesty's Empire, from the peer to the pauper, all have need of, and are dependent in the hour of humanity's sorest trial upon, the efficiency of our hospital system for relief and succour. The recognition of this fact no doubt accounts for the presence of the names of the many illustrious and representative men on the imposing list of speakers who will take part in the meetings to be held in every district of London during the Hospitals Week. The list which will be found on p. 13 of this special supplement of THE LANCET, is eloquent, not only by virtue of the names which it contains but also from the absence of others which might reasonably have been expected to appear upon it. The neutral platform this movement affords to the political leaders, who have here an opportunity of turning aside for a brief interval from the turmoil of politics, will be ascended by the more thoughtful of them with feelings of thankfulness, because they will be able to prove once more by their action that one touch of nature makes the whole world kin. No great popular leader can deliberately allow the people to suspect, much less to believe, that he is unwilling to aid, or callous concerning the provision of adequate means for fully relieving the unavoidable illnesses and accidents to which the masses of his fellow-citizens are liable.

All must agree with Rabelais, that "without health life is not life; it is not living life. Without health life is only a state of languor and an image of death." This thought is brought home with greater force, perhaps, to the poor than to any other class. We cannot but believe that all who consent to aid this great crusade against the common enemy to all our race will certainly not miss their reward at the hands of their grateful countrymen. A movement like this arouses all the best feelings of our nature, and so surely as sickness and suffering are no respecters of persons, so surely will those who at some personal sacrifice devote a portion of their health and strength to secure the provision of abundant relief to their less fortunate and suffering neighbours, be better prepared to face the hour of trial when it is their turn to be struck down by an accident or to be overtaken by illness.

> Ah, what avail the largest gifts of Heaven
> When drooping health and spirits go amiss?
> How tasteless then whatever can be given!
> Health is the vital principle of bliss.

So true is it "he dies every day who lives in a languishing state," that none who think at all seriously of life's responsibilities can turn a deaf ear to an appeal for an adequate supply of funds to keep health's machinery, and all those agencies which may be broadly described as health preservers, in efficiency and order.

If this be so, then the diminution in the volume of support which has characterised the last few years' experience of the managers of the London hospitals would be difficult indeed to account for, except that neglect of duty is usually due rather to want of thought than to want of heart. It is, indeed, this experience of the commonest cause of most indifference and neglect which warrants a hopeful estimate of the results which will probably follow the awakening of the public conscience to the needs of the hospitals as one effect of the proceedings in the Hospitals Week. To secure this much, however, it is essential that everyone should put his shoulder to the wheel. Let everybody, therefore, give a hand to the movement. The orator by his eloquence; the leaders of public opinion and of fashion by their presence on the platform; the public by attending the meetings in large numbers; the press by devoting ample space to reports of the proceedings; those who earn their wealth in the City, but who reside outside its area, by sending a cheque to the Lord Mayor at the Mansion House; and all by making it their business to give, at any rate something, in support of the hospitals through the Hospital Sunday Fund. To those who have wealth, a generous and old supporter of the hospitals, Dr. Wakley, who last year gave a donation of £1000 to the Fund, has offered a challenge, by placing another £1000 in the hands of the Lord Mayor for the Hospital Sunday Fund providing four others send an equal sum before the end of July. It is the privilege, as well as the duty, of all classes to combine to make a long pull, a strong pull, and a pull altogether in aid of the hospitals during the Hospitals Week. Shall it be longer possible to say of us, the inhabitants of the wealthiest city in the world, that we give less in proportion to the hospitals than any other city in the British Empire?

Lavater has said there are but three classes of men: the retrograde, the stationary, and the progressive. Londoners, so far as the hospitals are concerned, putting the most favourable judgment on their actions, belong to the stationary, if they are not already entering the retrograde class. This lamentable position is due, in our belief, chiefly to the entire ignorance of the value and work of hospitals to be met with amongst the great majority of all classes of the people. Their knowledge of the subject is limited to the passing acquaintance which they may have of the outside appearance of the one particular hospital which happens oftenest to confront them in their walks abroad. Will they do us the favour, and themselves the justice, of going with us within the hospital walls? The inner life and work of these noble charities are brought by means of this Supplement within a measurable distance of all, and none need longer be content to survey the hospitals through a long vista.

At any rate, we have done our best in these pages, as the leading men of all classes will do their best at the various meetings throughout the Hospitals Week, and the ministers of all the churches will do theirs on Hospital Sunday, to cause Londoners to awake from their lethargy in this matter, and to prove once more that the people of the first city in the Empire have hearts as warm and purses as open as are to be found anywhere in the whole world. The fact that a man lives in the midst of a population of upwards of four millions does not absolve him from the calls of duty or the claims of humanity, and we are convinced that if the attention of the people can only be aroused, as it ought to be aroused, the £80,000 so urgently needed by the hospitals will be gladly suscribed by the combined contributions of all classes of Londoners.

WITHIN THE HOSPITAL WALLS.

A MATTER-OF-FACT NARRATIVE.

(By a Special Commissioner.)

MOST Londoners are familiar with the outside characteristics of certain spacious three-storeyed buildings, to be found in most of the crowded districts of the metropolis. With but an exception or two, they lay claim to no architectural beauty, and attract attention more generally by their brooding ugliness. Most of them were built at a time when architectural taste had temporarily disappeared from this island; and the addition of wings, outbuildings, and unnatural excrescences, to meet the wishes of modern sanitary science, has invariably robbed them of the little beauty they started with. Then, as often as not, scantiness of funds has prevented the architect from stepping an inch beyond the limits of strict utility. Besides, having started plain or ugly, and maintained the traditions up to modern times, it has not been easy for the governing bodies of the day to seriously improve the outside appearance of their institutions. To add a handsome wing to a blackened and weather-frayed structure is, by the contrast occasioned, to increase rather than to diminish the prevailing dreariness. Moreover, it has always been, and still is, a principle with governors that funds available for architectural decoration are better expended in ministering to the comfort of patients, and curing them inside the building, than in offering up outside fresh victims in the shape of polished granite and carved stonework to that scarifying demon of our metropolitan streets—London soot. The heavy awkwardness of the pile is rendered more oppressive by the usual absence of blind and curtain, to soften the oppressive blackness of the windows. Occasionally the gloominess of the window is even enhanced by the lower panes being frosted, and by the black upper panes gaping open for purposes of ventilation in a chilly, dismal manner. No matter how grim and devoid of features to arrest the fancy the façade may be, the inscription "Supported by Voluntary Contributions" is, nevertheless, religiously kept clean and distinct. But the generality of mankind confine their gaze more to the earth than to heaven; and as in most cases this invocation to subscribe might be above the range of sight, the inscription is commonly repeated on the doors and the palings, accompanied by gaping money-boxes, and sometimes a staring fervent appeal for aid.

TROOPING TO THE HOSPITAL.

Every morning the streets converging upon these buildings are thronged by "the lame, the halt, and the blind." Black being the raiment of respectability among the lower middle classes, and those who gain their livelihood by working at various trades, this colour is the prevailing hue of the "out-patient" pilgrims. Light colours betoken a levity out of place in the waiting-rooms of a general hospital, and are only donned by the foolish and frivolous, or by those unfortunates who "went in" for gay apparel in the hour of health and good pay, and who have no other clothes to come in. These, however, try to conform to decency by bringing their bottles and gallipots in black bags, or by adopting a respectable mournfulness of behaviour. Thus the stranger, finding himself in the vicinity of a great hospital at certain hours of the morning, carries away a general impression of black clothes and white bandages, green bottles protruding from black bags, and crutches, eye-shades, and arms in slings, which is not at all calculated to inspire him with a vigorous appetite for luncheon. Should he travel third class on certain suburban lines, he will find that there are trains in the morning known as "hospital trains," when the larger proportion of the occupants of the third-class carriages are out-patients proceeding to town, who not only create a peculiar out-patient atmosphere of their own in the compartment they may be travelling in, but, being often known to one another, convert the said compartment into a sort of forum for the lugubrious discussion of diseases and the ills incidental to man.

WHAT THE HOSPITAL IS SUPPOSED TO BE LIKE.

Thus, everything tends to favour the popular impression that the hospital is a very dismal institution, hardly better than a prison; and few, we imagine, pay a first visit to one without making up their minds to be affected with a nightmare of sorrow and suffering for days to come. As for taking any interest in the hospital, to say nothing of feelings of pride, what average Englishman is there who considers himself under an obligation to concern himself in the least about it while in good health? Yet, as we shall directly show, a general hospital in our great metropolis is not merely an institution founded by the charitable rich for the suffering poor, and therefore, on purely moral and humanitarian grounds, to be commended, but is vitally associated with the personal well-being of every Londoner, no matter to what grade of society he may belong or how sound may be his health. Without exaggerating the case in any respect, it may be said that there is no individual who is not already indebted to the hospital, although he may have never personally applied for relief; and it will not be difficult in a brief account of life in a typical general hospital to demonstrate to the healthiest and most selfish Londoner the immense benefits conferred on him, as well as upon everybody else, by our metropolitan institutions for the alleviation of the sick.

HOW DYER, THE MECHANIC, CAME TO ENTER THE HOSPITAL.

It is not a twelvemonth ago that a mechanic was admitted into the General Hospital suffering from a punctured eyeball. He had been employed at the Dudgeon Engineering Works on the Thames, and was within one hour of taking his discharge, when, in striking almost a final blow at his last piece of work, a bit of metal flew up and entered the eye. A few months previously the works had passed into the hands of a limited liability company, and whatever kindly feeling had at one time existed between master and man had disappeared under the new *régime*. The business was placed "on an improved footing," which meant a general reorganisation and suppression of certain branches that did not pay, accompanied by a turn out of many of the old hands without any reference to the claims they had on the owners by reason of long and faithful service. Among those discharged was this hard-working mechanic, named Dyer, who had been employed most of his working life in the place, and who was of acknowledged respectability. Sickness in his large family at different times, and troubles occasioned through trying to buy his house from a bogus building society, had brought him down to the level of his actual wages, and he had but a poor prospect before him, when, on being helped to the nearest doctor's, the cashier's clerk put his last pay into his pocket. The man was recommended to go the next morning "to the hospital."

THE HOSPITAL IS ALWAYS READY FOR YOU.

Patients suffering from ordinary ailments or diseases commonly enter a general hospital through the "out-patient" department. Furnished with a governor's letter, which is always obtained readily enough, anybody can secure the advice of the physicians and surgeons on duty for the day, and if they decide that his or her illness is of such a character as to require treatment inside the hospital, the patient can enter at once, providing there be a vacant bed. Entrance may be also obtained on the special recommendation of the physicians and surgeons; but there is one essential difference between medical and surgical cases, between illnesses and hurts, that persons suffering from the latter can claim attention at any time. The hospital door is always

Digitized by Google

open to accidents. Night and day, Sunday and week-day, the porter stands at the door ready to pass in and conduct to the house-surgeon anyone appearing with an accidental wound; and no matter how trivial the injury may be, and without any reference to the dress of the applicant, surgical attention is immediately given, and no demand pressed for a letter of recommendation or for payment. A general hospital makes no distinction between the thriftless and the thrifty in the hour of need. Hour after hour, day after day, year after year, it stands ready to bestow the best medical advice and the kindliest compassion on all who may cross its threshold. A man may pass a whole lifetime, and never think once seriously about the hospital, or bestow a sixpence upon it. Yet all this while the door has remained open night and day ready to receive him should bodily harm ever befall him, and the benevolence of the more thoughtful has kept in motion the machinery of medical talent and nursing skill, in spite of inadequate funds and lagging contributions.

IS YOUR CASE LIKE DYER'S?

Tom Dyer, the mechanic, confessed to himself, as he was jolted along in a cab to the General Hospital, that his contributions to the Hospital Sunday Fund had never gone beyond a copper or two, and not even that when he happened to stay away from church on the annual anniversary; but he thought he was not quite so bad as Jack Brown, who made it a joke that on Hospital Saturday he always rushed to a "pub" the moment he knocked off work, and stayed in the bar till dark, to avoid the solicitations of street collectors on his way home. Sometimes Brown got drunk before dark, and went home reeling, in which case he admitted that he might have given something to the Hospital Saturday people "unbeknown to himself," but he would take his oath he never had while sober. No such levity as this rested upon the conscience of Dyer, nor, in fact, did his reproaches go very deep, as he had a vague impression that the hospitals were more or less richly endowed by the wealthy classes, or were kept going by their annual contributions. He wished at one moment he had given a silver threepenny-piece at the collections instead of a copper; and then he thought that the Hospital Sunday collection taking place only once a year, he might have spared a shilling; but he was really too ill to go far into the *pros* and *cons* of the subject. For the moment his eye was more sensitive than his conscience.

ARRIVAL AT THE HOSPITAL.

Arrived at the hospital, one of the porters assisted him to alight and conducted him into the house-surgeon's receiving-room. At all general hospitals, in proportion to their size and wants, there are a number of house-surgeons and house-physicians, who take it in rotation night and day to receive and treat any cases admitted requiring immediate attention. In the General Hospital[1] there were five resident house-physicians and five resident house-surgeons, besides a couple of resident dressers. Being situated in the heart of a crowded manufacturing district, its staff was necessarily large. The house-surgeon had just disposed of a sprained wrist case as Dyer entered the room—a large, warm, and well-ventilated apartment, with a lavatory in one corner, cases of surgical instruments on the walls, tin boxes containing bandages and antiseptic dressings on the side tables, and a general litter of bottles of drugs and surgical appliances; everything handy and ready for use, and presided over by the house-surgeon, middle-aged, prompt, energetic, and swift in decision; the dresser, a budding student, assiduous and helpful; and a nurse, hovering quietly about, and anticipating every wish of the surgeon in preparing the patient for examination; retiring afterwards to the background to put in their place or clean any things used in dealing with previous patients, at the same time keeping on the *qui vive* to render fresh aid if necessary. "A severe punctured wound," said the house-surgeon, after examining the eye and eliciting particulars of the accident. "You will require immediate treatment as an in-patient, and will be taken to the Ophthalmic ward at once."

DYER EXAMINED BY THE DOCTOR.

The well-known ophthalmic surgeon and professor of ophthalmic medicine and surgery was going his rounds when Dyer entered the ward, and had him conveyed to a small darkened chamber, where at the close of a prolonged inspection he warned him that it would be necessary to remove the eye. "All the beds in the Eye ward are full, and you cannot be accommodated there; but they are taking on in the Roderick ward below, and as you will be out by the end of a week, we can put you among the surgical cases. Don't distress yourself about the eye; the other is sound and healthy, and you will be able to get on with only one eye as well as Nelson." Applying something to relieve the pain, he sent him into the Eye ward, telling him that he had better remain there for the present. The Eye ward of the General Hospital was not a "bandaged" one, but remarkably cheerful. It contained thirty beds, disposed in two rows, one row subdivided by the fireplace, the other by a large table decorated with flowers in vases or growing in pots, which took off one's attention from the dressing tins placed upon it. The dark green walls were relieved by coloured pictures from the *Graphic* and *Illustrated London News*, and the sweet singing of a linnet prevented the patients from being depressed by the monotony of sullen silence. Only a few of the patients were in bed. The rest were sitting or standing about, discussing the contents of a newspaper which a patient with eyes nearly cured was reading aloud to a group. Near the fire, two lads, each with an eye bandaged, were playing chess.

AMUSING THEMSELVES IN THE EYE WARD.

A nurse conducted Dyer to a seat near a window overlooking a crowded street, and next to a man lying on a bed with both eyes shaded. Asking Dyer what he was suffering from, he went on to talk about his own case, saying that he had been in the ward for a month owing to injuries received during an accidental explosion of gunpowder. For three weeks of this time both eyes had been bandaged, and he said that he should have been tormented out of his life by anxiety and "nothing to do," but for the amusement he derived and imparted to one or two others by keeping his mind employed with a celebrated system of memory. Having recently learnt it, he was able to repeat in rotation, after another patient had described all the articles in the room, the whole at a stroke; then he recited page after page of the books he heard being read, and by these and other exploits made himself quite a hero. He astonished Dyer by getting him to repeat the names of all the men and foremen at Dudgeon's he could remember. "When I'd done," related Dyer, describing the event afterwards, "he said, 'Now start again and repeat the lot in the same order.' Of course I couldn't, for I didn't know whether I'd put Brown first or Robinson, upon which I'm blest if he didn't gabble the whole lot off in a string, just as I'd said them, though there were more than two hundred, and I'd only said their names once."

THE RODERICK WARD.

About 6 o'clock Dyer was conducted below to the Roderick ward on the lower floor, and was informed that a bed would be at his disposal there till he left. The ward was double the size of the one he had quitted, and held in all sixty beds, separated into two sets of thirty apiece by a broad lobby, containing the kitchen, scullery, dispensary, lavatory, and other offices of the ward, which virtually rendered it two wards of equal dimensions, since, although the gangway ran straight through it from one end to the other without door or partition, the lobby compressed it a little and narrowed the view from each section. The bare boards of the floor were as white and as clean as any trencher in olden times, and were relieved in colour by the red counterpanes on the unvalanced beds, of which there were fourteen on the fireplace side and fifteen on the other. At the back of each bed were blue cotton curtains, so suspended on a half hoop bar as to move easily round and partly enclose the bed, affording the patient privacy if needed, and enabling him to screen himself from the rest of the ward if undesirous of looking out upon that little world of suffering. Suspended from this bar, also, was a sheet of blue paper, foolscap size, containing the name and disease of the patient below, and

[1] For the sake of giving greater weight to the facts in this narrative, the whole of the statistics of the General Hospital are taken from the latest data obtainable at the London Hospital, Whitechapel, the largest of the metropolitan hospitals, having over 700 beds. To have adopted fancy figures, worked out from the data of all the hospitals, would have been to vitiate the value of the statistics; hence, without any intention of invidiously treating the rest, the London Hospital has been selected, being the largest, as the one to furnish the statistics, while the general features of the General Hospital are taken from all the principal hospitals, strict attention being paid to keeping the description well within the mark, and rendering it a practical matter-of-fact account, rather than a picture of the ideal.

Digitized by Google

particulars as to his treatment and diet. Behind the bed the buff-coloured wall was adorned by rows of beautiful engravings and chromo-lithographs, and at the end of Dyer's section there was a magnificent oil-painting, "Joseph revealing himself to his Brethren," the munificent gift of a benevolent R.A. Beneath this a set of suspending shelves contained a library of forty volumes, the lowest shelf partly hidden by a number of beautiful ferns on a table. A little to the side, singing in the window, was a mule canary, and not far from the warbler was an aquarium full of goldfish, placed in a window recess. Between each bed was a pretty white pine locker, on noiseless wheels, with a cupboard in front for any articles the patient might require to stow away, and a rack behind for his towel and medicine.

THE PATIENTS AND THEIR NURSES.

Expecting to hear groans and lamentations in a surgical ward, Dyer was surprised at the calmness prevailing. Doubtless pain existed in most of the beds, or else that discomfort arising from long lying in one position which is akin to pain; but, generally speaking, the bandaged heads and arms protruding outside the counterpane, and the legs in splints buried beneath it, were quiet enough, and the outward expression of bodily wretchedness was chiefly confined to a twitching of the face, or a slight movement of the bedclothes. There is as much manliness and fortitude displayed in bearing pain in the ward of a hospital as on the field of battle. Dyer soon discovered that the female attendants in the ward, in their cool print dresses and white aprons and dainty white caps, were divided into nurses and probationers—the latter apprentices to the noble craft of nursing; and that supervising both was a Sister, distinguishable from the rest only by long lappets to her cap and by an air of responsibility and authority. Above the probationers, nurses, and sister, was the matron, a buxom lady, with but a slight variation in dress to mark her rank, and who had such a broad bright face, and such a good-humoured smile, that the lowest felt at once at ease in her courteous presence. Her authority was maintained by just the faintest firmness of tone, which never varied, except to level a short, cutting, indignant reproach at any probationer or nurse unusually remiss in her duty. It was not often that this was the case, so firm and vigilant was the sister, and its rarity in the Roderick ward was a matter of frequent commendation on the part of the matron.

SISTER AGATHA.

The sister was young and of attractive appearance, and had entered the hospital as a probationer, working her way up to her present position. She was deeply spiritual, and with that happy unconsciousness of her piety which has so rare a charm in women who devote themselves heart and soul to any stirring sacred mission. In the whole hospital there was no hooded or black-robed devotee of any religious nursing order, and if the rest of the sisters were as devout as Sister Agatha there could have been no need for them. It was Sister Agatha who read the prayers in the ward night and morning, kneeling at a prayer-desk and reading two short prayers in a clear and sonorous voice, then singing, without referring to any music-book, two or three verses of a favourite hymn. The prayer services were obligatory in all the wards; but the singing was a specialty of the Roderick, and when the sun shone in upon the ward and Sister Agatha was singing "Jesus, lover of my soul," in the sweetest of voices, Tom Dyer, the mechanic, fancied that the mule canary listened in prayerful sympathy, and that the gold fish ceased their placid swimming till she had done.

THE WARD AT NIGHT.

At 8 o'clock the gas was turned down, and the ward subsided into quietness for the night. For Dyer there was very little sleep at first. He was in a fright, as you and I would have been, at the coming operation. Then there were thoughts about the future that were not of the brightest—"who would take on a one-eyed chap when even two-eyed mechanics were at a discount?" Afterwards the empty bed at the side worried him: had anybody just died in it? would he himself die? would he be awakened at night by tramping men bringing in, as an occupant, some victim, like himself, of an accident? When a night nurse hurried along the ward he imagined [illegible] body must be dying, and the moans of a poor fellow [illegible] of the ward—a bird-fancier, whose [illegible] by a cat—filled him with feelings of [illegible] when the house-surgeon [illegible] something to alleviate the man's sufferings. At last he fell asleep, and did not awake the next morning until the night nurses were gone, and the probationers were taking round the 7 o'clock breakfast of cocoa, and tea, and other nourishment, varying in individual cases, to the different patients. As he was to be chloroformed at 10 o'clock, the surgeon had left orders that he was to take no breakfast in the morning. While the rest of the patients were having theirs, the scrubbers came to wash the floor, and afterwards there was a general cleaning and tidying of the ward till half-past 9 o'clock, when he dressed, and a ward clerk—a very good-natured young fellow, although a regular "masher" in dress—conducted him upstairs to the Eye ward. He did his best to raise Dyer's spirits. Thanks to his friendly words, Dyer entered the waiting-room alongside the operating theatre with a firm and confident tread, and quietly bided the time for the operation.

DYER UNDER CHLOROFORM.

There were several minor operations before Dyer came in and stretched himself full length on the couch, while the assistant-surgeon promptly prepared him for the operation. With equal quickness the house-surgeon placed a square piece of lint in front of the patient's nose, about two inches from it, and began dropping chloroform from a small ounce bottle. This he increased, until the lint became quite saturated; then he removed it, and placed firmly over Dyer's nose a Clover's inhaler, from the bag attached to which the patient drew in deep inspirations of ether. At the outset Dyer manifested a deal of muscular excitement, but gradually it passed off, and he appeared to fall into an uneasy slumber. The house-surgeon on one side kept the inhaler fixed to his nose, watching his face intently, with his finger on his pulse; while the assistant on the other side held the electric light close to the wounded eye, from which the bandage had been removed. "Ready?" demanded the operator. "Ready," replied the house-surgeon. Deftly inserting an extender in the eyelid, which extended the size of the orifice, the operation commenced. At last, after careful dissection, he severed the eye from its connexions, and holding it out on the palm of his hand for the spectators to look at, observed, "The wound went right through; there was no hope for it."

3560 EYE OPERATIONS IN ONE YEAR.

"And so this is the patient who had his eye taken out," remarked, a few minutes later, an old clergyman visitor to the house-surgeon, as they both looked in the doorway of a dark room, where Dyer still lay stretched out on the couch, with a nurse sitting alongside him to watch his recovery from the chloroform. "Who are you looking at?" suddenly demanded Dyer, starting up. "I tell you I'm not going to have my eye out this morning." The nurse pressed him down quietly, and the house-surgeon, remarking that Dyer was "just coming to," led him into the operating theatre, where he showed him the electric light, and explained the uses of the various instruments. "What we do," he said, in course of conversation, "is on a small scale compared with a regular Eye hospital. I was at the London Ophthalmic Hospital, Moorfields, for several years. There they perform, on an average, nearly ten operations regularly every day—3560 in the course of a year. The attendances of out-patients amount to nearly 125,000 a year. The 100 beds there are always full, and they pass through the hospital every year over 2000 patients!" "Dear me!" exclaimed the clergyman. "Yes, and they not only cure poor people's eyes for nothing, but they give away spectacles to such as seamstresses, poor working men, and others, who cannot afford them. On an average, each pair of spectacles costs the hospital 7*s.* 6*d.*, and they gave away nearly £200 worth last year. Then, to those who *can* afford them, they try their eyes, and sell them the spectacles at almost cost price, so that a working man can be sure that he has got the right sort, and is not cheated with inferior spectacles. In a smaller way we do the same thing here, the Samaritan Fund providing for the gift of spectacles to very poor people." "What a very good idea," said the clergyman. "I was thinking of preaching a sermon on the case of the poor man who was married at my church, and I think I shall invite special donations on behalf of this fund." "I thank you, we shall be very grateful. A Samaritan fund appeals to every Christian."

THE EYE SURGEON WHO ENDURES MUCH.

"Now, tell me," demanded the clergyman, "don't you find it trying, having to pass 3560 operations through

Digitized by Google

our hands every year?—there must have been a great train on the nervous system." Remembering that during Dyer's operation the house-surgeon was on his knees quarter of an hour, with his head and eyes within few inches of the operation, such intense application, continued day after day throughout the year, while ving all the while amidst the dejected sufferers of eye iseases, must involve a strain appalling to those whose ives are spent in more pleasant places. "There was a train," the surgeon admitted, and then he went on to escribe the case of a house-surgeon in a great London eye ospital, who, while working thus daily for others, was imself attacked by an incurable eye disease, which in ime—a year or two ago—made him blind. Still, in spite f this terrible affliction, he kept at his post to the last, elping cheerfully to save the sight of others while his own vas gradually perishing. What an example to those who would stay the course of the universe if they happen to ave a cold, or rail at Providence if afflicted for a couple of days ith a pimple! Working on, while growing blind, to the ast! The annals of every London hospital are full of imilar cases of heroism.

AFTER THE OPERATION.

As soon as he had recovered, a little nourishment was given o Dyer, and having received the congratulations of the man ith shaded eyes, who, to please him, recited afresh the names f the two hundred men at Dudgeon's, he was conveyed gain below to the Roderick ward. The pain arising from he wounded eye had departed with it, and, beyond a slight eeling of soreness, there was nothing now to trouble him. t the recommendation of Sister Agatha he had a nap in ed, and awoke about mid-day in a tolerable mood for his inner. This was served round to each patient by the probationers and nurses, who flitted right and left from the obby, and soon supplied each sufferer with his ordinary llowance of roast meat, vegetables, and milk pudding, ogether with such stimulants as had been specially ordered y the doctor. The ordinary diet was varied by fish, chops nd steaks, mutton-broth or beef-tea, and other articles; ut in every case it was served up hot and clean, and in a anner to please the most fastidious invalid. After dinner yer lay on his bed for hours in that happy, peaceful conition which commonly follows a severe operation if the atient knows that the whole of the worst is behind him, nd that in front lies swift and certain recovery. Peace fter pain—is there any other peace so beatific as this? yer felt as though he had had a fresh lease of happy life onferred upon him, and was encouraged to hope that his peedy recovery might be quickly followed by fresh emloyment. If Nelson had got on with only one eye, why night not he? At any rate, the wounded eye would trouble im no longer, and in two or three days he would be discharged from the ward, and in the meanwhile it was very leasant to lie there on his back, lazily watching what was oing on. At the worst, the bright, sunny ward was a leasant contrast to the black and gloomy workshop at udgeon's.

THE DEATH OF THE BIRD-FANCIER.

Among other things, he noticed in the afternoon a contant movement towards the bird-fancier's bed at the remote nd of the ward. In the morning a piece of felting had een unrolled along the length of the passage-way between he beds, to deaden the sound of the footsteps on the bare hite floor. The house-surgeon looked in several times; ister Agatha kept her gaze constantly in the direction of he bed. As the day wore on, and the sun shone brightly nto the ward, the flowers seemed to grow fresher and more eautiful, the pictures on the wall appeared full of animaion—one almost expected to hear the British soldiers at uatre Bras above Dyer's bed shout at the rushing enemy—hile the mule canary piped its song shrilly. Thinking the oise might worry the sufferer, Sister Agatha ordered it to e removed to another ward, but a feeble sign from the bed rrested the departure of the songster, and, apparently by equest, the cage was placed on a locker alongside the bed, rom which a hand was presently extended caressingly. Later on the nurse enfolded the bed with a couple of crimson creens, behind which afterwards disappeared the Chaplain nd a rough-headed middle-aged man in a coarse grey weed suit, who followed the former awkwardly, with a ubdued manner evidently foreign to his habitual bearing. 'It's the bird-fancier who was brought in last weak—run over by a van," said a probationer to Dyer, in reply to an inquiry he put while she was administering to him his medicine. "He is not so well to-day, and his mate is visiting him." "Not so well to-day" is a quiet hospital way of saying that a patient is sinking.

SISTER AGATHA SINGS "ROCK OF AGES."

Tea-time came and passed. The probationers tidied up the ward for the night. Sister Agatha said prayers in the usual course, and Dyer thought that he had never heard anyone sing with such tremulous sweetness "Rock of Ages, cleft for me." She sang softly that night, but every word could be heard in the remotest part of the ward. The nurses and probationers were moved to tears; the matron, who had entered the ward at the second verse, stood motionless and pale by the door; the "masher" ward clerk fidgeted into a shadowy part of the lobby to conceal his discomposure; while, altogether unconscious of the effect she was producing, and thinking only of the dying bird-fancier, Sister Agatha sang on, with a voice trembling with emotion, to the final verse—

> "While I draw my fleeting breath,
> When my eyelids close in death,
> When I soar through tracts unknown,
> See Thee on Thy Judgment Throne,—
> Rock of Ages, cleft for me,
> Let me hide myself in Thee."

As she finished, the mule canary, thrilled by the deep silence that followed, burst afresh into song.

THE BIRD-FANCIER'S BEQUEST.

While the hospital helpers were yet rolling the mortal remains of the bird-fancier along the dim and dismal basement passage to the mortuary, the matron, in passing Dyer's bed, whispered to a nurse, "What do you think the poor man did this afternoon? He bequeathed the whole of his birds to the hospital." The whole of his pets! They were as much to him, though he lived in a Whitechapel slum, as the choicest art treasures are to a connoisseur dwelling in the most sumptuous residence in Kensington. All he loved he gave to the hospital, to gladden and cheer the patients, and as a dying expression of gratitude. In its way, his bequest was as superb as the gift of a gallery of pictures by a dying millionaire.

VISITING DAY.

The next day was Sunday. In the afternoon the hospital was flooded by visitors. The moment 3 o'clock had struck they poured up the staircases and along the corridors to the various wards, carrying flowers, toys, and brown-paper packets for the patients. Before long, in every ward the brightness and lightness of the place was broken by black patches—groups of black-dressed people standing by or sitting on the beds; for black is not simply the hue of Sabbatarian decorum and respectability with the toiling masses, but is considered *de rigueur* to the uninitiated in visiting a hospital. Forming their impression of the inside of a hospital from what they see of the gloomy exterior, they prepare themselves for a sort of prison, supervised by sour-faced nurses, and officials ready to pounce upon and suppress any expression of light-heartedness in the shape of a laughing face or highly coloured clothing. It is quite a revelation to them to find gaiety encouraged, brightness made an art by the matron and nurses, and sombre respectability cuttingly disregarded.

THE PATIENTS' HOLIDAY.

Visiting day is the patients' holiday, and it is impossible to go through the wards while the friends are hanging about the beds without feeling that it is enjoyed far more thoroughly than many a holiday outside. The two hours allowed for the carnival are none too long for the eager and animated imparting of the latest family news, and for the discussion of the patient's particular disease or hurt, and the mode of life in the hospital. Here and there a bed may be passed, silent and unvisited. Perhaps the patient has no friends; perhaps they are too poor to visit the sufferer often. In some cases a patient will, if of a cheerful disposition, extract amusement from watching other patients' friends, some of whom, if they have been frequent visitors at the ward, may also, out of good nature and desire to cheer, come and pass a word or two. Other patients, rendered peevish by pain, and naturally of a lacrymose disposition, openly display their disappointment at being left deserted and solitary amidst so much animation; and it is here that a sister or a nurse, flitting about a ward, may render the service of a good angel in pausing for a few minutes to cheer the sufferer by a timely chat.

Digitized by Google

VISITING THE UNVISITED.

In some of our London hospitals there is a touching tradition of a great-hearted man, who used to devote his time to visiting the unvisited patients. Unostentatiously he passed through the wards, and whenever he saw a solitary patient who seemed sad and forlorn, he would sit down and talk till he had brightened up the sufferer; and then, leaving a newspaper, or a magazine, or a book behind to continue his cheering influence after he was gone, he would pass on to someone else in want of consolation. He never "talked religion," although his conversation showed him to possess deep spiritual feeling, and he never gave away tracts; his equipment consisting of a kind tongue and a bundle of Sunday magazines, or, if on week-days, some evening newspapers, together with a reserve of a few new books, which he carried in his pockets. In many of the hospitals even his name was unknown. He called himself, jokingly, Mr. Jones, or Smith, or Robinson, when requested to give a name, and repressed further inquiries by a trifling contribution to the hospital funds. Who he really was, and where he came from, remained unknown to the end. The officials he rarely talked to if he could avoid it, and as soon as his mission was understood they allowed him to roam through the wards unmolested. For nearly two years his visits regularly lasted, and then suddenly ceased, probably through the death of this kind-hearted, unassuming Samaritan. His mission died with him, but may it not have been more glorious while it lasted than many a Press-puffed pretentious piece of charity?

A DEPUTATION FROM DUDGEON'S.

Dyer was not among the unlucky ones. He had not only his wife and daughter to cheer him, but also that good-for-nothing Jack Brown, who, with another man and a foreman, appeared as delegates from Dudgeon's to visit him on behalf of his fellow-workmen. These rough and sturdy fellows, who shouted lustily enough their workshop jokes, and had made their voices heard at many a political meeting at Poplar, fidgeted about by the bedside, and kept talking about subjects different from that they had come expressly about, until Mrs. Dyer, after many hints and nudges, goaded Jack Brown into saying, "Well, Dyer, old chap, we come to tell you——." Then suddenly stopping, he said, "Here, missis, you must tell him the rest." Stooping to kiss him, his wife ejaculated tearfully that the day before, hearing he had lost his eye, the men at the works had started a subscription, which had resulted in £9 12*s.* 4*d.* being collected on his behalf. "It is not much," said the foreman, apologetically, "but it will keep your mind easy for a few weeks, and then something else may turn up to help you along."

PRESENTS FOR THE WARDS.

After a little talk the men began admiring the ward. "Roderick" was quite brilliant that afternoon. Most of the visitors had brought bunches of flowers, and several of them flowers in pots. The gold fish maintained a constant chase after one another in the aquarium, stimulated by the fountain playing blithely overhead, while the mule canary trilled in the corner, provoking many a glance of admiration from the patients' friends. "If I had thought they'd been acceptable," said the foreman, "I would have invested in a flower or two for the ward. Yesterday, outside Dudgeon's gate, they were selling big flowering geraniums to the men at fourpence a pot, and some fuchsias, like a tree—as much as you could carry home—for ninepence or a shilling. One of those would have looked well in the ward, if one had known it." "If one had known it," repeated the Chaplain, who, in passing through "Roderick," had seen the men casting admiring glances along the ward and had overheard the words of the foreman. "You see now how much good remains undone through ignorance. The hospital is always thinking of you, and preparing for you; you may be struck down at any moment and be brought here. Now, how often do you think, in return, of the hospital?"

GOOD ADVICE FOR EVERYONE.

"To tell the truth," said the foreman, "I've never thought about it at all. I hope I never may have to attend one." "I hope so too," rejoined the chaplain, "for your sake; but you're not sure. An accident occurs only now and again, you may say, but the number soon mounts up. At this hospital alone we dealt with over 8000 last year. Here are the figures—1572 fractures, 3491 wounds, 1126 contusions, 185 sprains, 171 dislocations, 761 burns and scalds, 94 cases of hernia, 34 dog-bites, 107 cases of hæmorrhage, 7[illegible] cases of retention, 34 of foreign bodies in the throat [illegible] 860 cases of inflammation from injuries, and about 2[illegible] various, making a total of 8707. Of that number, 2000 all [illegible] 8 were brought into the hospital, and provided with [illegible] same comfort and care as your friend lying there. Is [illegible] that a tremendous number for a single hospital? Yet th[illegible] is the way the hospitals keep working for you throug[illegible] the year in every district in London—not all to the sa[illegible] extent as this, but invariably working to the full stretch [illegible] their powers."

£50,000 A YEAR TO MAKE UP.

"It must cost something to keep them all going," said t[illegible] foreman. "Yes, and being mainly dependent on voluntar[illegible] subscriptions, the hospitals have a hard struggle to r[illegible] along. Our fixed income is only £15,000 a year, and we ha[illegible] to make up nearly £50,000 a year." "I suppose you ge[illegible] good many legacies, sir," observed the foreman. "Not [illegible] many as the wealth of London might lead you to think; but you must know that it is not the £100 bequests that keep a hospital going—it is the sixpences, [illegible] shillings, and the half-crowns of the general publi[illegible] together with the guineas of annual subscribers. Fri[illegible] you who toil we look for an occasional subscription, not [illegible] a matter of charity, but out of common fairness. When yo[illegible] take a ticket for a long journey, the railway clerk often sa[illegible] to you, 'Will you insure yourself against accidents? For [illegible] penny or twopence you can insure so much a week in t[illegible] event of being hurt.' Now, each in-patient costs, on a[illegible] average, nearly 3*s.* 9*d.* a day, or 26*s.* a week, including the maintenance of the hospital. We're spending a[illegible] that rate on your friend lying there, and we may b[illegible] spending it on you to-morrow or some future time. Yo[illegible] are ready enough to spend twopence to insure the recei[illegible] of a few shillings a week in going on a single long journe[illegible] Now, here is a sum of 26*s.* a week which the hospi[illegible] stands committed to spend on you if you are brou[illegible] into its wards injured and helpless. Don't you think, therefore, that in common fairness you ought to pa[illegible] something in the shape of insurance money in return? A shilling a year on Hospital Sunday, is surely not too mu[illegible] for every working man to subscribe to keep up hospita[illegible] which are ready to spend nearly £70 a year to cure him if [illegible] is brought into their wards injured or ill. Why, my go[illegible] friends, if you were on a platform, and a man fell under t[illegible] carriages and was terribly mangled, and another man, burs[illegible] ing through the crowd as they bore him away, were t[illegible] exclaim, 'Here is a purse with £20; spend all on him t[illegible] cure him; and if he wants more, there is a blank cheque f[illegible] the remainder.' If a man did that, the crowd would che[illegible] him out of the station. Yet the hospital is doing that ever[illegible] day, and instead of cheering, the public, with sighs, fill [illegible] the bags on Hospital Sunday with coppers and threepenny pieces. Isn't that so? The hospital gives ungrudging a[illegible] all the year round—365 days; the public find it har[illegible] to give grudgingly only once—on Hospital Sunday."

NOT CHARITY, BUT SELF-INTEREST.

Observing that the group looked a little abashed, the chaplain placed his hand good-humouredly on the foreman's shoulder and exclaimed, "Well, if I go on at this rate, you will complain that I am preaching a sermon. You came here to cheer up your friend, not to be lectured; so don't let me spoil your chat any further. But remember this, when you are asked to subscribe to the Hospital Sunday Fund, don't say to yourself, 'I am giving a shilling out of charity,' but rather, 'I am giving a shilling to ensure that, if I get injured during the year, I shall find awaiting me a well-organised hospital, a comfortable ward, a soft bed, the kindest of nurses and doctors, and a managing staff determined to begrudge no expense, and to do the utmost in their power to make a whole man of me again, and restore me in good health to my family.' That's the view I want you to take of it—not charity, but self-interest, and common fairness between man and man. Good-bye!" Shaking hands with them, he passed on, but returned before he had gone many steps, and said to the foreman, "That was a very kind idea of yours wishing to bring a big fuchsia to the hospital. Now, some of these days, when you can spare a nice potted flower from your garden, and are passing this way, it would be in this case charity, not self-interest, to leave it at the lodge addressed to the house governor, to be placed in one of the wards. Look how bright the kindness of people has made this ward; the humblest can help, with a picture or a

Digitized by Google

flower, to keep it bright and cheerful for our sufferers." "Ay, ay, sir, I'll bring a beauty next Sunday," exclaimed the foreman earnestly. "Tom won't be here, then," said Mrs. Dyer, as the Chaplain walked away. "He's to be out on Tuesday or Wednesday." "Then I tell you what, old man," declared the foreman, addressing Tom Dyer, "you and I will come together if the missis will let us, and we'll put on the table a couple of big fuchsias that will make it look like a flower-show."

HE WASN'T IN "LLOYD'S."

As the Chaplain proceeded along the ward, a patient in one of the beds angrily tore a newspaper in halves and threw it on the floor. Picking it up, he said to the man, "You seem annoyed with something in this paper?" "No, sir, it's not what's in it but what isn't in it that annoys me. I fell from a scaffold forty feet yesterday and broke a leg, and they haven't put it in 'yesterday's summary,' yet they've been and gone and put in another man who only fell twenty feet and only broke his collar-bone. I've taken in *Lloyd's* regular every Sunday for twenty years. Do you think that's fair?" "Well, I don't know," replied the Chaplain, good-humouredly, "but I don't think the paper's to blame. If you'll let me have it, I'll patch it up and send it back to the ward to-morrow—the other patients might like to read it. Good afternoon—I see I am wanted at the end." *Lloyd's* publishes every Sunday a column of horrors, detailing the accidents of the day before. It is not very agreeable reading, but the masses like it, and when a regular reader gets injured on a Saturday he is often, if sufficiently recovered, as impatient to see if his name is in "yesterday's summary" as a fashionable lady is to see the notice of her party or her grand dinner in the columns of the *Morning Post*.

SMUGGLING BRANDY INTO THE WARD.

The reason the Chaplain hurried away was because his roving eye had detected a visitor surreptitiously slipping a bottle under the counterpane of a bed at the end of the ward. The introduction of liquor into the wards of a hospital is strictly prohibited, and in the event of detection the visitor is immediately expelled, and the repetition of the offence leads to the expulsion of the patient if in a removable condition. In spite of this necessary rigour, patients' friends, from a mistaken feeling of kindness, persist in trying to evade the regulation, and it was to prevent any trouble occurring that the Chaplain himself took the present case in hand. Walking carelessly up to the bed, and placing himself between the visitor and the patient, he made a few commonplace remarks, and then, passing his hand casually across the counterpane as if to smooth it, exposed one end of the flask to the discomfited couple. Covering it over again, he said to the patient's friend, "What is it—brandy or whisky?" "Brandy. I——."

A DONATION IN KIND.

"Quite so, quite so; I don't want any explanation," interposed the Chaplain, fearing the man's excuses might result in a strain on the truth. "It was kindly feeling that made you bring that into the place, and there need be no disguise about the matter. The hospital prefers, if possible, to receive donations in cash, but it does not object to presents in kind; and if you will, as I know you will, present the flask of brandy to the Sister, she will be very glad to add it to the stores of the hospital. In this place we include brandy with the drugs, and the doctor stints no one spirits, wine, or beer, if he considers stimulants essential. Last year we spent over £400 on spirits, over £100 on wine, £350 on beer, and £2700 on milk. A part of the beer goes as 'diet,' the rest is issued as medicine; but the whole of the liquor is consumed by the patients only. So you see we are not stingy to the inmates. And having so much to buy, we are always grateful when a rich man bequeaths us his wine-cellar for the use of the patients, or when we get even what you might think the trifling donation of a flask of spirits. This, I suppose," removing the flask from its place and measuring its contents with a critical look, "cost a shilling. Now, tell me, why is it that people like you hesitate to give a shilling to hospitals once a year, and yet do not mind spending a shilling on a present of this kind when you visit a patient?"

CONVERTING AN EVIL-DOER INTO A BENEFACTOR.

Beckoning to Sister Agatha as she passed, he placed the flask in her hands, and said, "This kind person did not know what to bring to cheer his comrade in bed, and made a desperate guess at brandy, which is supplied by the hospital. He hopes you will kindly look on it as a donation, and I think I am correct in suggesting that if he wanted to bring anything another time, you would be very glad of an illustrated paper, or a book, or a set of draughts, to cheer up his friend during his stay in this place." "Most certainly," replied Sister Agatha, with a smile. "Many thanks for this." And as she went off to her room with the confiscated flask, the Chaplain continued, with a pleasant smile, "It is so easy to impart pleasure with a little thoughtfulness. Now your shilling, handed to the Sister, would have kept your friend regularly supplied with the daily paper for a fortnight, and when he had finished with it every day, it would have given pleasure in the afternoon and evening to the other patients in the ward. How much more pleasure that would have been than a few nips of brandy, which might have thrown your friend back, and perhaps killed him. But never mind, you meant well, and if you will take my advice, next time you wish to cheer a friend in hospital consult the Sister, and you will be astonished at her wonderful knowledge of the ways to do it, at a far less cost than your flask of brandy." Having thus put them at their ease, the Chaplain nodded a good-humoured farewell, and quitted the ward.

THE EMPTY BED IS FILLED.

Dyer fell asleep directly after supper, and he did not break clear of the doze until midnight. He then observed, while tossing about, trying to get asleep again, that the vacant bed by his side had at last found an occupant. Throughout the night the new-comer was constantly visited by the nurse on duty, and during one of the later inspections towards the morning, Dyer overheard her say to a probationer that the sleeping man had met with an accident on the Underground Railway the night before, having slipped between the train and the platform while alighting from the carriage, and sustained a fracture of the arm and some bruises. One of the latter had evidently been accompanied by a laceration or a cut, as the patient's right cheek was striped with a piece of plaster. Twisting himself round, in order to bring his remaining eye to bear more completely on his neighbour, Dyer started, stared, and ejaculated involuntarily, "Why, I'm blest if it isn't the old governor!" "Who?" demanded the nurse. "What's his name?" exclaimed Dyer, excitedly, in reply. "Dudgeon," answered the nurse, examining the invalid's passport, suspended over his head.

DIVES IN THE RODERICK WARD.

"I thought I wasn't mistaken," said Dyer; "that's my old master—Dudgeon—who used to own Dudgeon's Works and sold it to a company. What's he doing here? He was in Italy when we heard from him last. Well, I *am* blest, to think——" "Hush!" interposed the nurse; "you will wake him if you talk too loud. Just tell me quietly who he is, and we'll communicate with his friends. We knew he was a gentleman by his clothing when he was brought here last night, but he had no card-case in his pocket and we took his name from his linen." After that, you may be sure Dyer had very little sleep. It was a revelation to him to find that the rich found their way into hospitals as well as the poor. "I thought they only subscribed to them for us chaps, he said to himself; "but it seems that they want the hospital at times as much as we do." Then he tried to imagine what Dudgeon would say and do when he woke up, and found himself lying in bed a few yards from one of his old workmen, and whether the liveried butler and footmen would be allowed to come and wait upon him in the ward, and what the hospital generally would do when it found that it had such a distinguished man as Dudgeon within its walls. "Why, if he liked," whispered Dyer to the nurse, "he could keep this whole place going himself, and still have enough a year to live on in Mortgramit Square!"

NEARLY DECAPITATED ON THE RAILWAY.

When Sister Agatha put away the prayer-book after morning prayers on the library shelf, alongside "King's Solomon's Mines" and "Treasure Island," and returned in the direction of her room, Dudgeon beckoned to her, and said, "How very nice! Kindly thank the nurses who took charge of me last night; and accept my own thanks for the hymn you sang so sweetly. More than anyone, I should be grateful this morning for my marvellous escape last night." "Was it so remarkable as that?" asked Sister Agatha. "Quite astonishing. I thought the train had stopped, and fell as I alighted, first on the platform and then between

Digitized by Google

a couple of carriages. Somehow my head got on the line and the wheel rolled on till it pinned the nape to the metal; then it stopped; an inch more and I must have been decapitated. As it was, I was jammed so tight between the wheel and the rail that they had some trouble in getting my head out. The suspense was awful, and I can just remember being placed on the platform, and then must have become insensible, for my arm was being put in a splint by your surgeon when I came to again." "God was very merciful!" "And man merciful too; for when I was brought here everything was lying ready to receive me, and I was examined, mended, and put to bed as promptly and with as much kindness and consideration as my own family could have shown me. I presume you treat all alike in this hospital—the patients in this ward were all treated like me?" "All of them. In the General Hospital no difference is made between rich and poor; and the coalheaver who is brought crushed and bleeding is treated just the same as any gentleman knocked down by a cab. We make no difference between master and man; but of that you can judge for yourself. In the next bed is one of your own workmen, who has been here several days. He will be the best authority in this matter. But you had better remain quiet until the surgeon comes round, and I would advise no more talking till then. Is there anything I can do for you in the meantime?" "Nothing, except to request the House-Governor to pay me a visit at his convenience."

ARE WE NOT ALL LIKE DUDGEON?

When the House-Governor came up later, Dudgeon said to him, "I am much obliged to you for your kindness in receiving me here last night, and putting this left arm of mine into gear. I certainly never thought I should some day spend a night in a hospital. That's an Irish way of putting it, but you know what I mean." "Most people say the same thing, but none the less I hope you are not disenchanted." "Disenchanted! My dear sir, it would be shocking ingratitude to find fault with anything in this place, especially as I can't remember ever contributing anything to its funds. Of course, that omission will have to be rectified now we can talk about that to-morrow. What I want you to be so good to do at present is, to send a messenger to 15, Mortgramit Square, and tell my valet to come here. Manage it so that no alarm is created, and nobody else comes with him. My wife and family do not arrive home till to-morrow night; and there is no need of acquainting anyone else with the accident." "Except that it is in the *Morning Post* this morning, and other daily papers." "Confound the *Morning Post*. Who put it in?" "I don't know; reporters are always prowling about, and picking up news." "Well, you'll have to bear the brunt. I am not going to see anyone to-day or to-morrow till I go home, so you must send them away. Confound the *Post*, to alarm my friends like that! I won't take it in any more." "People are hard to please," said Sister Agatha, smiling. "Here, yesterday, in this ward, a patient vowed he wouldn't take in *Lloyd's* any more, because his accident wasn't reported; and to-day another vows he won't take in the *Post* any more, because his accident is reported. It must be rather difficult for the Press to please everybody." They all laughed at this, and Dudgeon as good-humouredly as the rest. Observing then that Dyer was dressing, the surgeon having advised him to get up, Dudgeon asked Sister Agatha to tell him to come to him.

MASTER AND MAN.

"Well, my man," commenced Dudgeon, your face is familiar to me? Where were you employed in my works?" "In the fitting shop; my father, John Dyer, was there as leading hand, twenty years before me." "I remember him well. A thoroughly honest man, who did his work well down to the day of his death. And you are his son, eh? Well, and how did you meet with your accident?" At the end of Dyer's narrative, Dudgeon said, "I had heard they were upsetting the Works and discharging the old hands without mercy, and had come back to set masters to rights. I was to have paid the Works a first visit this morning. Being the largest shareholder, besides a director, I have still a voice in the concern, and when I get well I will see what can be done for you. A man who has worked all his life for a firm, as well as his father, has a claim for consideration which a master cannot ignore if a company can, particularly if he loses his eye at his work. So set your mind at rest, the future, and tell me how they have treated you in the hospital." "Me? They've treated me well enough. It's you, sir, I'm afraid they haven't treated with enough distinction. The fact is, they don't realise who you are." "Don't they?" said Dudgeon, good-humouredly, amused at the mechanic's anxiety on his behalf. "Considering the shabby way I treated them when I was well, I think they have heaped coals of fire upon my head sufficiently. To introduce distinctions would be to disorganise the ward. Observe how smoothly everything works in this place. All these poor fellows are more in want of attention than myself. I am leaving to-morrow. To me nothing is more pleasing than to see that social equality prevails in a ward, and that suffering is the only distinction that invites additional deference."

A REGULAR PIECE OF ENGINEERING.

Disabused of his idea that a slight had been cast upon Dudgeon, Dyer the mechanic launched out in praises of the institution. "Everything is clean and sweet, and seems to go like clockwork. They bring a man in dreadfully injured; the surgeon takes a sight at him, sir, as you or I would at a bit of iron, and then they all go to work washing and cleaning, coiling him up here, and padding him there, and then they fix his limbs in iron frames or wooden splints, and when at last they stow him under the sheets he's a regular piece of engineering. They take in, on an average, twenty-four accidents a day, Sunday and week-day, all the year round, and three of those are broken bones that need setting. Sometimes, the accidents mount up to sixty a day, and on a frosty night as many as nine broken legs will be brought into the place between midnight and six in the morning. Down below, I heard a man say, they've got a cellar chock-full of splints, and they order them in, sir, by the hundred."

DUDGEON AND DYER INSPECT THE WARD.

The next morning both Dudgeon and Dyer were up betimes, and, after the surgeon's inspection, prepared to leave the ward. While waiting for the House-Governor to arrive to show them over the building, he having willingly consented the night before, the two made a more thorough inspection of the ward, Sister Agatha acting as guide. There were the different kinds of beds for mitigating the rigour of lying long in one posture; the rests to ease the back or support the feet; the surgical apparatus for severe fractures; the mirrors at the back of the beds on the dark side of the ward to reflect the light on the patient's book or newspaper while reading; the surgical table on noiseless wheels, ready to be quietly rolled to any bedside while dressing or redressing a wound or a fracture; the stores of antiseptic appliances; and the special utensils devised for promoting the patient's comfort, and tiding him over periods of helplessness. Then there were the horizontal flues to point out, sucking away the vitiated atmosphere, and the ventilating apparatus drawing in and warming the fresh air; then the surgeon's druggery—like a miniature doctor's shop—to describe; then the lobby, with its blazing fire and steaming kettle, its huge white table for distributing the patients' food; its rows of plates and dishes, and cheerful array of crockery on the walls; the scullery at the side, with the scullery-maids hard at work; the lifts to bring the food from the kitchen to the ward, and the drugs to the surgeon; and outside the ward the shoot to carry away, at a stroke, all the dirty linen placed in it by the probationers. Finally, in a corner of the ward was the Sister's day-room—quite a little bower of elegance and beauty; no waste of hospital funds on grand and imposing furniture, but an individual lavishing of occasional leisure moments on a thousand and one trifles, which had converted the little square compartment composing the sister's room into a most charming retreat.

A TRIUMPH OF HOSPITAL PROGRESS.

Dudgeon was still making some complimentary remarks about Sister Agatha's sanctum, when the House-Governor appeared at the door. For forty years, he told Dudgeon and Dyer, as they walked away along the corridor, he had lived inside the hospital—first as assistant-secretary, then as secretary, and finally (for fifteen years) in charge of its present duties. He was a man of broad and enlightened views, and to improve his own organisation had directed so much attention to the arrangement and [illegible] of other hospitals that he was quite a mine of knowledge on the subject. While taking them through two or three more of the surgical wards, all more or less [illegible] plans as the Roderick, he had [illegible] saving of life in hospitals which had been brought [illegible]

the antiseptic methods of a great Professor of Surgery. "When I came here first the average mortality from the amputation cases was 30 per cent.—in some hospitals it was 40,—in spite of all the care and skill we could command at that time. Things were no better when I became House-Governor fifteen years ago. Then came the Professor, with his wonderful ideas of the germ theory of disease, and his ingenious methods of securing the absolute purity of the surfaces of wounds. The moment we adopted his system the mortality began to decrease, and some of the hospitals brought it down last year to 3 per cent.

HEROES AT HOME AS WELL AS ABROAD.

"It seems to me," said Dudgeon, when the House-Governor had finished dilating on the revolution accomplished by this great Professor of Surgery, and the hundreds of thousands of lives saved throughout the world since the hospitals adopted the system, "that a little of the raving bestowed upon the French *savant* might be worthily bestowed at home." "Quite so, and without any prejudice to the Frenchman, whom we can all admire just the same. In 1884 the Queen made the Professor a baronet for the good his discoveries had done, but isn't it a proof of the general lack of appreciation of medical science in this country, that he should not have been elevated at a stroke to the peerage? If ever you come in contact with those who have anything to do with the bestowing of titles" (addressing Dudgeon), "I hope you may have an opportunity of asking this question—Oughtn't a man who by study and hard work saves a hundred thousand lives by a great discovery, to have as much claim to a peerage as a man who by a great campaign kills half as many more?"

THE MEDICAL WARDS.

"Well, now you've seen enough of the surgical wards," he continued, as they quitted the fourth. "Let me now show you the medical ones. There are no essential differences between the two; the arrangements are exactly the same, but you will at once detect the different aspect of the patients. In the surgical wards there is not so much deathly paleness, because, apart from their wounds, the patients are healthy enough when they are brought here." Beyond this Dudgeon and Dyer saw little to note, and having passed through a couple of the men's wards, they proceeded to visit the women's, which were arranged exactly the same, and possessed similar characteristics as to roominess, brightness, and cheerfulness. Everywhere they found the print-dressed, aproned nurses and probationers busily tending the patients, the Sister, scarcely differing from them in attire, directing everything unobtrusively; and everywhere the same easy-working system, indicating the smoothness that comes from constant practice, coupled with careful organisation of details—everywhere an utter absence of officialism, and yet the constant presence of a kindly discipline.

THE CANCER WARD.

"Before going downstairs to the basement, there is one special department I should like to show you," said the House-Governor, "it is specially devoted to cases of cancer. The disease, when it reaches a certain stage, is practically incurable, and for want of room the hospitals have to reject incurable cases. We, however, differ from the rest in having three wards set apart for the reception of these incurable cases, with beds for thirty-five female patients. Twenty years ago the sum of £4000 was given anonymously to fit up a ward, and two other persons have helped to establish two more since. We take the poor creatures in, and we keep them till they die."[2] "Is that usually long?" asked Dudgeon. "Roughly, a year or two; though some remain years in the refuge. Their diet is quite unlimited; anything the physician may order to tempt their appetite, or to alleviate their pain, is obtained at once without question. If we cannot cure, we do our utmost to reduce the pain to a minimum."

A SCENE OF HUMAN MISERY.

Dudgeon was painfully impressed by the refuge. The wards were bright, and arranged the same as the rest, but being small and connected with one another, and containing chairs and tables and couches, as well as the regulation bed, the place had more the aspect of a home. Some of the inmates were up, and reading or sewing; some were sitting in bed; some were buried in their pillows—bandaged arms, or breasts, or the puffy condition of the lower part of the counterpane indicating where the disease had attacked the body. But, except in one or two cases, there were traces of recent or present pain on the pale faces of the women, which Dudgeon could not drive from his memory for many a day; and one poor creature, the whole of whose head and face was bandaged, and who lay back in bed like a whitened mummy, so shocked his sensibilities that he hurried out of the place, and begged the House-Governor to kindly show him no more such sights. "It makes me ill to see such misery."

WILL YOU HELP TO MITIGATE IT?

"Ah," said the House-Governor. "But what about us, who have this anguish brought to our doors every day, and have to send it away unrelieved because our funds are so limited? That is far more shocking. These thirty-five patients are only a sample of the incurable cancer cases of the metropolis. Imagine hundreds of others unrelieved in squalid homes! We have not a single bed to spare for men with cancers." "It is dreadful—really too dreadful. Can't they find a cure for the disease?" "Medical research is doing its utmost, and in this refuge the physicians are always studying and striving to discover a cure. Here you will see the interest the rich have in generously supporting the hospital. Isolated cases in a West-end square cannot have the research brought to bear upon them that is possible in a cancer ward full of poor people, and it may be that in this poor people's ward the discovery may be gradually elaborated which shall save the life of the richest man, or sooth the anguish of his wife and daughter. I hope, sir, you won't think I am talking *at* you, who are rich, and that I mean to pounce on your purse directly; but I want you rich people, as well as this good man here, who represents the working masses, to take the hospital on its fair merits, and not make it merely a question of charity to give to its funds. I like our chaplain for that; when he gets into the pulpit to preach a hospital sermon, he always tells the people that it is not charity but self-interest that should impel them to be liberal subscribers."

IS THIS NOT TRUE?

"I begin to think," said Dudgeon, "that there exists a good deal of misconception about hospitals. The poor think the pounds of the rich keep them going, and the rich think the pence of the poor keep them going, and between the two the hospitals run short of funds and have a bad time of it." By this time they had reached a door with the inscription "Obstetric Ward." "This is the section," observed the House-Governor, stopping, "devoted to the diseases incidental to women. There was nothing very special to note in the Obstetric ward; and, having briefly pointed out the kitchen and lavatory and druggery attached, the House-Governor paused before a separate room containing a couple of beds. "Ovariotomy cases," he observed to Dudgeon, who laconically translated his meaning to Dyer in the plainer word "tumours." "Here is another triumph of surgery," he continued, as he led them along a short corridor to a large light room with an operating bed in the middle, extensive lavatory arrangements against the wall, and a variety of cases evidently containing surgical instruments and appliances.

THE TRIUMPHS OF OVARIOTOMY.

"This is the operating theatre," said the House-Governor. "We are having it thoroughly purified after an ovariotomy case. Now, when I first came here, and for many years after, ovariotomy almost invariably ended in death. Sometimes we succeeded, but we mostly failed; and the majority of women preferred to live a little longer and die of the disease, rather than to run the risk of an operation, with the odds against them." "My poor mother died of that," observed Dudgeon. "We had the advice of the most famous physicians of the day, but, as you say, the odds were so great that she preferred putting it off until the tumour killed her." "Then you know all about the work of a late President of the College of Surgeons?" said the House-Governor. "I've heard of him by name, and met him once at a dinner; but beyond that he is a great surgeon, I can't say I know anything particular about him." "Then you must listen to this, because it will show you how a great cure may come out of a poor little hospital."

A GREAT CURE OUT OF A POOR LITTLE HOSPITAL.

"Thirty years ago this surgeon became associated with two or three other doctors in developing a Woman's Free Hospital, an institution started in a small way for the treat-

[2] This Cancer Establishment is a special feature of the Middlesex Hospital.

Digitized by Google

ment of the ordinary diseases of women and children, but which had broken down and was hardly worth any physician belonging to. Among the women who came were some with these huge internal tumours, and this gentleman, distressed at having to send them away, begged his colleagues to let him receive some ovarian cases. He was convinced that by improved methods the body could be opened, and the tumours removed with greater success than was conceived to be possible at the time. At first they would not hear of it. A few fatal cases would ruin the hospital. The consulting physician was so angry at the idea that he even denounced it in public. Then the coroner sent in word to say that if ovariotomy were practised he should hold an inquest on every fatal case. So the surgeon I have named, you see, was in a regular predicament. He was opposed in the hospital for once—it is not often that is the case,—he was opposed outside, and he would have been ruined professionally if he had failed. Still there were these poor women beseeching him for aid, or, like your poor mother, dying a lingering death after years of discomfort, and he decided to risk everything and save them."

HE DECIDES TO SAVE THEM.

"Bravo!" exclaimed Dyer, quite excited. "In 1858," continued the House-Governor, "they agreed to let him try his hand with three. He succeeded in all. Then he succeeded again and again, and that wretched little Woman's Hospital became for the moment the most famous in London, and the training school of all the world. Now, look at the operation. The patient has to be placed on this bed and chloroformed, and then, with the utmost tenderness and decency, the body is cut open, the tumour and ovary cut right out, and then the body is sewn up again. Working as hard as the operator can, the operation takes half an hour, sometimes almost an hour, and then the patient has to be very carefully conveyed back to the ward, and to receive the most assiduous nursing for a couple of months."

WHO WOULD NOT HELP TO PROMOTE SUCH TRIUMPHS?

"And is the cure perfect?" inquired Dudgeon. "Invariably. A patient arrives too unwieldy to walk, and miserably ill; she leaves so thoroughly cured that, except in rare cases, where there may be, say, cancer or some other disease tacked on to it, the probability is that she may never be attacked by a tumour any more. A very large number of cases come from the country. We had one the other day. A woman came from the north so bulky from a tumour that she could not sit during the railway journey, but had to remain on her knees. It was a very bad case, but we cured her. When she went back, her friends and neighbours, who never thought to see her again, and wouldn't believe she was cured, were indeed delighted." "And my poor mother," exclaimed Dudgeon, "with all her wealth, had to perish!" "Do you find them very grateful?" asked Dyer. "Grateful," said the House-Governor, with moistened eyes. "You can't estimate what gratitude is until you see some poor woman, the mother of a family she doesn't want to die and leave, come to this place thinking herself doomed, and leaving here with a long and happy life before her. Of course," he added, "success was not won at a stroke—few successes are. At the outset about one in four died, then one in five, then one in seven, ten, fifteen, and now they have reduced it to nearly one in twenty. One hospital is now devoted almost wholly to ovariotomy, and last year there were only six cases of death out of a hundred. They've done there thirty-eight consecutive cases without a single death. Isn't that grand?"

A MORAL FOR US ALL.

"So your moral is," remarked Dudgeon, "that out of that hospital, to which perhaps my poor mother may have given a trifling donation or two, there sprang a cure which might have saved her life had she lived a little longer?" "Quite so. The hospital cry is, 'Equip me with more funds, that I may be able to devise methods of curing others to-day, which may save your own life to-morrow.' Ovariotomy is a heavy drag on the hospital. Every case costs us at least £10. The usual private fee of a skilled ovariotomist of repute is 100 guineas. If reduced to meet a [illegible] to ten or twenty guineas, the cost of nursing [illegible], and good nursing is essential, that [illegible] people, the [illegible] as you [illegible] it, [illegible] ious. I have [illegible] a fashionable surgeon, after spending all day attending patients in the West-end, come down here at night, and spend the whole night in the ward, to watch, without a penny of payment, over the wife of a costermonger."

THE HOSPITAL KITCHEN.

"But," he exclaimed, springing to his feet, "I have talked enough about this operation, and we'll go down now to the kitchen. We shall just catch them serving the dinner up." Descending to the basement by a lift used for conveying the patients to the different stories, Dudgeon and Dyer followed the House-Governor along a passage to a huge room, with walls and ceiling covered with white tiles to admit of ready cleansing. "All the cooking is done by gas and steam," observed the House-Governor, "and it saves an immense amount of labour. The system is this. Every afternoon the sisters collect the diet sheets of each patient, and transmit them to the steward's office, where the clerks make out a gross list of the food required, and order it in. In the morning supplementary lists are made of any fresh diets ordered during the night, and then the cook goes to work. A few hands are drafted in, who get the food ready; and a few porters are now coming in to help transmit it to the wards; but, apart from this, all the work in the kitchen is done by one cook, and a kitchen and scullery maid. It is now half-past eleven, and the food is going up into the wards. We send it in the gross, and in each ward it is divided and distributed in the lobby. On this table are trays of fish, plaice, and soles beautifully brown; here is boiled plaice; and there are the hot water boxes to hold the food. The cook refers to his list: so many diets of plaice to Roderick ward; he puts them in the box, shuts down the lid, the porter puts it on a trolly, and off it goes with other boxes to the lift. In a minute or two it will reach the ward as hot as it left here, and the probationers and nurses will be ready to serve it out to the patients."

SERVING UP THE DINNERS.

"To-day is leg-of-mutton day. Forty or more legs of mutton are fixed inside the iron frame of this trolly, lowered by a lift into a safe, whence, after a couple of hours, they return baked a beautiful brown colour. On the table a porter places the lot, and the cook weighs so much for each ward, cutting up a leg now and again to make up the requisite quantity. Here are the trays of chops—we cook seventy or eighty every day. There in that steam chest are nets of potatoes, each containing the quantity ordered for each ward. Those ovens beyond are full of milk puddings—sago, tapioca, and so forth. The dishes are marked, so as to enable the pudding to be easily carved into diets. The coppers at the side are full of beef-tea. One sort consists of 8 oz. of beef to the pint, another 16 oz., and we have also some extract for special cases, 3 lb. to the pint. Every pint of the last costs half-a-crown." "You must consume a tremendous amount of food every year," said Dyer. "Surprising," answered the House-Governor. "We spent last year £1200 on bread, £2700 on milk, and £6000 on meat. We used about a quarter of a million of eggs, costing nearly £1000. Butter and cheese cost another £1000; vegetables £700, grocery £550, and fish £570. Altogether, including gas and firing, the kitchen cost us nearly £15,000." From the kitchen the party made their way into the laundry, where, amidst the steam, the House-Governor explained the process by which the linen arriving by the shoots from the wards was soaked, steamed, rinsed, and wrung by machinery, and then passed on to capacious drying ovens adjoining the ironing room. "Every week we wash from 5000 to 7000 sheets, and 300 or 400 blankets," he observed; "and from that coal-cellar there, at the end of the passage, about seven tons of coal have to be carried and distributed by porters in the various wards every winter's morning. It's a nasty job, taking them over two hours; but open fires are so wholesome and cheerful, that we're bound to have them in all the wards."

£5000 A YEAR ON MEDICINE.

Ascending to the ground floor, the House-Governor took them into the Dispensary, which seemed like a series of chemists' shops rolled into one, and every bottle and drug case proportionately amplified. "This dispensary costs us, without wages, over £5000 a year," said he. "Nearly £2000 is spent on drugs and chemicals, £760 on spirits of [illegible], £400 on glass and earthenware, £460 on scientific [illegible], £350 on ice, lemon-juice, soda-water, and similar [illegible]. We use a ton and a quarter of ice a day. And every [illegible] three trollies of drugs have to be issued from [illegible]

Digitized by Google

the use of the patients. That doesn't include," he continued, while showing them a large room where a couple of men were making tinctures, "the money—£2700 a year—we spend on things for the surgeons. For instance, we spend over £10 a week on calico and flannel, another £10 a week on wool and tow, nearly another £10 on plaster, while surgical instruments cost us £500 a year, lint £270, antiseptic appliances £250, linseed-meal £100, and lard £50. The smallest item nowadays is leeches," he said, pointing to a large glass jar containing a hundred. "When I came here forty years ago we used to spend nearly £500 a year on leeches. Last year we spent only 50*s*."

WHERE REAL BENEVOLENCE COMES IN.

Outside the Dispensary were the waiting-halls for the out-patients, very many of whom, men, women, and children, were sitting on rows of seats like the pit audience of a theatre, waiting their turn to proceed in batches to a series of doors admitting them into the consulting-rooms. Passing on their way a large coffee bar, where a man was busy at work in a shrine of cups and saucers, and cakes and sweets, vending at a penny a cup coffee, tea, cocoa, or milk to exhausted patients, the House-Governor paused. "This is a new feature," he said, "now on its trial. Many patients come a great distance and have sometimes to wait a long while; they get fagged and tired, and a cup of tea not only refreshes them and keeps them in a good humour, but it prevents the dram bottle being brought into the place. The sweets are added to keep the youngsters quiet." A little further on he stopped again before a beautiful fountain, in Doulton's best style, inserted into the wall, where several patients were drinking. "If the Chaplain were here," he remarked to Dudgeon, "he would say, 'This is where real benevolence comes in.' It is a man's interest and duty to give regularly a money donation to the hospital, but he is not morally bound to put up a drinking-fountain in a waiting-hall to be a benefit to out-patients. This is a free gift from a gentleman in memory of a little child. It was he who fitted up the coffee bar for us. Considering that nearly 70,000 out-patients attend here every year, and that their attendances amount to hundreds of thousands of times, I think you will agree with me that it must be a boon to the people. The out-patients come in such shoals," he continued later on, "that we have had to adopt a sort of weeding process. We refuse no one ill who comes with a letter a first consultation, and we admit every surgical case whether the sufferer have a letter or not; but when we find that a patient really can pay for a good doctor, we are forced by the swarms of really destitute people to ask the applicant to do so.

A HOSPITAL CHEAT.

"A typical case occurred a short time ago. A man from the Transvaal appeared at an Ophthalmic Hospital in the City as an out-patient, and said he was very poor, having lost all his property in the war. On the strength of this he was admitted as an in-patient to undergo an operation, and after the operation fell ill with an internal disease, and was brought here and died. When his clothes were examined it was found he had £6000 in the bank, and his conscience having pricked him, he had sent, unknown to us, for a lawyer to make a will, and left £500 to the Eye Hospital. We exercise the greatest tact in weeding suspected cases, and the patients often benefit by the inquiry, as they get additional help from the Samaritan Fund." "What is that fund?" inquired Dyer; "I've often heard it mentioned since I came here." "It is a fund kept apart from the regular hospital funds, and is managed by a separate committee; it supplies artificial limbs and mechanical aids to poor people, sends patients to convalescent homes, and makes small grants of money to poor persons on leaving the hospital. We make it our boast that we never let anyone leave the hospital absolutely penniless if we can help it. A few shillings may be a god-send to a poor man, who on leaving the hospital may perhaps get nothing to eat till he earns it, and will tide him over starvation. As for the convalescent homes, most people know something about them. We send 800 patients a year to these homes, and support them while there; but the public don't know what the hospital does in giving away surgical appliances."

SURGICAL AID TO THE POOR.

"Two of the surgical societies give away each about 5000 appliances a year, and between them have distributed 100,000 artificial limbs, bands, trusses, elastic stockings, and other similar things since they were established. The Hospital Sunday Fund spent last year £1600 on this object. If you can only realise that one person out of every ten in the metropolis has to make use of some surgical appliance or other, you can appreciate the benefit conferred by the free distribution of these appliances. Poor persons, who would otherwise be a burden to the public, are enabled to earn a living and become useful members of society. Then the Samaritan Fund enables us to give free dinners to some of the out-patients who appear to be more in want of nourishment than medicine, and also milk to starving infants. The Samaritan Fund is thus one of the most useful branches of any hospital." Taking his watch then out of his pocket, he added, "You have been too long on your feet now to go over the nursing home in the next wing, and the medical college over yonder, which you can see from this window. Hundreds of students are educated in the college, and having obtained a regular training in the hospital, go forth to become family doctors or famous physicians. And not only does the hospital afford the best possible training to the family doctor, but it now supplies nearly all the nurses. Hundreds are trained in the hospital, and after acquiring experience in the ward, and systematic medical instruction, go forth with their certificate to assist the family doctor. Now for the Children's Ward, and we shall have seen most of the General Hospital.

IN THE CHILDREN'S WARD.

"My favourite ward," said the House-Governor, ushering in Dudgeon and Dyer on their arrival. "Here are forty beds full of little ones, all surgical cases. In some hospitals the children are stowed in cots among the adults, but we are able to keep them by themselves, which is much better. In an adults' ward they are apt to disturb the grown-up patients, and they are never so happy isolated as when put by themselves in a ward like this. Here are twenty cots on each side of the room, with stands fixed over them for the children to put their toys on, and beyond are other wards devoted to more surgical cases, and then medical wards—all in the same style." Evidently the House-Governor was a favourite, for lots of little heads peeped above the cots when his voice was heard, and a youngster shouted out lustily from the end of the ward—"Daddy—I say, daddy, look here!" "Keep quiet, you rogue, till I come," replied the House-Governor, good-naturedly. The boy continuing to beg him to come, the party walked down the ward to his cot. "A boy of nine," observed the House-Governor as they went along, "who has been here two months suffering from a stiff knee. He is nearly well, and we're going to send him to a convalescent home at Eastbourne next week." "Look here, look here!" shouted the boy, holding out a book—one of those gorgeously-bound volumes which Nelson and Sons issue for presents and prizes for two or three shillings. "Look here—'The Swiss Family Robinson,' full of pictures, which a kind lady has just given me. Look at all the gold upon the cover. You shall have it to read, daddy, when I have done." "Go on, you little rogue," said the House-Governor, poking him good-humouredly in the ribs, but evidently quite as well pleased as the boy.

THE KIND OF BOOK FOR A HOSPITAL.

Placing the book in Dudgeon's hands, he said, "That's the kind of book for a hospital. You would be astonished at the rubbish people send—old magazines, dirty and torn, and not in consecutive numbers, and then expect us to pay the carriage. We don't want rubbish, I tell them, but bright, cheerful books like these, lasting just long enough to be well read, and no longer. On sanitary grounds it doesn't do for a book to last too long in a hospital, and a bright cover excites the people's desire to read it far more than the strongest dull binding in calf." Passing then along the beds, he pointed out some of the cases to Dudgeon. "There's a new arrival," pointing to a stolid child who had been crying, but now was quiet. "Came in this morning. Fell off the kerb-stone and broke its leg. This one——ah, what, you've got a new drum; that *is* nice. This one broke his ankle in jumping off a chair. That one is a tracheotomy case. Swallowed poison, causing the throat to close, and we had to open the throat and insert a tube for him to breathe through. Nasty case; he has been here nearly a twelvemonth, but the worst is over, and the doctors think they'll save him. Hallo!" (taking up a little boy who had run up and clasped his knee). "This youngster has spent most of his life in the hospita'

Digitized by Google

He has always got some serious illness, and the moment he recovers he breaks a leg or arm, and comes in again. There—off you go" (speaking to the child). "He's leaving us to-morrow" (addressing Dudgeon again).

A WORD FOR M.P.'S.

"This one," he continued "is a lamp explosion case. The mother was turning down the wick of a cheap paraffin lamp, when it exploded and burnt the child all over." "Those beastly paraffin lamps!" exclaimed Dyer. "You may well say that," continued the House-Governor. "Every week we have to admit several people suffering from burns and explosions, and they say that nearly every week an inquest is held in London on somebody killed by them. Parliament insists upon safe lamps for the mines, but, considering that hundreds of people throughout the country are annually burnt or killed by oil lamps, why does it not insist upon safe lamps for the masses? Most of the cheap lamps might be marked, 'Certain death, or the house on fire, if upset,' and the manufacturers know it. Do you know that one-fifth of the fires in London are caused by mineral oil lamps?"

A CHILDREN'S HOSPITAL SUNDAY.

As they returned through the boys' surgical ward, they heard the boy with the stiff knee crowing afresh, and, looking round, saw the Chaplain entering with his pockets bulging out in a manner most unbecoming for a trim ecclesiastic. From these he extracted several toys and distributed them to those of the youngsters who appeared to be at all in the dumps, while the House-Governor whispered to Dudgeon, "The Chaplain's favourite walk is to the Mansion House, to pick up the cheap penny novelties that are sold in Cheapside. He'll keep the ward quiet the whole afternoon when he brings home something new and out of the common. Look at him; he's just as pleased as they are. His latest idea is to get up among Sunday school teachers a regular annual Children's Hospital Sunday. Each child might bring a toy, or a book, or a penny to the collection, and the proceeds could be divided among the children's wards of the various London hospitals. It's a splendid idea, and he hopes to persuade all the clergy to take it up before long." "You're wanted outside," said the Chaplain, coming up—"I shall be with you to lunch almost directly." "We'll see what it is" replied the House-Governor, "and then we'll go upstairs through the hospital staff's quarters to the dining-room. We officials all feed together, and after your tiring inspection I am sure you must want some luncheon."

THE HOUSE-GOVERNOR WANTED.

When they reached the outside, where convalescent patients were walking about in the small but well-kept garden, or smoking in the pavilion in the centre set aside for that purpose, they saw a cart heaped up with bird-cages, in charge of a middle-aged man in a coarse grey tweed suit. He was the bird-fancier's executor, and the dead master of the little pets having been buried the day before, he had brought his bequest to the hospital. At the back of the cart was a splendid parrot, in a brand new cage, which, as the House-Governor went down the steps, startled him by exclaiming in the most natural voice in the world, "Mind how you fall, old fellow!" "Just the very thing for the Children's Ward," said the House-Governor, in a tone of delight. "I'll take it in to them at once. No, I won't, though; the Chaplain shall do it. He deserves the treat far more than myself—a really genuine, good-hearted fellow! Stop; he mustn't have it till after luncheon, or we shan't have him at table with us. Once he gets that parrot in the ward, there'll be no getting him out of it again." Finding the man could wait for a while with the canaries and larks and linnets, the House-Governor conducted Dudgeon and Dyer into the hospital again, followed by the farewell cry of the parrot—"Oh, you naughty boys; won't I tell your mother!"

THE LUNCHEON TOGETHER.

All three, delighted and amused, then traversed a corridor terminating in an extension of the hospital devoted to the staff. Each official had his own set of rooms, and in the basement was a kitchen devoted to the whole, communicating by a lift with a room on the ground floor overlooking the garden, where they lunched in common. Here assembled and already having luncheon were the Matron, the Secretary, and the Steward, several house-surgeons and physicians—one of the former of whom had attended both Dudgeon and Dyer,—and at the end of the table the Chaplain. Taking a seat at the top, the House-Governor placed Dudgeon and Dyer one on each side of him (in spite of the protests of the latter, who did not wish to thrust himself on "such great people"), and assisted them to the cold joint and the salad on the table, apologising for the simple character of the luncheon on the grounds that he wished them to see how they all lived every day. "In front of you are jugs of milk and table-beer, and if you care for cocoa and coffee the Chaplain will help you at the other end of the table." The conversation was at first about what they thought of the hospital, and by degrees it worked round to the question of Hospital Sunday. The Secretary was very indignant at the small results achieved hitherto by the Hospital Sunday Fund. "Bearing in mind the vast population of the metropolis, £30,000 or £40,000 is a paltry amount for the largest city in the world. Last year the collection amounted to only £36,000, and it costs £50,000 to keep the General Hospital alone going. The collection in London was less than in many of the provincial cities, notwithstanding its size and wealth; and yet the London people in a general way profess to be proud of their hospitals."

HARD KNOCKS FOR THE MIDDLE CLASSES.

This led to a discussion in which, perhaps out of delicacy for the representatives of capital and labour present, the Secretary directed his denunciations chiefly against the middle classes. "We train their doctors for them, we train their nurses, we spend our money in trying to find out cures for cancer, consumption, and other diseases they all suffer from, and yet they are as lumpy as lead to our appeals for contributions. Your £10,000-a-year-man gives large donations from benevolence, and other motives we need not discuss; and your £2-a-week-man gives a trifle because his wife and children, as well as himself, are liable to attend the hospital. But what can you do with the thousands of Londoners with incomes ranging from £300 a year upwards. They can't afford large donations, and out of pride won't have small ones published in the papers, and when the Hospital Sunday people take them in hand a threepenny-piece or sixpence mostly represents a year's contributions. The middle classes, fat and apathetic, want stirring up far more than the masses."

DYER HIMSELF PERFORMS AN OPERATION ON LEAVING.

After luncheon Dyer got up from his seat and said, "I hope you will excuse me now if I leave; I'm afraid the missis may be running about trying to find me. I thank you all from the bottom of my heart for your kindness. I'm not good at speechifying, but a man can feel gratitude if he can't find words to express it." "Well, Dyer," observed Dudgeon, wishing to avoid any scene, "you must have a few days' rest to get used to your one eye, and in the meantime your pay will run on from the day you left, as before. The office will tell you when to return to your work." "Thank you, sir, for your goodness. I believe you will find I shall always work as hard with one eye as with two." "There's a promise of the honest fulfilment in that," said the Chaplain, shaking his hand heartily, and, followed by the smiles of the Matron, the mechanic left the room with the House-Governor. A few minutes afterwards the latter returned, and in an excited voice exclaimed, "What do you think? When his missis met him, he took from her a purse, and, placing it in my hand, said, 'That's for the hospital. The mates collected £9 12*s.* 4*d.* to keep me while out of work, and as I haven't been out of work, because the governor's kept me on, I want you to spend it on the poor fellows inside. I asked him to reflect—the sum was so large for a working man; but he said, 'It's not mine; it's the mates'. We workmen are not so mean as they sometimes say; and if we haven't done more for the hospital in the past, it's not, because we're stingy, but, because we don't know till we're ill, and hard up the good it does to us chaps, and the kids, and the missis. If you'd only send among us a chap that's got the gift of the gab and tell us all you've shown me this morning, you wouldn't want much tugging to haul the shillings out of our pockets."

DUDGEON RESCUED BY HIS WIFE.

Dudgeon seemed delighted at the conduct of his workman, but before he could say anything the door opened afresh, and a lady rushing in threw herself upon his unwounded shoulder, exclaiming: "My poor dear husband, to think you should have been nearly killed [illegible] to this dreadful hospital. I took [illegible]

Digitized by Google

the news was wired to us, and have come to arrange to carry you home immediately." "My dear," said Dudgeon, gravely, "consider who's here. Since I was brought here insensible on a stretcher, I have been treated with kindness I can never forget, and have seen so much goodness diffused by these dear people that I shall always take an interest in hospital work. Another day we must come together and go over the place. To-day I have tired myself enough, and I shall really be ill if I have any more excitement." Introducing then the House-Governor, the Matron, and the Chaplain to his wife, he made them promise to come and dine with him at his house in Mortgramit Square as soon as he was well, not forgetting to bring with them Sister Agatha.

A LESSON LEARNED BY CRŒSUS.

"You have shown me" he said as he quitted the room, that self-interest as well as benevolence should dictate a readier appreciation of hospital work, and you will find, I think, so far as I am concerned, without my making any rash promises, that the General Hospital has secured in me a Governor for Life." And so it had; for the same day the House-Governor received from him a cheque for £10,000, to be applied to various branches of the hospital as he thought fit, and there are rumours about now that he proposes spending ten times that sum in adding a Dudgeon Wing to it. If he does, his munificence will help to mitigate a little of the human misery of our great metropolis. Yet only a little, so vast is the misery in a city which counts its sick yearly by hundreds of thousands. The magnanimous behaviour of Dudgeon and Dyer consequently does not exhaust the good to be done, and plenty, alas, is left to be accomplished by kindly hearts and generous purses. What occurred to them may happen to you or I ere the year is out; and let us hope, therefore, that if we are carried helpless into an accident ward, we shall not have it on our conscience that, knowing what we now do of the good work the hospital does, we were shabby in our contributions at church on Hospital Sunday.

"GOD LOVETH A CHEERFUL GIVER."

THE HOSPITALS WEEK.

A PROLOGUE TO HOSPITAL SUNDAY.

The gospel to-day we would publish
Is the old one of brotherly love;
The crusade we once more would establish
Is the sympathy taught from above.
Whilst this gospel needeth no teaching
To prove that its precepts are pure,
This crusade will have cause for good preaching
To make its accomplishment sure.

In our midst there are many who rarely
(Nor even by chance nor by stealth)
May gaze on Hope's countenance fairly,
Or compass the hand-clasp of Health;
Whose eyes with much watching are aching,
And weary with weeping, and worn,
Whose hearts with long suffering are breaking,
Whose bodies with torture are torn.

Who long through the night for the morrow,
Then pine for the night-time again;
Who only find solace in sorrow,
Whose constant companion is Pain.
'Tis for these that in Health's name we greet you—
For these on whom Sickness doth frown;
'Tis for these we in Hope's name entreat you—
Whom Despair hath cast utterly down.

They are gathered and garnered together,
The weary, the weak, and the worn,
Secure from the stress of Life's weather,
And safe from its shame and its scorn.
From country, from coast, and from city,
Like sheep to a fold they have come,
In the Hospitals mercy and pity
Provide them a rest and a home.

From these Houses of Mercy and Pity
A desolate cry doth ascend,
That rings high o'er the roar of our city,
And resounds through the length of the land;
'Tis the voice of a great lamentation
From the thousands that sorrow to-day,
Whose appeal for your alms and oblations
You cannot but choose to obey.

THE HOSPITALS WEEK.

From Monday, June 21st, to Saturday, June 26th, 1886.

ITS OBJECTS ARE:—To extend the interest and support already given to the Hospitals and Medical Charities, by arousing and fixing public attention to the following facts:

(1) The pressing pecuniary necessities of these institutions; and

(2) The importance of their efficient maintenance to all classes of the community, from the highest to the lowest.

At the meetings, which will present many features of special interest, it is not proposed to make any collection, but to invite all intelligent citizens of every class to make a point of—

(*a*) Attending some place of worship on Hospital Sunday, June 27th, 1886;

(*b*) Sending a contribution direct to the Lord Mayor at the Mansion-house, or

(*c*) Placing a donation in the boxes which will be fixed outside the Mansion-house for the convenience of those who prefer to give in that way.

LIST OF THE MEETINGS.

INAUGURAL MEETING. THURSDAY, June 17th.
Mansion House, 3 P.M.

President—The Lord Mayor.
Mr. Brudenell Carter, F.R.C.S., President of the Medical Society, will deliver an oration.
Speakers—Cardinal Manning; Sir Edmund Hay Currie; Sir Spencer Wells, Bart., F.R.C.S.; Sir Risdon Bennett M.D., F.R.S.; and others.

MONDAY, 21st June.—*Lambeth Palace Library*, 3 P.M.
President—Sir Andrew Clark, Bart., M.D., F.R.S.
Speakers—Lord Sandhurst, Under-Secretary for War; Gen. Crawford Fraser, V.C., M.P.; Mr. O. V. Morgan, M.P.; Sir Hy. Peek, Bart.; Canon Erskine Clarke.

TUESDAY, 22nd June.—*The Rink Hall, Blackheath*, 8 P.M.
President—The Earl of Dartmouth.
Speakers—Baron F. de Rothschild, M.P.; Baron Henry de Worms, M.P.; Mr. Henry C. Burdett.

WEDNESDAY, 23rd June.—*Kensington Town Hall*, 3 P.M.
President—The Duke of Norfolk.
Speakers—Sir Algernon Borthwick, M.P.; The Right Hon. the Marquis of Hartington, M.P.; The Right Hon. W. H. Smith, M.P.; Sir Wm. Mac Cormac, F.R.C.S.

THURSDAY, 24th June.—*St. Andrew's Hall, Newman-street*, 8 P.M.
President—The Earl of Northbrook.
Speakers—Lord Charles Beresford, M.P.; Mr. Seager Hunt, M.P.; Mr. Bauman, M.P.; Rev. Canon Barker; Major Ross, M.P.

FRIDAY, 25th June.—*Highbury Athenæum*, 8 P.M.
President—The Duke of Westminster, K.G.
Speakers—Mr. R. Chamberlain, M.P.; Mr. Ince, Q.C.; Mr. Waddy, Q.C.; Mr. Bartley, M.P.; Mr. Cowley Lambert; Dr. Buchanan; Sir Dyce Duckworth, M.D.; Mr. Murdock, M.P.; Mr. Bigwood, M.P.

SATURDAY, 26th June—*Stratford Town Hall*, 4 P.M.
President—H.R.H. the Duke of Cambridge.
Speaker—The Marquis of Salisbury, K.G.

*** The meetings will all be free and open, and no tickets of admission will be required.

NOTICES TO THE CLERGY AND MINISTERS OF RELIGION.

The Proprietors of THE LANCET will send free copies of this Special Supplement on application to any clergyman or minister of religion who may require them for distribution amongst the more wealthy members of their congregations.

It is requested that an early notification may be sent to the Editor of THE LANCET, 423, Strand, W.C., of all special sermons to be preached in aid of the Hospitals at any of the services on Hospital Sunday, June 27th. All such notices should reach this Office not later than Wednesday, June 23rd, with the subject of each discourse, in time to appear in the second Special Supplement, which will be issued with THE LANCET of Saturday, June 26th.

A third Supplement, containing a report of the special sermons preached on Hospital Sunday, will be published with THE LANCET of July 3rd, and all extracts of sermons intended for publication should reach the Editor not later than Tuesday, June 29th.

SUMMARY.

It will be seen from the following summary that the hospitals and medical charities of London, during the twelve months ending Dec. 31st, 1885, relieved upwards of 1,000,000 patients at a total cost of £491,634. The total income from all sources was only a little over £451,000, so that there was an actual deficiency on the year's working of upwards of £40,000.

AN APPEAL ON THE FACTS.

OUT of four million inhabitants it will be seen that upwards of one million *directly* received relief from the hospitals during this year alone. Who shall estimate the amount of benefit which the hospitals have *indirectly* given to Londoners in addition, through the medical profession and skilled nurses, whom the hospitals have trained to minister to those who can afford to be treated at their own homes in the hour of sickness? Towards defraying the cost to the hospitals of directly relieving in a single year this grand total of human misery, the available funds were inadequate to the extent of £40,000, a deficiency which would have been nearly doubled except for the money at present subscribed on Hospital Sunday. We ask the wealthy, the thoughtful, and the generous to study the above figures. They will show to all how each charity does its work, and what is the principle upon which that work is carried on.

Some people hold, with Mr. Spurgeon, that the managers of a charity should never be waiters upon Providence, but that funds should be collected and placed in the bank before orders are given for the work to be undertaken. This list will be found to contain institutions which have managed to make both ends meet and a little over, so that Mr. Spurgeon's principles are well represented. Unfortunately, however, it is not always possible to conduct a hospital on such business-like principles, or many sick and suffering folk would fare badly indeed at times. To be of the greatest utility, a hospital has often to be placed in the midst of a dense and indigent population, who have not the means of supporting it adequately, and the managers have therefore to appeal to the charitable who live in the wealthier parts of the town. In such circumstances it necessarily happens that the hospital is in a chronic state of impecuniosity, and many such institutions will be found with the others given here. It is not too much to say the very varying condition of the hospitals of London revealed in these Tables must include every conceivable variety of circumstance, and so be calculated to meet the views of every group of philanthropists. This fact, coupled with the remembrance that the crusade to be conducted throughout the Hospitals Week, as a prologue to Hospital Sunday, is a united movement in favour of all the hospitals, should call forth an amount of enthusiasm worthy of so great a cause, and the pressing pecuniary needs of a class of charities the efficient maintenance of which is a matter of vital importance to all classes of the community. At least £80,000 is needed. Shall it not be forthcoming? Will the flowers of so fragrant a garden be neglected by men and women who have means? The receipts on Hospital Sunday will afford the best answer. In London to-day

> The charities which soothe, and heal, and bless,
> Lie scattered at the feet of men like flowers.

Who will not gather a button-hole at least, if a bouquet be indeed beyond their resources?

Clinical Lectures ON DISEASES OF THE EYE.

Delivered at the Nottingham and Midland Eye Infirmary.

By CHARLES BELL TAYLOR, M.D., F.R.C.S.,
SURGEON TO THE INFIRMARY.

LECTURE III.

ON SQUINT.

GENTLEMEN,—A short time ago a gentleman holding an important official position in a neighbouring county consulted me on account of failing vision in the left eye. The eye of which he complained occupied its normal position in the orbit, but the right presented exactly the appearance depicted in Fig. 3. I said, "Why don't you have your right eye put straight?" "Because," he replied, "I have during the last twenty years on separate occasions consulted three eminent surgeons, and they each tell me that in order to restore the position of the eyeball it would be necessary to divide the external muscle, and that such division would not only aggravate the existing protrusion, but might even let the eye out of the socket altogether." I explained to him that it would not be necessary to interfere with the external muscle at all, and that so far from increasing the protrusion, the replacement of the eyeball would improve vision and restore his good looks.

FIG. 1.

Before operation.

You have often seen me perform this operation, which admits of rapid execution, and may be undertaken without anæsthetics. I hook up the tendon of the internal rectus muscle and divide all its connexions with the eyeball, pull it well forward, and by two horizontal incisions made with scissors convert it into a narrow strip. I then transfix the base of this strip as far back in the orbit as possible with a large curved needle connected with a thread armed at both ends. Before drawing the thread through I cut off as much of the tendon as may be considered necessary, and with the remaining needle pierce a small portion of the sclerotic about the site of the insertion of the inferior rectus tendon. Having thus obtained complete control of the eyeball, I turn it inwards to any required extent by simply tying the thread. This method of operation is quite as successful in result as any operation can be; it is scarcely more formidable than the ordinary tenotomy for internal squint; the external rectus is untouched, and only one suture is usually required. Here is a patient operated upon some years ago, who attends to-night in order that you may appreciate the permanence of the results attained. He is, as some of you may remember, one of the subjects whose photograph was reproduced in the *Practitioner* of December, 1883. (Figs. 1 and 2.)

Cases of external strabismus vary in degree from mere insufficiency of the internal recti muscles to such aggravated examples as those here depicted, and they all admit of relief by operation. Simple tenotomy of the external rectus will suffice to neutralise insufficiency of the internal recti, but such an operation ought never to be undertaken unless the external rectus is sufficiently strong to overcome a prism of 10°; slighter cases may be relieved by appropriate prisms worn with the base inwards, or by decentred glasses, which have a similar effect. Like myopia—a condition with which it is most frequently associated—the defect may be congenital, or merely a consequence of imperfect vision from any cause; the eye wandering outwards for want of visual guidance. The worst cases are observed in patients suffering from paralysis of the third nerve, or are caused by accident or unskilful operations for internal squint. If the deformity is slight, but still not such as would be relieved by simple tenotomy, I divide the external rectus subconjunctivally and insert a suture just over the tendon of the inferior rectus muscle; having thus secured control of the eyeball, I turn it inwards by attaching the suture to the internal canthus; this forced inversion is maintained for some days, and the external rectus, being compelled to attach itself further back on the eyeball, loses its power of abnormally diverting the globe. In medium cases I divide the internal and external recti muscles subconjunctivally, and secure inversion as before; in this way the internal rectus is brought forward and the external rectus thrown back. The advantage of these latter methods is that

FIG. 2.

After operation.

there is no open wound, no risk, and very little inconvenience to the patient. If the deformity is caused by paralysis of the third nerve, it will usually yield to medicine, volitional exercises, or the electric current; but after ordinary treatment the cure may often be expedited by advancement of the affected muscle, or tenotomy of the antagonist or associate muscle. One of the patients upon whom I am about to operate to-night is a collier suffering from slight squint, the remains of a paralytic affection of the third nerve, which six months ago caused extreme divergence of the right eye. Another who will also need attention is a railway official, whose left eye protrudes and diverges to a frightful extent, owing to laceration and separation of the internal rectus, the result of a malicious thrust with a stick. This is what happens when patients are unskilfully operated on for internal squint: the belly of the muscle is divided, the capsule of Tenon is lacerated, and,

Digitized by Google

the rectus falls back so far in the orbit that it is unable to reattach itself to the globe. Here are two photographs of a patient, before and after treatment, on whom I operated some time ago for extreme divergence occasioned in this way. (Figs. 3 and 4).

To avoid such disastrous results as are depicted in Fig. 3 we must, in operating for internal squint, be careful to divide the tendon only, not to do too much at once, and depend upon tenotomy of the associate muscle for increased effect when necessary. Von Graefe, whose practice I had an opportunity of studying when in Berlin, used, with this end in view, to make an incision directly over the insertion of the internal rectus, expose the tendon, and divide it on a small hook, as shown in Fig. 5. This procedure involves either an open wound or a suture; and in order to obviate the inconvenience attending the insertion and subsequent removal of a thread, I have been in the habit of making an incision directly over the lower border of the internal rectus muscle, inserting a small hook beneath

FIG. 3.

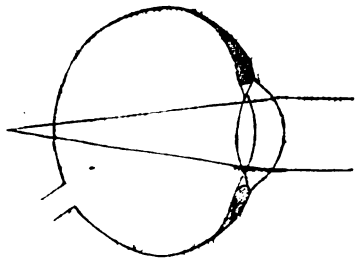
the tendon, causing the extremity of the hook to project beyond its upper border, and cutting on the point, thus dividing the attachment of the tendon under the small bridge of conjunctiva which is allowed to remain; in this way we have a small puncture and counter-puncture, but no open wound, and the tendon, and the tendon only, is divided as readily as though it had been laid bare. If after operation, in spite of all our care, there should appear to be a tendency to eversion, I limit the effect by a suture, catching up the tendon and adjacent tissues, and stitching them to the conjunctiva and subconjunctival tissues at the inner edge of the cornea. When the squint is slight, not more than two lines, you may succeed by operating on one eye only; but the graver varieties, unless when one eye has become completely amblyopic, require the division of both tendons. The first effect of the operation is somewhat diminished when the tendon becomes reattached to the eyeball, and is afterwards, in the course of a few weeks or months, slightly increased, owing to the action of the opponent muscle, which is now enabled to exert a greater influence upon the globe, so that a slight residual convergence will often disappear. This desirable end is much more certainly attained by the use of spectacles, which correct any error of refraction. If, on the other hand, we find that the ultimate result is a tendency to eversion, this malposition may be corrected by withholding glasses, so that the necessity for convergence accompanying increased accommodation may help to restore parallelism of the globes. If in the course of time we find that, in spite of all that has been done, one or both eyes are turned slightly outwards, they may readily be put straight by simply dividing both external recti muscles subconjunctivally.

Here is a small boy, six years of age, on whom you shall see me operate by tenotomy of the internal rectus in the way to be presently described. He is suffering from the most common form of squint—strabismus convergens concomitans. His mother thinks he caught the affection from a playmate, but he really began to squint two years ago, because he then began to learn to read; such patients squint as soon as the eyes are used for near objects, and the more they are thus used the worse does the defect become. You will notice in this case that the child shows a slight tendency to turn the left eye inwards at times, but the right is much the worst; and we have ascertained that the sight of this eye is the weaker of the two, although he can still decipher large print with it. I have ascertained, by making a dot upon the lower lid exactly in the middle and another in continuation with a vertical line drawn through the centre of the right cornea in its abnormal position, that the extent of the deviation is exactly three and a half lines. If I now close the left eye and direct the patient to look straight with the squinting one, it assumes its normal position; but on raising my hand we find that the left eye has become the squinting one, and, moreover, that the extent of the deviation is exactly the same as that of the right eye. It is as though the two eyes were connected by a cord

FIG. 4.

that was too short to permit them both to look straight at once, and that whatever was taken on one side had to be given from the other. This is what is meant by "concomitant"—that is, the straightening of the squinting eye is accompanied by the squinting of the other; and the fact that the patient squints first with one eye and then with the other also brings the case under the definition of "alternating." The deviation of the right or squinting eye is

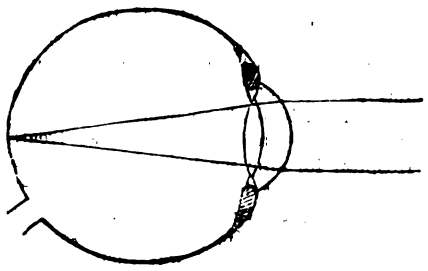
FIG. 5.



called the primary deviation; the deviation of the left or sound eye when covered, the secondary deviation. The primary and secondary deviations always correspond exactly in cases of concomitant squint; and it is essential to note this, because when the squint is due to paralysis the secondary deviation greatly exceeds the primary.

Here is a case of squint from paralysis of the external

Digitized by Google



rectus muscle of the left eye; the patient is a gentleman's servant, who is terribly embarrassed when called upon to pour out wine, because he cannot distinguish the true from the false image of the glass. Note, now, if I direct him to follow my finger with the squinting eye he moves it slightly, but cannot force it outwards, while the great effort he makes in this direction causes him to squint inwards much more with the right eye than he did before with the left. To appreciate the value of this symptom, you must remember

FIG. 6.

that you cannot turn the left eye outwards without at the same time turning the right eye inwards—they are associated actions; and when this patient makes an effort to turn his paralysed eye outwards, although he cannot effect his object, he is at the same time doing his utmost to turn the right eye inwards; hence the effect, although *nil*, or nearly so, on the paralysed external rectus of the left eye is greatly in excess on the healthy internal rectus of the right. This distinguishes cases of paralysis from cases of concomitant

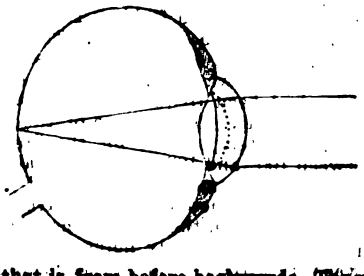


FIG. 7.

squint, and you will notice a similar association of symptoms in patients suffering from uncomplicated paralysis of the superior rectus, where, owing to the connexion of the central nerve ganglia of the superior rectus and levator palpebræ, the effort to look upwards raises the lid of the paralysed eye out of all proportion to its fellow.

Why should so many children begin to squint when they first begin to read, or write, or sew? Simply because they cannot see unless they do. Their eyes are too short in the

FIG. 8.

long axis—that is, from before backwards. The refraction is too low, and objects, instead of being focussed upon the retina, are depicted upon a spot a little beyond it; hence the patient makes extraordinary efforts to lengthen his eye, or increase its refraction, so as to bring the picture into its proper place. You will understand this at once if you compare the accompanying outline of the short eyeball (Fig. 6) with its fellow of the normal eye (Fig. 7). You may say, "What has this to do with squint? Squinting will not alter the shape of the eyeball." No, but it has a similar effect, as I will now explain. Patients whose eyeballs are too short are said to suffer from hypermetropia; they are obliged to exert a certain amount of accommodation—that is, render the lens optically stronger by increasing the curvature of its anterior surface by the active exercise of the ciliary muscle, even when looking at distant objects, an effort that is not at all required of the normal eye. Rays of light proceeding from objects twenty feet distant are parallel or nearly so, and, in an eyeball of ordinary dimensions, are brought to a focus on the retina by the power of refraction of the cornea and lens alone when the eye is at perfect rest, and without any exertion of the ciliary muscle. (See Fig. 7.) In hypermetropic persons it is necessary that the convexity of the lens should be increased before these parallel rays can be brought to a point as indicated by the dotted lines in Fig. 8, where the hypermetropic eyeball is seen successfully bringing parallel rays of light to a focus on the retina by increasing the curvature of the anterior surface of the lens, an effort which, in an eye of ordinary dimensions, is only required for the divergent rays which emanate from near objects. Now, if the hypermetrope is obliged to accommodate for distant objects, the rays from which are parallel, you can readily understand that considerable exertion is required in order to enable him to focus near objects, the rays from which are divergent; and this excessive effort of accommodation involves a squint, because the power of accommodation is greatly increased by convergence of the optic axes. Why, therefore, do we not cure squint by neutralising the hypermetropia with a suitable convex glass? A most rational suggestion; and no doubt great good may be effected in this way, as well as by paralysing accommodation with atropine. But, in point of fact, these patients do not come to us, as a rule, until they have squinted for some time; often they only do so because their lives have been rendered miserable by the scoffs and jeers of their schoolfellows and playmates. Prolonged treatment with spectacles constantly worn, and which only mitigate the defect, still subjects them to remark—indeed, tends to aggravate rather than diminish this serious evil, and consequently offers no attraction either to our patients or their friends. Moreover, it is dangerous for little children to wear spectacles out of doors or when at play; they are so apt to be injured by fracture of the glass, and, strange as it may appear, after they have squinted for some time they won't leave off, even though you give them glasses so strong that the squint, far from assisting, actually disturbs vision.

If a squint is neglected, as time goes on one eye becomes permanently the squinting one; it is definitely excluded from the act of vision, and from that moment sight begins to fail. First excentric portions of the retina lose their sensibility, then the yellow spot, and lastly the inner portion fails likewise. If you push one of your eyes ever so little on one side you immediately see double; there is a true image and a false image, and the deterioration of sight which takes place in squint-eyed persons is simply due to the constant negation of the pseudo image of the squinting eye by the brain. We only see what we look at; we only hear what we listen to; the brain has a horror of double images, and the persistent exercise of this mental act of suppression causes in time loss of function, amblyopia from exclusion, or exanopsia, as it is termed. As the patient ceases to see, so does the eye cease to be affected by efforts at convergence, but wanders to and fro in a purposeless sort of way, and is thus in occasional accord with its fellow; hence the friends, ignorant of the fact that growing out of a squint means growing blind in one eye, congratulate themselves, and become dubious as to the necessity for operation. When a squint alternates, sight may be restored and the deformity cured perfectly. When it has become monolateral the squint may be cured and the sight greatly improved if we see the patient within a reasonable time, but in advanced cases the chances of restoration to sight are greatly diminished; hence operation should not be unduly delayed, or if delayed from any unavoidable cause the eyes should be alternately exercised, so as to counteract loss of function from disuse. If the squint is very slight, it may be necessary only to operate on one eye; but in the great majority of cases, unless when one eye has become completely amblyopic, it will be necessary to divide the tendons of both internal recti. In the case of the boy patient on whom I am about to operate, we noticed that the eye, which was closed, whether right or left, became for the nonce the squinting one. Now, when both eyes are closed as in sleep, or, as you will be able to see, during anæsthesia, both squint, and the primary deviation, limited during

Digitized by Google

waking moments to one eye, becomes equally divided between the two, as in Fig. 9. Here is clear evidence of the binocular nature of squint, and you can readily understand that in the majority of cases it will be necessary to operate upon both eyes. The exigencies of practice and the convenience of the patients frequently necessitate a double operation at one *séance*. It is well, however, when it can be so arranged, to operate upon one eye only at a time. Cases where the eyes are equally convergent when in use are extremely rare, but I can show you a patient who habitually squints inwards with both eyes, exactly as represented in the sketch. (Fig. 9.) In fact she is very myopic, and has never worn glasses; hence the externi, which produce approximate parallelism of the optic axis required for distant vision, have never been exercised, while the interni have been equally and abnormally developed by constant convergence for near objects.

Some patients squint simply because they have a scar upon the cornea; in these cases a shadow is thrown upon the retina by the interposition of an opaque film, and the patient turns his eye so as to reduce the annoyance thereby occasioned by throwing it upon the least sensitive portion of the retina. In such cases it is often necessary to shift the pupil and tattoo the cornea as well as divide the rectus tendon. As before remarked, cases of squint, whether external or internal, which are due to paralysis of the third or fourth nerves, usually yield to medicine and treatment adapted to remove the cause, which may be of rheumatic, syphilitic, or diphtheritic origin, or may depend upon defective nutrition of nerve centres arising from various causes. These cases usually occur suddenly in adults or persons past middle life, increase rapidly, and are accompanied by distressing giddiness, which disappears when the affected eye is closed, and is mitigated, but does not wholly disappear

FIG. 9.

when the healthy eye is closed. Contrary to what you would *a priori* expect, a slight squint of recent origin is much more embarrassing to the patient than the graver varieties of the same affection. This is due to the fact that the nearer to the yellow spot on the retina, the more definite does the image of the squinting eye become, and the more difficult it is for the patient to distinguish the true from the false image, thus leading, as in the case of the gentleman's servant we have just seen, to serious error with regard to the position of objects.

The cause of paralytic squint may be central, such as disease of the spinal cord or brain; or it may be peripheral, arising from inflammation of the nerve sheath or pressure from tumour, gumma, or periosteal thickening, or even shock from cold. Facial paralysis, as you know, is often due to the latter cause, and the ocular nerves are occasionally affected in the same way. If the disease is of central origin the loss of power is usually only partial, more than one nerve is affected, and you will find that it is impossible to fuse the true and false images by means of prisms. Complete failure of any one of the nerves supplying the orbital muscles, unaccompanied by other symptoms of paralysis, may be confidently ascribed to some lesion of the trunk of the nerve itself at the base of the skull or in the orbit, and may thus be distinguished from the graver varieties of central origin. In treating these cases, you will find large doses of iodide of potassium, with mild mercurials, most serviceable in one class of patients; change of air, tonics, and general hygiene in the other. Strychnine, internally and hypodermically, with the local application of the induced or voltaic electric currents, are applicable to both; and whenever the paralysed muscle responds to the stimulus, however slightly, you may confidently predict a successful issue to the case.

Practice and attention to the rules I have laid down will enable you to command brilliant results in cases of squint. We have operated upon thousands of patients at this institution. It is a rule that each shall return within a few months, so that we may note the ultimate result. One easily forgets faces in a large practice, and it frequently happens, as you know, that I fail to recognise my friends, so completely has the deformity been removed. I must warn you, however, that this desirable end cannot always be attained by one operation; indeed, the most strikingly successful immediate results in cases of convergence (the most common form of squint) are those most likely to be followed by divergence. We must, therefore, be careful not to do too much at once, and it is well to warn the patient or his friends that more than one operation may be necessary. At the next lecture I hope to show you some interesting cases of optic and ciliary neurotomy.

CASES OF ŒDEMA OF OBSCURE ORIGIN.[1]

BY W. B. HADDEN, M.D. LOND., M.R.C.P.,

DEMONSTRATOR OF MORBID ANATOMY AND MEDICAL REGISTRAR TO ST. THOMAS'S HOSPITAL, PHYSICIAN TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.

S. S——, aged twenty-four, a dressmaker, was admitted under my care into the Royal Hospital for Children and Women on Nov. 3rd, 1884. There was a very marked history of phthisis in the family. The patient stated that she had suffered from vomiting and headache occasionally since childhood, but during the last four years she had become much worse. In October, 1882, she was an in-patient of St. Mary's Hospital, under the care of Dr. Broadbent. She was stated to have suffered from gastric ulcer and peritonitis. At this time she began to have constant diarrhœa, and this has persisted ever since. Soon after leaving the hospital in January, 1883, she became very weak, and had swelling of the legs and feet. She was treated at the Reading Hospital for nine weeks, and remained quite well for two months after her departure. In June, 1883, she was again attacked with vomiting and pain, and in October she was admitted into Guy's Hospital, where she was seen by Dr. Wilks and Dr. Pavy. She was then thought to have acute peritonitis. In January, 1884, she was admitted into the Beckenham Hospital for another attack of supposed peritonitis, and since then she has had several short bouts of similar nature. A month before she came under my notice she caught cold, and has had a cough since. On admission she complained of pain in the epigastrium and right iliac region, and of extreme weakness. She was very thin, apparently emaciated. The skin everywhere was hot, dry, and very scurfy. Both legs were œdematous, the left more than the right. There were the signs of bronchitis all over the chest, but no evidence of consolidation. She had little cough, and did not expectorate. The heart was normal. The pulse was 92 and feeble. The urine was free from albumen, and normal in every way. The liver seemed natural. On Nov. 8th (five days after admission) she was much better. The pain was less, and there had been no vomiting. There had been frequent stools, sometimes as many as eight or ten daily. The œdema of the lower limbs had disappeared. The temperature for the first four days had varied between 100° and 103·8°, being usually higher in the evening than in the morning. She had sweated at night, and on one occasion there was said to have been a slight rigor. The physical signs in the chest remained as on admission. I need not give the daily notes of the case. The temperature was very variable, sometimes reaching only 100° at night, sometimes rising to 102° or 103°, and occasionally remaining normal. The night sweats continued, and at times she had slight shivering attacks. The tongue was very red. The stools were still frequent, but not so frequent as at first; they were pale, formed, and small. The tendency to frequent defecation was controlled by compound kino powder, ten grains twice a day. She had only

[1] Read before the West Kent Medico-Chirurgical Society, 1886.

Digitized by Google

vomited twice during her stay in the hospital, once after a dose of cod-liver oil. The catamenia, which had been absent for more than a year, appeared once. In short, when she was discharged at the beginning of 1885 she was practically well.

And now I must give the patient's subsequent history. In May, 1885, she came under Dr. S. Coupland's care at the Middlesex Hospital. She again had the signs of bronchitis, the legs were œdematous, she vomited at intervals, usually after food, and the stools were frequent. The pulse was noted as being feeble and compressible. The urine was examined several times, and always found free from albumen. The temperature, again, showed an irregular tendency. She made considerable improvement; but I gather from the clinical notes which were kindly lent to me by Dr. Pasteur, the medical registrar, that there was still slight œdema of the legs and some bronchitis when she left the hospital. In October, 1885, I received a letter from my friend Mr. Lunn, the resident medical officer at the St. Marylebone Infirmary. He asked me to come to see a case which might possibly be one of myxœdema. I found that the woman was my old patient. Her aspect had undergone a very remarkable change. Both upper and lower eyelids were very much swollen, so swollen that she was unable to see me; otherwise there was no puffiness of the face. I must observe that Dr. Coupland's notes state that the patient had noticed swelling around the eyes in the morning for nine months. But there was certainly no puffiness when she was under my care, and I found no reference to its existence in the Middlesex notes. In addition to the swelling of the eyelids, the legs were œdematous, and there were the signs of bronchitis. I could detect nothing wrong with the thyroid gland. There was no evidence of obstruction of the veins of the lower limbs. On the whole, I thought that the case was not one of myxœdema, but, on the other hand, was not prepared to give anything like a positive opinion. She remained at the St. Marylebone Infirmary from June 17th until her death on Oct. 27th, 1885. During this time she suffered a good deal from abdominal pain, vomiting, and diarrhœa. The urine was repeatedly examined, but never contained albumen. The average daily quantity was said to have been only fourteen ounces, but probably a considerable quantity was passed in addition during her frequent defecations. On Oct. 20th the œdema had entirely disappeared, but the abdominal pain persisted, and the stools were passed at frequent intervals. She died rather suddenly on Oct. 27th.

I was unable to be present at the post-mortem examination, but Dr. Coupland attended. The heart, liver, spleen, kidneys, uterus, and brain were normal. The thyroid gland was said to be small, but apparently not otherwise affected. The lungs were large, emphysematous, and œdematous, but there was no sign of consolidation. The omentum was large and fatty. The mesenteric glands were enlarged, and several were suppurating. Three annular strictures were found in the jejunum at intervals of four inches, and one of these was plugged by a plum-stone. Unfortunately, I cannot report on the condition of the blood and vessels, the exact state of the thyroid body, and the precise nature of the intestinal strictures. I am, however, informed by Dr. Coupland that the real nature of the disease was not made clear to his mind by the post-mortem examination. I cannot connect in any reasonable way the œdema of the lower limbs and face with the state of things found after death. It is true that the œdema of the legs might be due to the bronchitis, although my own belief, after a careful study of the case, is that such an explanation is insufficient. The puzzling factor is in the later history of the patient. The swelling of the eyelids suggested renal disease; but, as I have already observed, neither clinical nor pathological evidence lend the slightest warrant to this hypothesis. It would be impossible, too, from the facts which I have given, to look upon the condition as one of myxœdema or the cretinoid state; indeed, I am prepared with no explanation. The enlargement and apparent inflammation of the mesenteric glands, and the strictures of the small intestine are, of course, a sufficient and reasonable cause for the abdominal pain and the frequent defecation. But it is difficult to connect the œdema with these lesions, and it is highly probable that there was no other relation between them than that of mere coexistence. The occurrence of transitory œdema is not unfrequent in the initial stages of myxœdema. The swelling may affect face, limbs, or trunk, and may supervene more than once before the characteristic features of the disease are exhibited. It is well, therefore, to bear in mind the possible significance of some of these fugitive œdemas of obscure origin.

In talking over this subject recently with Dr. Bristowe, he reminded me of the case of one of the present house-physicians at St. Thomas's Hospital. This gentleman, who gives me permission to allude to his case, informs me that about two years ago he suffered from œdema of the upper and lower eyelids on the right side. At this time he was in his usual condition of health, which, however, is never very robust in London. The urine was constantly examined for albumen, but none was ever found. He was seen by Mr. Nettleship, who suggested some periostitis as a possible cause. But this was abandoned as untenable, as there was an entire absence of pain, heat, or thickening of the surface of the bone. There was no sign of enlargement of the superficial veins. In fact, the case was one of passive œdema, and its cause still remains unascertained. In two weeks the swelling disappeared, much to the satisfaction of my friend, who was not unnaturally somewhat alarmed. He tells me that his eyelids have always been slightly full, and at the present time they are certainly a little puffy. During the last two years I remember a few cases of œdema of unusual distribution, the cause of which was not clear. One was a child, fifteen months old, the subject of slight rickets, who had œdema of the right foot and the left hand. Another was an infant of the same age, who had œdema of both legs; but the friends stated that during the four weeks preceding admission there had been occasional swelling of arms and hands. In both these instances the origin of the dropsy remained undiscovered.

The case which I shall now give proved fatal, but the post-mortem examination only partially explained the clinical facts. The patient was a woman aged twenty-eight, who came under my care at the Royal Hospital for Children and Women on Jan. 12th, 1886. The only point to note in the family history was that her mother died of phthisis. The patient had been married four years, but had never been pregnant. She had always been delicate, though she had suffered from no definite illness since measles in childhood. The catamenia had been absent for the three months preceding admission. She had been troubled with cough in the winter, and of late the cough had become more severe. During the last six months there had been pain and swelling of the legs, and she had become weak and thin. On admission she was seen to be fairly nourished, and the lips were of a good red colour. The cheeks were swollen and puffy, but the eyelids were not affected. The hands were cold and the skin on the dorsum mottled. The abdominal and thoracic walls were œdematous, and there was marked dropsy of the legs and feet. There were sonorous and sibilant rhonchi over both lungs. The left apex, both front and back, was dull, and crepitations were audible. The respiration was cavernous, the voice sounds increased, and pectoriloquy was present. In fact, the existence of a cavity was diagnosed, and the post-mortem examination showed that this was so. The heart was normal. The pulse was 128, regular, and very feeble. The liver was evidently enlarged, the edge being felt three inches below the ribs. No ascites was made out. The tongue was furred, the appetite bad, the bowels regular. The specific gravity of the urine was 1025; it was acid, and contained no albumen. No alteration in the size of the thyroid gland could be detected. The temperature varied between 99·6° and 101°. On Jan. 19th (one week after admission) I noted that the whole left upper extremity was œdematous, pitting on pressure. This had been noticed the day previously by the house-surgeon. The right forearm and the lower part of the arm were also œdematous, but were not so when the resident surgeon had made his morning visit two or three hours previously. There was no enlargement or tenderness of veins anywhere, and no sign of mediastinal growth or aneurysm. The feet and legs were now only slightly œdematous. During the night she had had diarrhœa, the stools being loose and offensive. During this first week the patient had been treated with stimulants, such as brandy and ammonia.

Jan. 21st: The œdema of the right arm has disappeared, but around the left elbow it is more marked. She has been slightly delirious during the night. No headache. Feet and legs remain as before, slightly œdematous.—23rd: The œdema of the right upper extremity has returned, the lower half of the arm and the upper half of the forearm being affected.

Digitized by Google

The œdema in the left side has increased somewhat, and extended a little further down the forearm than on the opposite side. The backs of both hands are absolutely free from œdema. There is no fulness of veins, no tenderness, and no swelling of face; some œdema of lower half of back. The diarrhœa has been controlled by occasional doses of chalk mixture. The pulse is 112, and still very feeble. The urine, after repeated examinations, was found to be free from albumen.—25th: The œdema of the left upper extremity has extended to the dorsum of the hand. The right arm is now but slightly affected. There is some swelling and pitting of the right side of the neck.—26th: The œdema of the neck has nearly disappeared. She passes her evacuations into the bed. Is taking a tablespoonful of cod-liver oil twice daily, in addition to the ammonia mixture.—30th, 11.30 A.M.: No œdema of arms or legs, but some of back and abdominal walls. 1 P.M. (an hour and a half later): There is now moderate œdema of upper half of forearms.—Feb. 2nd: Slept fairly in the night, but was delirious in the morning. Suddenly became collapsed while having her bed made. She does not seem to understand when spoken to. She is very pale, and the eyes are half closed. Pulse 140, very feeble. Had a general convulsive fit shortly after midday. No œdema anywhere.—3rd: The coma has increased, and she cannot be roused. Had several convulsions during the night. She died at 9.45 P.M., after a series of epileptiform attacks.

Necropsy, seventeen hours after death.—No œdema of extremities. Hair in axillæ and on pubes very scanty. Thyroid gland healthy. Two pints of serous fluid in left pleura, and firm adhesions at apex. Right pleura healthy. Three or four ounces of serous fluid in pericardium, and two pints in abdomen. The upper lobe of the left lung showed rather extensive broncho-pneumonic and tubercular consolidation. There was only one cavity, and that was situated at the extreme apex close to the posterior border. It was well defined, measured an inch from above downwards (its long diameter), and contained pus. The lower lobe was quite collapsed, and there were a few caseous masses, averaging the size of a pea, scattered through it. There were some broncho-pneumonic patches at the extreme apex of the right lung, but no cavity. The bronchi contained pus. The bronchial glands on the left side were very caseous. The right side of the heart was dilated, but the organ was otherwise natural. The blood was everywhere fluid, except for a small amount of clot in the right side of the heart. The vessels, both arteries and veins, were healthy. The main veins of both upper and lower extemities contained fluid blood only. There was no obstruction. The liver was large and fatty. The spleen a little enlarged. The kidneys were somewhat increased in size, and heavier and firmer than natural. The capsule stripped readily, and the convex surface was smooth; the cortex was dull red, but otherwise natural. There was some early tubercular ulceration on the lower part of the ileum, and there were two or three calcareous mesenteric glands. The os uteri was small, and each Fallopian tube showed a constriction about its middle, the inner half being much narrower than the outer half. There was a moderate amount of fluid in the ventricles of the brain, otherwise the organ was healthy.

There are some points in the clinical history of this case which require special notice. The patient throughout was extremely feeble, and her weakness seemed to me to be quite out of proportion to the amount of lung mischief. The urine was frequently examined for albumen, and on only one occasion was it present, and then there was only a trace. The temperature exhibited as a rule an evening exacerbation, and, in fact, had the features so often seen in phthisis. I made careful inquiries as to whether the position of the patient had any influence over the curious distribution of the œdema, but the nurses were confident that such was not the case. The fluidity of the blood found after death may possibly explain some of the peculiarities of the dropsy in this patient; but I confess I cannot readily account for its occasional fugitive character; nor, indeed, is it easy to understand why the œdema should affect part of the arm and forearm—for example, leaving the back of the hand free. I am not aware that much has been written on the subject, which I have brought forward in rather a disconnected way. I have preferred to record facts, and to say little by way of explanation, for I trust that others may, from their ripe experience, be able to throw some light on this obscure class of cases.

ON THE NATURE OF SCROFULOUS GLANDS IN THE NECK AND THEIR SURGICAL TREATMENT.

BY KENDAL FRANKS, F.R.C.S.I.,
SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

(*Concluded from page 1156.*)

MY excuse for having gone at some length, and yet as briefly as I could, into the pathological aspect of the subject, must be that upon our view of the question in this light the further question of surgical treatment is based; and also that in most of the works in our own language the tubercular nature of the disease is not recognised sufficiently. In support of this assertion I will quote a few passages from some of the more recent surgical works which deal specially with the subject of scrofula and tubercle. In the first volume of Ashhurst's "International Encyclopædia of Surgery," p. 242, in the article on Scrofula and Tubercle, written by Mr. Butlin, and published in 1882, he thus speaks of the morbid anatomy of scrofula: "There is not in scrofula, as in tubercle, a pathological body, either microscopical or of larger size, peculiar to the disease. All the changes are those of inflammation; but the products of scrofulous inflammations may be analysed, chemically and histologically, without the discovery of any substance or structure which may not equally occur in any, or indeed in every, inflammation." This was no doubt written immediately before Koch's address before the Physiological Society of Berlin, but it does not even represent the position of the question as it stood for several years prior to the discovery of the bacillus. The identity of the two diseases had been fully recognised by leading pathologists, as I have endeavoured to show; the only question waiting for solution being "What is tubercle?" Again, in Mr. Treves' work on "Scrofula and its Gland Diseases," published also in 1882, p. 20, after giving the evidence for and against the identity of these diseases, he proceeds to discuss the value of the inoculation experiments, especially with respect to the conclusions drawn from them by M. Villemin. He then makes almost a pathetic appeal in favour of scrofula and its future distinctive existence. He says: "But even now some pathologists still advance the opinion (which I give in the words of M. Villemin) that 'tubercle alone gives tubercle by inoculation.' Those who retain this view are compelled to exclude from scrofula all its classical features: the caseous gland, the cold abscess, osteitis, periostitis, and 'white swellings'; and all that they can leave for the disease are a few superficial lesions, the products of which will in time be probably found to be inoculable, and then, for M. Villemin and his followers, scrofula will be an extinct disease." Well, terrible as the alternative is, we must face it; and as we must now hold that "tubercle alone gives tubercle," and that, as the bacilli from scrofulous lymphatic glands, when inoculated, give rise to tubercle, we must also hold that scrofulous lymphatic glands are tubercular; Mr. Treves will have to accept his alternative and acknowledge that scrofula as a distinct disease has ceased to exist. Let me cite another extract, one from Dr. Clifford Allbutt's lecture on "Scrofulous Neck," as it illustrates the dawn of the tubercular aspect of the disease in these countries. He says in his lecture published last year, p. 12: "Our knowledge of the tubercle bacillus is as yet too young to tell us whether scrofulous neck always depends upon the introduction of the tubercle bacillus by way of the mucous membrane of the throat or otherwise—too young, indeed, even to tell us whether the tubercle bacillus is an essential part of scrofulous neck at all. We know that it may be found there, and that scrofulous neck has of late years been regarded as morphologically tubercle, so that we are safe at least on the broad postulate that inoculation from sources of corrupt or caseating pus does very commonly set up a more or less generalised tuberculosis." I do not wish to assert that every enlargement of the cervical lymphatic glands is tubercular. We eliminate in this discussion those forms of adenitis which are associated with various infectious and simple inflammatory processes; we omit the so-called rheumatic bubo which appears in otherwise perfectly healthy individuals, without discoverable cause, most frequently in the axillary and inguinal glands, and which often terminates in suppuration.

Digitized by Google

In fact, only those affections of the gland are here discussed to which the term scrofulous is usually applied, and these, we assert, are due to the specific action in them of the tubercle bacillus. The diagnosis in the early stage is extremely difficult, indeed sometimes impossible, between the tubercularly infected gland and the simple form of adenitis which results from some local irritation. Thus the glands in the neck may enlarge from the irritation caused by a carious tooth, or an attack of tonsillitis, or a simple cold. But as the irritating cause disappears the swollen gland will subside, though sometimes it takes a long time to do so. But in the tubercular gland it is quite otherwise. The irritating cause may disappear or have been so slight as to escape notice, but the infected gland remains stationary for a time or continues to enlarge, and presently we find other glands following in its wake, and enlarging too. In the early stage our only means of diagnosis is to wait, and what was at first obscure will soon be cleared up by the future progress of the case.

Now, to understand the process of infection in the cases referred to, we must for a moment look at some of the characteristics of the bacillus itself. It cannot develop in a temperature below 86° or above 106°; therefore, outside an animal body it cannot grow in this climate. Inside the body it grows and multiplies. A bacillus takes a month to reach its fullest development. It multiplies by fission, and by the formation of spores. These speres are much more resistant than the bacillus itself. Drying the bacilli or the spores does not destroy them. It is not therefore difficult to understand how easily the infection may spread. The sputa of phthisical patients, for example, swarm with them. When these sputa dry, the bacilli and their spores, in a dry but active state, are scattered far and wide in the air, and may come in contact with a suitable soil whereon to develop. An ordinary healthy individual does not present this soil. The bacilli may be inhaled into his lungs, may be swallowed with his food or mixed up in his saliva, they may even lodge on some abraded mucous surface, and yet may do no harm. The antiseptic power of healthy living tissue is fully recognised. But there is undoubtedly some defect of constitution, some "vulnerability" of the tissues which we do not understand, which furnishes a fruitful soil. Call scrofula, if you will, the peculiarity of the soil on which the bacillus grows; but the seed itself and its growth, and the manifestations of its development, let us call tubercle. We shall thus have clear ideas, at least, as to what we mean; we shall not continue to confound together the soil, and the seed which grows on it. Now, look at the behaviour of the bacillus when once it finds a local habitation congenial to it. As I have said, a bacillus requires nearly a month for its full development, and shows hardly any signs of growth under a week or ten days. During this period they may be cast off in the bronchi by the action of the cilia; in other regions they may be expelled with the secretion of the part. But suppose they gain an entrance though some abraded part—they are taken up by the lymphatic vessels and carried to a neighbouring gland, or they may develop in the tissue where first they found a resting-place. In the case of the glands in the neck, we can generally trace the history back to some such local infection. Thus a child suffers from eczema of the head, and the child is of a delicate constitution; we are told it is scrofulous. Or the child has a purulent otorrhœa or ulcers in the mouth, or it suffers from a discharge from the nose. Later on, a gland in the neck, usually only on one side, enlarges. Or a young adult, and sometimes even one more advanced in life, suffers from a cold, from an attack of tonsillitis, or from enlarged, sometimes caseating, follicles in the pharynx (and I have not infrequently traced it to this cause); and even after this ailment has subsided, and is perhaps forgotten, a gland, or more, begins to swell. Long after the exciting cause has ceased to act, the gland either remains *in statu quo*, hard, nodulated, movable; or it may develop rapidly all the series of phenomena which are known as scrofulous. Other glands enlarge, and frequently we find all the glands on one or on both sides of the neck sharing in the process. This whole series of events are explained by what we know of the behaviour of the tubercle bacillus. By some such channel as I have mentioned the bacillus enters; it is taken up in the lymph streams, and is arrested by the first lymphatic gland it meets. In such cases too much importance cannot be attributed to the functions of the lymphatic glands. They act as defensive outposts, as filters to free the lymph of infective and deleterious matters which it may contain, but in doing so they themselves suffer. In process of time the bacillus grows within them, multiplies, and gives rise to the formation of true tubercle. These tubercles become yellow in the centre, they coalesce, and in process of time form a caseous mass. At this period one of three things may happen—in other words, the gland may follow one of the proverbial "three courses." First, it may get well, though this is not a frequent result. Secondly, it may suppurate,[1] make its way to the surface, and discharge its contents, and this may end in cure. Or, thirdly, it may extend, infecting gland after gland. Even here, too, nature may accomplish a cure by a slow process of successive suppuration, which may eventually eliminate the disease. But should nature fail to do so, the last gland between the bacilli and the general circulation may become infected, the last outwork of defence may be carried, and then the whole system is exposed to general infection, and a more or less acute general tuberculosis results. But what is to determine which of these three courses shall be followed? It seems to depend on one or other of two factors: firstly, on the number of the bacilli which have gained access to the gland; secondly, on the constitution of the patient. Koch has shown that it is of the greatest significance whether the infection be produced by a few bacilli or by a large number. In his inoculation experiments, he found that a large number of bacilli, after first producing a diffuse caseous infiltration, both at the site of injection and in the neighbouring glands, gave rise rapidly to general tuberculosis. If the number of bacilli introduced were smaller, the length of time which preceded general infection became longer; and when the bacilli were few, this period might be very long, or in some cases generalisation might not occur at all. In spontaneous tubercular infection in man the dose is usually small, though sometimes it is often repeated; and hence it is that in tuberculosis of the glands in the neck general infection of the system most frequently does not occur. The constitutional condition of the patient plays a part only second to the strength of the dose received. I have already alluded to the fact, recognised by all, that a certain state of the system, a certain constitutional susceptibility, is necessary, in order that an individual may contract tubercular disease—that is, that every person does not offer a suitable soil for the growth of the bacillus. What is equally true is that persons may possess this vulnerability in different degrees, and, moreover, that the same person does not afford at all times the same suitability of soil. Clinical experience has taught us this over and over again, and upon these axioms are based all our constitutional methods of treatment, the importance of which in every case cannot be over-estimated. In every case, whether we adopt surgical measures or not, we should aim at so improving the health of the patient by those means, which it is not within the scope of this paper to discuss, that to the best of our ability we shall put him into a condition to contest successfully with his unseen foes.

Taking, now, these two factors, we see that even when a gland has become infected we may hope for spontaneous resolution, provided that the infecting dose has been small, and provided that the patient's constitution has so improved that the gland tissue is healthy enough to cope with the bacillus. Now what do we observed in such a case? The bacilli gradually disappear from the caseous mass, and may not be finally found at all, and the broken-down tissue may be absorbed, or it may calcify, and recovery ensue. This is unfortunately a rare occurrence. But supposing these factors are not sufficiently strong to bring about such a desirable end, the patient may eliminate the disease by a process of suppuration. The caseous masses in the gland—and they are usually multiple—begin to show evidence in the centre of suppuration. This may go on to a considerable extent before any external symptoms of suppuration appear. So that because a gland is hard and movable, and is not tender to touch, we cannot assume that that gland does not contain many central abscesses of small size. Gradually these abscesses coalesce; the gland becomes tender; it enlarges more and more; inflammation extends to its capsule and to the neighbouring parts, and soon adhesions form. By slow degrees the skin over it becomes involved; it becomes firmly adherent; it thins; the abscess opens and discharges, and a sinus is left, which may, and generally does, keep open for weeks or months, discharging a thin pus

[1] This suppuration is not a necessary result of caseation, but is probably due to the entrance of some form of micrococcus by the same or some other channel as that by which the bacillus entered.

Digitized by Google

with cheesy matter contained in it; and when it heals it leaves behind it an ugly and disfiguring and puckered scar. But, even so, the patient is well quit of his disease. More frequently, however, the bacillus has made its way into neighbouring glands. One by one these enlarge, and the same slow process of suppuration begins; another sinus forms through unhealthy purplish skin, and another scar is left; and the cycle is repeated till the whole neck is seamed and unsightly. Is not this a true picture of the disease, and one with which we are too commonly familiar? If more were needed to paint it in its true colours, let me give it in the eloquent words of Dr. Clifford Allbutt: "That the ugly finger of scrofula should be laid chiefly upon children, young men, and maidens, has this pathos in it, that it disfigures them at the spring-time of life—at that time when hope and promise make all life precious, and all death seem the loss of untold treasure; when beauty and gaiety have their fleeting day, and for the loss of them the world is poorer."

But even while this local process of decay is going on the general system is not safe from its ravages. As long as these caseous masses of tubercle exist in the body, so long must we ever bear in mind that the danger of generalisation is possible. But even if we were sure that by repeated and prolonged suppurations the danger of extension were removed and the bacilli expelled, the scarring of the neck is not the least consequence which may follow. Remember that this disease would never have originated but for a peculiar constitutional susceptibility. Will that susceptibility be diminished by months or years of suffering? Will it not rather be enormously increased? During this period "septic matters are absorbed into the blood, recurrent and variable hectics dissipate the appetite, flesh, and strength, so that the patient finds himself at the end of it all, if not unsound in his internal organs, at any rate a far worse man than he would have been had this trial been spared him."[2] Let him become again exposed to tubercular infection, let him breathe impure air impregnated with tubercular poison, and who shall say that he will escape with healthy lungs? It is believed by some that in subjects predisposed to scrofula the involvement of the glands in youth affords them some sort of protection against phthisis subsequently. But this view cannot be upheld. Only the other day a girl came into hospital with extensive disease of both lungs, and her neck was seamed with old scrofulous scars. The worst case of tuberculous glands in the neck I ever saw was in a girl who died of phthisis.

Such then, being the nature of these so-called scrofulous glands, and such the consequences which we have to face, I think I am justified in asserting that the time has come, when the treatment of this disease, except in its earliest stage perhaps, should pass from the domain of the physician, and should be entrusted to the surgeon. In the earlier stage, while still the diagnosis remains uncertain, the treatment is one of expectancy, tempered by constitutional measures. But when once the diagnosis is assured, and there is no evidence that resolution is likely to take place, bearing in mind the nature of the disease we have to deal with, and the consequences which may follow from waiting too long, I am strongly convinced that the surgeon's art should intervene to assist Nature, and to do that quickly, which unassisted she would do if she could, but often fails in accomplishing, or only succeeds when her victory has cost her dear. When as yet the poison has infected but one or two glands, we have good grounds to hope that by their removal we may eliminate from the system every focus of infection. Every case is not suitable for the same method of treatment, and in some cases we have little choice left to us as to what method we shall adopt. Of all the various surgical methods at different times suggested, there are three which I shall specially refer to as being the best. Each one is applicable to a different class of cases, and although they have been applied indiscriminately by their special advocates, I think there are well-marked lines which should divide those cases in which a special method is applicable from those in which it is not. These three methods are (1) scooping, (2) cautery puncture, and (3) excision.

Of the first method—scooping—I need say but little, as the subject has been very fully and ably discussed in a lecture by Mr. Teale, which was [illegible] last year.[3] I [illegible] with which I [illegible] healing in [illegible]

a few weeks of gland cavities and sinuses, even though they have existed for years, and of wounds resulting from the removal of caseous and suppurating glands." 2. "That in dealing with sinuses, gland abscesses, and decayed or semi-decayed lymphatic glands, the action of the surgeon must be vigorous and thorough." 7. "That in dealing with a sinus the channel should be enlarged by the knife or by Bigelow's dilator, and the whole of its granulating surface should be scraped off. Where a sinus is shallow and covered by thin blue skin, this imperfect covering should be rasped away by the scraper, and any cutaneous overhanging edges should be trimmed off by the scissors." 8. "That, in dealing with a sinus or an abscess, the surgeon should not rest content until he has discovered and eradicated the gland, always remembering that if it be not obvious there is sure to be a small track leading through the deep fascia to the missing gland. This opening should be enlarged so as to admit the spoon of Lister's scraper." These conclusions which I have quoted explain the classes of cases to which, I think, this method is suitable, and to which I believe it should be restricted. These classes embrace cases in which sinuses exist, or in which a superficial abscess communicates through an opening in the cervical fascia with a suppurating and caseous gland beneath. It is also sometimes a good treatment to adopt when the changes going on inside a gland have given rise to inflammation of its capsule and to the formation of firm adhesions between it and its surrounding tissues. For in these cases enucleation of the entire gland is extremely difficult. I have employed this method in many cases, and my experience of it has strongly impressed me with the belief that the classes of cases I have mentioned are those to which the method should be restricted. For in all of these cases the method of excision is fraught with too much difficulty to authorise us to adopt it in preference to this apparently simpler plan; but, on the other hand, it should not be extended to cases in which enucleation can be readily performed, and for this reason. In most of these tuberculous glands, the gland capsule shares in the disease, and in the scooping operation this is necessarily left behind; moreover, there may be, and there frequently are, enlarged and tuberculous glands in the neighbourhood, which have not yet softened. These escape the spoon, and later on become the foci from which fresh infection starts. Of much less importance is the fact that the incision after enucleation seldom takes more days to heal than that after scooping takes weeks. On these several grounds, I hold that the scooping operation should *only* be done in those cases in which excision is inapplicable.

The second method of treatment is that by cautery puncture. It has found its chief advocate in these countries in Mr. Treves,[4] and it has also found much favour in France. Mr. Treves expresses the opinion that it is "one of the very best operative measures at the disposal of the surgeon for the cure of scrofulous glands." He thus describes it:—"In this operation I make use of a thermo-cautery point about as thick round as a No. 7 catheter. This point, having been heated to a bright-red heat, is thrust through the skin into the substance of the gland, and passed in three or four directions in the body of the tumour before it is removed. ..... If no pus or cheesy matter follows the removal of the iron a simple zinc dressing may be applied, but if any such matters escape then a poultice should be ordered. ..... It is more adapted for adherent than for movable glands." This method I have lately employed, and in certain cases I think it should be productive of good. Its *modus operandi* would seem to be that the intense heat destroys the tubercle bacilli and their products, and it leaves a channel for their escape externally which does not allow of extravasation into the neighbouring cellular tissue. It seems to me that in softened adherent glands, it would probably be more effective than the method of scooping.

The third method of dealing in a radical manner with these tuberculous glands is by excision. It is specially suitable in those cases where the glands are not adherent. The operation is easier the harder the glands are—that is, the less advanced they are in the process of suppuration. The great advantages I claim for this method are that we can in most cases entirely remove all the affected parts, including the capsule of the gland. The wound is a clean [illegible], mostly through healthy skin, and therefore, with [illegible] sepsis, heals by first intention, and leaves a [illegible] becomes of time becomes white and often [illegible]

[illegible] Scrofula and its Glands [illegible]

Digitized by Google

glands are non-adherent, they can be enucleated with great ease. On the 8th of this month, through an incision an inch and three-quarters long, I removed eight glands, three as large as walnuts, and all of them caseous. Seven days after, the wound was healed, and the scar even then scarcely noticeable. But when the tubercular process has been allowed to run its course for a long time, and adhesions have formed, then the real difficulty is experienced, and often a tedious dissection is required before the diseased glands can be removed. And here let me say that this difficulty is often of our own making. We meet a case in which two or three glands in the neck are swollen and hard. A careful inquiry into the history of the case will satisfy us that the glands are scrofulous. But instead of dealing with them at once, we allow the disease to spread, more glands to become infected, and adhesions to form, whilst we wait. Wait for what? To try the effects of this or that external application, painting with iodine, or a host of other remedies, which experience should have taught us in that stage are no remedies at all. Sometimes the delay is due to our unwillingness to make a cut which may leave a scar, and then nature takes the matter in hand, the gland softens, an abscess forms, and the end of it is that a far worse scar is left than would have resulted from timely intervention. Besides, all this time other glands are preparing to go through the same process. Such things ought not to be. What I maintain is, that the earlier we attack these glands the less we shall have to do, and the smaller and more insignificant the scar will be; and, what is more important still, the focus of the disease may be got rid of through quite a small opening. Often, however, we have at least this satisfaction, that we cannot blame ourselves if the disease has become extensive. It may be so when first we see the patient, but even in the most extensive cases of scrofulous glands we may hope for a cure by surgical art. I have notes of fifteen patients from whom I excised tuberculous glands. Two were operated on twice and two three times, making in all twenty-one operations. Some of these were comparatively simple cases, two or three glands only requiring removal. Some of the cases were most extensive, and of these three present points of special interest.

The first case was that of a boy aged seventeen, whose neck was enormously swollen on the right side, owing to the enlargement of the glandulæ concatinatæ and submaxillary glands. I operated on him twice. The first time was on June 12th, 1883. A curved incision, about four inches long, was made behind the sterno-mastoid muscle, and all the enlarged glands removed. They were all caseous, several presenting centres of suppuration in the middle of the cheesy masses. I mention his case because he was attacked with erysipelas three days after operation. The erysipelas began low down on his back, spread gradually over his whole body, with the exception of the parts underneath the antiseptic dressings. This part remained healthy throughout, and the wound healed well. Some months after I removed the submaxillary glands. A similar mishap occurred in a second case, but both made perfect recoveries.

The second case I wish to mention was that of a married woman, aged twenty-three, who presented a long chain of glands extending from behind the left ear to the clavicle. They were movable and hard in the upper two-thirds, but below they were soft and suppurating. I excised them all at one operation on April 3rd, 1884. The abscess cavity was scraped out, and a drainage-tube inserted through a counter opening close to the clavicle, the wound being itself completely closed. The dressings were not disturbed till the seventh day, when the wound was quite healed. The drainage-tube was removed, and the sinus was completely healed on the fifteenth day. She left hospital three days later. I saw her again a few months ago, a year and three quarters after operation. There were no more enlarged glands, and the incision was reduced to a fine white pliant scar.

The last case to which I shall refer is that of a girl aged eighteen, who was studying to become a schoolmistress, but was rejected on the ground of health, as the left side of her neck was bulged out with a large number of swollen glands. She was greatly disfigured. I operated on the 29th of April, 1884. The incision reached from the mastoid process to within an inch of the clavicle. All the superficial and deep glands were involved, those lying underneath the sterno-mastoid muscle being very difficult to enucleate. I removed in all forty-eight glands at this operation. She made a slow recovery, but a good one. I saw her the other day, nearly two years after operation. There is a long scar, but it is soft, white, and flexible; and she can so arrange her hair as to make it almost imperceptible. She is in excellent health, and has had no return of the disease; in fact, as we might expect, it is not possible to feel any glands in that side of the neck. I mention this case especially as showing that excision can be safely done, even in such an extreme case.

Before concluding this paper, there is an objection which I should like to answer—an objection which I have heard raised, especially in regard to these extensive operations; and it is this: Is it not a very serious matter to interfere to any great extent with the lymphatic system in the neck? That objection is entirely theoretical; I have not seen in any of the cases on which I have operated any evil consequence referable to this cause. Besides, we must bear in mind that caseous glands are, to all intents and purposes, functionally destroyed. If there is any reason in the objection at all, the blame must be left at the door, in the first instance, of the tuburcular affection; and, secondly, at the door of those, be they doctors or patients, who allow the disease to progress to such an extent—a disease which, I trust, I have shown can be arrested in its early stages by the timely and judicious intervention of surgical art.

NOTES ON A CASE OF EXTRA-UTERINE ABDOMINAL PREGNANCY.

BY T. W. J. ALLEN, L.R.C.P. LOND., &c.,
HONORARY SURGEON TO THE GRIMSBY AND DISTRICT HOSPITAL.

MRS. ——, aged thirty, fisherman's wife, consulted me on June 27th, 1885. She was of slight build, emaciated, and anæmic-looking. Had been twice married; ten years to second husband. Had two children by first husband, the second eleven years ago. For the last three or four years she had menstruated irregularly, sometimes missing three or four months, and last menstruated about Christmas, 1884. Since the end of February, 1885, she had been suffering from violent pains in the abdomen and back, with flatulence, morning retching, and vomiting. She had been attended for two months previously to seeing me for chronic inflammation of the womb, and had suffered from a purulent vaginal discharge for the last ten years, with pain over the sacrum, and dragging pains down the thighs. I found a smooth, rounded swelling occupying the hypogastric region, resembling about a fifth-month pregnancy. There were no intermittent contractions, and no movements to be felt on palpation. I could not hear any fœtal heart sounds, but there was a well-marked whizzing murmur heard all over the swelling, more distinctly over the left side. I found no marked vaginal changes or shortening or softening of the cervix uteri, and no abnormal bulging. I was unable to recognise the fundus uteri on bimanual examination. The breasts were slightly swollen and tender and the veins conspicuous, the areolæ being also darker than usual and somewhat swollen. I told the patient that she was probably pregnant and arranged to see her again in a month. Battley's opium solution in fifteen-minim doses greatly relieved the abdominal pains, and had to be continued in increasing doses, as she said that she could not exist without it. Three weeks afterwards she called to tell me that she had felt the child's movements. She had improved in her general health and appearance. The bladder and bowels continued normal. I did not examine her again until November. The movements had then ceased for about a month, though they had been very strong. She had slight metrorrhagia during the latter half of September. The abdomen was greatly distended and the superficial veins dilated. There was now marked fluctuation, and the usual physical signs of encysted fluid. No muscular contraction of the cyst-wall; no sound on auscultation. The cervix was not perceptibly altered, and the uterus appeared to be fixed by perimetritic adhesions. I indistinctly felt what I believed to be the limbs of a fœtus on gently manipulating the tender abdomen.

On Jan. 26th, 1886, I asked a friend to see the case, and he thought it was an ovarian tumour, with no fœtus inside or outside the uterus. I sent her next day to Dr. Frank

Digitized by Google

Nicholson of Hull, who kindly examined the case. He also suspected that it was ovarian cystic disease, and suggested tapping at once, and removal by abdominal section in a month if it filled up again. On the 31st she was admitted into the Grimsby Hospital. After using the catheter, I tapped her on Feb. 1st, and withdrew 101 ounces of dark, opaque, brownish-green coloured fluid, sp. gr. 1020. Microscopically it showed numerous leucocytes, granular débris, and large granular masses resembling the so-called granular ovarian cells described by Drysdale, and a few oil-globules. For the next fortnight she suffered from acute peritonitis, the temperature varying from 100° to 103° F., and was too ill to permit further examination. A severe attack of vomiting and diarrhœa followed, which was relieved by starch and opium injections. She rallied for a few days; the temperature became normal; but a slough now began to form through the abdominal walls a little below and to the right of the umbilicus, and she gradually sank and died on March 15th.

Necropsy, six hours after death.—There was great emaciation and an absence of subcutaneous fat. About four ounces of fetid purulent fluid escaped on opening the abdominal cavity, and the tumour was found to consist of a full-term, well-developed male child, placed abdomino-anterior, breech downwards, and in an advanced state of decomposition. The placenta was detached, and mostly absorbed. The sac presented a black appearance, and had undergone secondary inflammation and suppuration. The uterus was small, firmly fixed, quite empty, and its cavity measured two inches.

Remarks.—This case is interesting as showing the difficulty of diagnosis in such cases. Playfair says that "the diagnosis of abdominal gestation is by no means so easy as might be thought, and the most experienced practitioners have been mistaken with regard to it." Barnes, in his last work, says that "almost all the cases in which this form of gestation was suspected which have come under our observation turned out to be ovarian cysts."

AN INTERESTING CASE OF GALL-STONES, WITH NECROPSY.

BY ALBERT WILSON, M.D.

THE following case is of interest at the present time, when abdominal surgery offers such relief to cases of obstructed gall-ducts.

Mrs. B ——, aged sixty-five, first consulted me four years ago. She had for a long while experienced pain in the region of the gall-bladder, which had been treated as indigestion. On examination, I found below the tenth costal cartilage a large movable pear-shaped lump about three inches long, which could easily be grasped; it was the dilated gall-bladder. The stools being of normal colour, the obstruction would be in the cystic duct, and the hepatic and common ducts would be free. I treated her with large doses of belladonna, fomentations, and purging with podophyllin and colocynth. The result was that two gall-stones were passed (or rather found in the stools), also a large quantity of biliary gravel. The swelling and pain entirely disappeared, and therefore a cure seemed effected. The patient enjoyed good health for three years, when another similar but slighter attack came on, with distension of the gall-bladder, but it yielded to the same treatment. This time, though symptoms of stones were present, none were found, but much gravel was passed. Again, in January, 1886, she became ill. There was pain over the gall-bladder, which yielded to belladonna; vomiting was also present, but it resisted all the medicines employed, and yielded only to pancreatised food. There were no symptoms of gall-stones, and the gall-bladder could not be felt. She recovered so far as to be able to get downstairs for a few days, but again became ill, and died on Jan. 29th. Her death was not connected with the liver disease. She was extremely weak, the vomiting had returned, and two days before death curious convulsive clonic spasms set in, which seemed to cause death by exhaustion. As the nervous symptoms form a rare and interesting case of themselves, I shall briefly narrate them, especially as the cause was obscure. On January 28th, at 6 P.M., a fainting fit, with unconsciousness for a short period, ushered in the attack, although there had been occasionally throughout the day twitchings of the face and hands. After the faint the twitching set in all over the body: first an arm, then a leg, then the head, then the chest, would be jerked off the bed. On careful examination certain groups of muscles appeared to be affected; those at the back of the neck jerking the head back. The temporals, masseters, and sterno-mastoids, the muscles of the hyoid bone, jaw and tongue, were all in constant activity, tending to bite and jerk the thermometer out of the mouth, the deltoid and pectorals jerking the arm inwards. The biceps, the flexors, pronators, and opponent muscles of the thumb kept the hands and arms in constant motion. The flexors of the legs pointed the toes. Swallowing and speech were affected. She could only speak, and then with an effort, after the administration of amyl had relieved the spasms. Sensation and tendon reflex were diminished; ankle-clonus was absent; volitional power over the limbs was normal. She was quite conscious. The respiration and temperature were normal; the pulse was 140. There was retention of urine in the early stage; later on, the urine and stools were passed involuntarily. On Jan. 29th, the clonic spasms continued, but were feebler, the muscles being exhausted; those of the jaw and neck were the most active. She died during the night. Only an examination of the abdomen was permitted, so that the seat of the nervous lesion must remain a matter of speculation.

Necropsy.—Abdomen: The stomach was empty. The mucous membrane, which was coated with dirty-brown slime, was very congested, and covered with minute pin-point ecchymoses. Repeated attacks of peritonitis had matted together the duodenum with all the adjacent parts. What seemed to be the gall-bladder, but really proved to be an enormously dilated cystic duct, projected half an inch below the liver. I removed the whole mass, with part of the liver, for more thorough examination, and the result was very instructive. On opening the duodenum, the orifice of the common duct was easily found. It was dilated, and would easily admit my forefinger. Passing the finger up, I could feel bare gall-stones. On opening up the common duct, the hepatic duct was found normal in size. Passing to the cystic duct, I was amazed to find it dilated into one large cavity. This duct was dilated into a thin-walled cavity, three inches long and two inches wide, and contained eight large gall-stones with smooth polished facets. On further dissection, a slightly thickened ring indicated the dilated orifice of the gall-bladder. The gall-bladder formed a smaller cavity than that of the cystic duct. Its walls were slightly thickened, and it only contained five stones, one of which was in a distinct pouch at the most distal part. The whole dissection revealed how completely disorganised these parts get when gall-stones accumulate; and it is of great interest that the presenting part, instead of being the gall-bladder, was the cystic duct—a fact worth remembering for cases of operation.

The treatment I employed was belladonna in large doses to relax muscular spasm, and purges to excite reflex contraction of the gall-bladder to expel the stones. Two or three stones and much gravel were passed after the different attacks. The treatment, however, was only partially successful, for although many stones had been expelled from the gall-bladder, for want of sufficient *vis a tergo* some were retained in the dilated cystic duct. By operation the stones could have been very easily removed, as they were all so loosely arranged. The gall-bladder, being provided with muscular fibres, must have a slight expulsive force, which is probably excited reflexly by purgation. This process can be aided by relaxing the neck of the bladder and cystic duct by belladonna, chloral, or opium. The cystic duct has no muscular fibres, while its mucous membrane has several folds; it is, therefore, passive, and has no expulsive power, which accounts in this case for its great dilatation, and for the greater number of the gall-stones lying in it.

Leytonstone.

FOREIGN MEDICAL APPOINTMENTS.—Dr. Kosturin, of St. Petersburg, has been appointed Extraordinary Professor of General Pathology in the University of Kharkoff. Dr. Hans Virchow is to succeed Dr Hofmann in the charge of the anatomical instruction in the Berlin Academy of Art. Dr. Joseph Schröter has qualified as privat docent in the University of Breslau, with the view of cultivating especially the science of Bacteriology. Dr. Friedrich Korányi, Clinical Professor in the University of Buda Pesth, has been appointed Rector for the ensuing academical year.

ST. GEORGE'S HOSPITAL.

THREE CASES OF PYÆMIA, ENDING FATALLY; NECROPSIES; REMARKS.

(Under the care respectively of Drs. CAVAFY, WHIPHAM, and DICKINSON.)

THE following cases present some points of interest when grouped together. It is not very common to meet with three cases of pyæmia in which no cause for the disease can be found, either during life or post mortem, within six weeks, in the practice of one hospital. The disease appears to have been idiopathic, and it is difficult to say in what way the germs of the disease found entrance to the system. The diagnosis in no case appears to have been difficult, but in the second the occupation of the patient and the presence of the pustular eruption evidently caused inquiries to be instituted with the idea of carefully excluding glanders. We are indebted for the following notes to Dr. Griffiths, medical registrar.

CASE 1. Victor H——, admitted May 9th, 1885, under the care of Dr. Cavafy, was a healthy lad of fifteen, who had had no previous illness, and had no cut, abrasion, or sore within twelve months of the commencement of the illness. He had two cold swimming-baths within seven and ten days respectively of admission, but he felt no ill effects and had no rigors; but on May 5th he had acute pains in the legs, with rigors, and then "pains all over." When admitted he had a temperature of 101°, a coated tongue, quick pulse, and patchy redness round the right wrist and elbow, over the right leg and ankle-joint, and some effusion into the left knee. He had no cardiac murmur. There were some dulness and harsh breathing at the base of the right lung, and high-coloured urine, with one-fourth albumen. He became delirious on the third day, with much swelling round the great toe joints and in the third joint of the first finger. On the fifth day his temperature fell to normal, but rose steadily afterwards, remaining at 103° for two days, and rising to 105·4° just before death. He was noisy at night, his tongue became dry and brown, his respiration rate reached 50, and pus was found in the inflamed joints of the toes, with small collections of pus in the right forearm and in the inflamed joint on the right hand. He was unconscious for forty-eight hours before death. No diarrhœa or abdominal symptoms, and no pulmonary complications beyond those associated with high temperature and a recumbent position, were present. Salicylate of soda in large doses had no effect on the temperature. Death occurred on the thirteenth day.

Necropsy, sixteen hours after death.—The blood was very fluid, staining the endocardial lining. There was pus in the right wrist-joint, in the second joints of both great toes, and purulent fluid in the right hip-joint, with a small collection of pus in the substance of the left tibialis anticus muscle, and in the middle of the right forearm. There were numerous small deposits in the lungs of various sizes from a pea to a walnut, and in both kidneys very small deposits, but none in other viscera, which were apparently healthy. No erosion of bone surfaces or other lesions were found.

CASE 2.—Wm. F——, aged thirty-two, was admitted on April 3rd, 1886, under the care of Dr. Whipham. The patient was a stableman, a moderate beer-drinker, who had had no injury of any kind, nor were any of the horses under his charge ill in any way. Beyond the fact that he had had acute rheumatism five years previously, he had "enjoyed the best of health," and did his work up to the date of admission. He had been ailing for fourteen days in an obscure manner with headache; diarrhœa set in thirty-six hours before admission, but there were no signs or pains, and only an extremely slight dry cough. He was a powerfully built man, with a high temperature, but clean tongue; pulse small, 88, and no dyspnœa. He presented much tremor of the hands and tongue. His cardiac action was unimpaired and sounds free from murmur, and, with the exception of mucous râles at the base of the right lung, with rhonchi over both sides, there was nothing to be heard over the thorax. No abdominal symptoms and no enlargement of abdominal viscera. Urine, concentrated, specific gravity 1030, with a faint trace of albumen and some excess of urea. He sweated profusely, had no acid smell about him, and his expectoration was bronchitic. On the third day he presented breathing of a tubular character in the right midscapular region, and his expectoration became rusty-coloured. Diarrhœa set in again on the fifth day after admission, the stools being loose and light, but there were no spots on the abdomen. His pulse and respiration rate, however, increased from this point, though the former was usually 110 and the latter 30. He became delirious on the tenth day, with increased tremor of hands, distended abdomen, and ten loose motions; and on the eleventh day numerous small pustules came out on the thorax, face, and shoulders, a few on the thighs, but none on the abdomen. He had acute inflammation round the right ankle-joint and the third joint of the third right finger, with a sweet smell in the breath, a dry tongue, and pulse of 128, with respiration of 60. He passed into delirium with subsultus tendinum. Fresh crops of pustules made their appearance, running a rapid course, with two small collections of pus over the middle of each tibia on its outer aspect. He died on the thirteenth day after admission, and on the twenty-seventh day after his first feeling of illness. He was treated with expectorants, stimulants, and a grain each of calomel and opium at night. The temperature chart showed a gradual evening rise from April 3rd, when it was 102·6°, to April 13th, when it reached 105·8°, there being a morning remission of from one to three degrees.

Necropsy, sixteen and a half hours after death.—The blood was fluid. There was a small collection of pus over the outer aspect of the middle third of each leg. There was no other purulent material to be found, and no deposits in lungs, liver, spleen, or kidneys, and no intestinal lesions or lesions of bone.

CASE 3.—Charles H——, aged fifty-three, was an old soldier of thirty years' service, who had been employed in a draughty picture-gallery. He had had no previous illness, except an injury to the head some five years before. He had complained of malaise for one month, with no definite symptoms, but did his work up to twenty-three days before admission, when he left off work owing to a slight cough and a boil on the right hip, which yielded readily to poulticing. He became strange in manner, and for six days prior to admission had been delirious. There had been slight diarrhœa set up by purgatives for four days, but he had had no rigors, nor had he complained of sore-throat. Nor, with the exception of a corn which he was in the habit of cutting on Sundays, was there any abrasion, wound, or injury. He was admitted, under the care of Dr. Dickinson, on April 22nd, 1886, with a temperature of 103°, a dry, leathery tongue, pulse 112, slightly dicrotous, and with respirations of 48. He was in a state of semi-collapse, with tremors of hands and slight subsultus tendinum. There were several small boils on his legs, with one large-sized collection of pus on the forehead; patchy redness over the dorsum of the left foot, round the right ankle-joint, and outer side of knee-joint, with some effusion into both knee-joints. His urine was lithatic, sp. gr. 1025, with a cloud of albumen on boiling. Heart's sounds were weak, but free from murmur. Lungs: Wheezing rhonchi with coarse râles on both sides, and at the right base dulness with weak breathing, fine moist sounds, and diminished vocal resonance. Abdomen tumefied, but exhibiting no eruption and no enlargement of abdominal viscera. This was readily recognised as a case of pyæmia, and treated with stimulants (eight ounces of brandy and eighteen grains of quinine daily). He exhibited next day a number of small vesicles, which became pustular quickly, and the pulse rate and respiration rate quickened, while he became delirious—delirium of a low muttering kind, with subsultus and busy movements of the hands. He passed two black liquid stools and the albumen in his urine increased slightly in amount, the urea being 2·2 per cent. and the specific gravity 1025. He slept scarcely at all, and on the fourth day became profoundly delirious, while fresh successive crops of rapidly-forming pustules made their appearance on the body and face. Patchy redness spread over the

Digitized by Google

third joint of the middle finger of each hand, and his temperature rose to 104·4°, the maximum during his illness. From this point he sank, his temperature remaining at 104°. There was floccitatio and busy delirium, ending in death on the fifth day after admission, successive pustules appearing and maturing within two hours. He passed only the two motions mentioned, took food fairly well up to the last twenty-four hours, and presented no additional symptoms.

Necropsy, twenty-nine hours after death.—The body was well nourished. Numerous small abscesses were found—one on the centre of the forehead, others on the outer side of the upper third of the legs and front of the right thigh. There was purulent fluid in both knee-joints; a small hard uninflamed corn on the right foot. The lungs exhibited patches of deep congestion freely scattered throughout, but mostly affecting the apex of the right and the base of the left lung, but showing no tendency to breaking down. There was nothing abnormal in the liver, spleen, kidneys, or intestines, or in any bones. Ulceration of the left tonsil, of a recent character, was shown to have existed.

Remarks.—These three cases belong to a large class, in which no apparent injury can be found after death; the ulceration of the tonsil in the last case being of very recent date, supervening in the course of the illness. That pyæmia is capable of arising idiopathically is denied by many; and in cases of recovery the cause is attributed to some superficial ulceration, or slight inflammation of bone or periosteum. But cases in which a careful post-mortem examination has been made, with negative results, seem to point to the possibility of such idiopathic origin.

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

TWO CASES OF ILEUS, OCCURRING IN BROTHERS; EMPLOYMENT OF TOBACCO; RECOVERY; REMARKS.

(Under the care of Dr. CAMERON.)

CASE 1.—J. D——, aged twenty-two, was admitted on Jan. 26th, 1885. His previous health had been unexceptional, and his present illness dated from the 19th, when, whilst working with an axe in a stooping position, he was seized with sudden pain in the abdomen, which necessitated his giving up his work—that of block-making—and going home. Vomiting commenced the next day, and continued at intervals up to admission. He thought he had kept down little or no food during the week, but the amount of pain had on the whole been inconsiderable. Purgatives and injections were, he said, freely administered to him before admission; but there had been total constipation since the date of his attack, with the slight exception that one injection given three days before coming to the hospital produced a very slight motion; and since the constipation began he thought he had passed no flatus. His bowels had previously been quite regular, acting daily, and no irregularity in his diet could be fixed upon, unless it was that he had eaten half a pound of pork for dinner on the 17th. He had been strictly temperate.

On admission, the signs were chiefly negative, and nothing was made out by examining the abdomen, except a little tenderness in the epigastric region. The rectum was empty. The temperature was subnormal, and the pulse 80; tongue clean and moist; and the patient did not seem at all ill. Shortly after admission he vomited some green bilious fluid. He was ordered five minims of tincture of belladonna every three hours, a mustard poultice to be applied to the abdomen, and to have a limited amount of food.

Jan. 27th.—Patient comfortable; pulse 72; rather hungry and very thirsty. Has had seven ounces of gruel and seven ounces of milk since admission. The belladonna was lessened.

28th.—Food given: seven ounces and a half of milk and an equal quantity of gruel. Vomited fourteen times in nineteen hours, always of the same character, green bilious fluid, and very little at a time. Urine contains bile; specific gravity 1034. His symptoms being so mild, the pulse 80, the temperature 97°, and the patient in no discomfort, it was determined to try the effect of purgatives, and he was ordered early in the day six grains of calomel in two pills, to be followed by one ounce of white mixture every two hours, and the two pills were repeated in the evening.

29th.—Food given: five ounces and a half of milk and four ounces and a half of gruel. Has had four pills and ten ounces of the white mixture. Abdomen more tense and uncomfortable; no tenderness; a little pain. Some hiccough. No action from bowels, and no flatus passed. Vomiting, which had been absent since the previous morning, returned during the afternoon, six times altogether; character as before. General condition much the same. Pulse 84; temperature 97°. In view of the urgent symptoms that might at any time arise, a consultation was held, at which it was decided that at present there was not sufficient reason for any operative interference. The purgative treatment, having been fairly tried, was discontinued, and he was ordered hypodermic injections of morphia, one-sixth of a grain to be given at intervals, according to circumstances. A simple enema was tried without result.

30th.—Food given: two ounces and a half of milk, three ounces and a half of gruel, and two ounces and a half of beef-tea. At a consultation the same opinion was again expressed. He was ordered a tobacco poultice to the abdomen; to have no more food, a little ice only. Vomited occasionally during the day, and in the evening was given an enema of tobacco—ten grains in half a pint. This was repeated during the night.

31st.—This morning he feels a great deal more comfortable. Pulse 84. Tongue rather dry. Abdominal signs quite negative; no pain. Has had no food and is very hungry. No action from the bowels. Passed flatus twice (?) The tobacco appears to have had a soporific effect; he has slept much more since it was employed. Another tobacco poultice was applied to the abdomen, and the tobacco enema repeated. All three injections were retained.

Feb. 1st.—Temperature subnormal. Pulse 100. Has had no food. Vomited once, with return of pain at the same time, more severe than before. No more flatus passed. Ordered another tobacco injection, which produced some faintness, though returned almost immediately. Patient does not smoke or chew. The morphia injections were continued, but in the evening he was "very uncomfortable," and the pulse was 100. He was ordered a little brandy, at the rate of an ounce and a half in twenty-four hours.

2nd.—Passing flatus freely since about 3 A.M. Bowels acted in the afternoon; motion semi-solid. Allowed a little liquid food once in two hours.

4th.—Bowels have acted four times since. Ordinary milk diet.

6th.—Bowels not open again. Given half an ounce of castor oil, after which they acted twice. Diet increased.

10th.—Bowels acting once a day; stools rather loose; never passed any scybalæ. Discharged well.

CASE 2.—T. D——, aged twenty-nine, who has been subject to attacks of constipation for about three years, and has frequently had to take purgatives, was admitted on March 27th, 1886. Eighteen months ago, having been then constipated twelve days in spite of purgatives and injections, the patient was admitted into this hospital, and was ordered a large enema of soap-and-water; after which the bowels immediately acted freely, and he was discharged after a day or two. He again became constipated a week afterwards, but was relieved by a purgative. He is very temperate, and does not smoke or chew tobacco; his occupation is that of scraping ships, often having to work in cramped and constrained positions and in a very small space. His bowels had been acting regularly up to the 18th, when he began to feel pain in the right iliac region. The bowels acted again on the 20th and on the 22nd, on which evening the pain became more severe, and he took a purgative. He vomited frequently next day, and subsequently at intervals up to admission. The bowels only acted once—very slightly—since the 22nd, though he took several doses of jalap, castor oil, &c.

When admitted he said he had severe pain in the left side of the abdomen and in the epigastrium. The general signs were all negative; pulse and temperature normal. He was ordered an enema with one ounce of turpentine, one ounce of white mixture three times a day, and low diet.

March 28th.—Pulse and temperature normal. The bowels acted very slightly after the injection. Has vomited once. Says he still has the pain, but that it is not so severe. Injection repeated with one ounce of castor oil.

29th.—Temperature morning and evening 99°; pulse 88. Has vomited once. Bowels not acted. The pain is said to be worse to-day, and the abdomen tender. Examination reveals nothing. To have nothing by the mouth except ice. A tobacco poultice to be applied to the abdomen.

March 30th.—Temperature 99·6°; pulse 92. No further vomiting. The poultice "took away the pain instantly."

Digitized by Google

Passing flatus freely, which he had not done for some days. Allowed a teaspoonful of Brand's essence about once in three hours. The poultice to be repeated.

31st.—Pulse and temperature normal. Flatus still being passed, but the bowels have not acted. To get up for a little in the afternoon.

April 1st.—Feels quite well; fæces felt in rectum and a simple enema ordered, after which the bowels acted freely.

3rd.—Bowels have acted three times since. No scybalæ passed.

5th.—Discharged well.

Remarks by Dr. CAMERON.—The duration of the sudden and complete constipation in the first case—fourteen days—is worthy of notice, as during this time no very urgent, as distinct from anxious and serious, symptoms arose. The temperature was always subnormal; the pulse only once reached 100. The vomit never became stercoraceous, nor did the patient ever seem really and acutely ill. In both instances, the symptoms being so mild and the signs so negative, it was decided to try the effect of purgatives; but failing in their object they were stopped, as only likely to do harm, whilst the benefit derived from the subsequent employment of tobacco was very marked. It will be seen that the amount of food at first allowed in Case 1 was extremely limited; possibly the effect of afterwards withholding it altogether was beneficial. The difficulty of diagnosing with certainty the exact cause of an intestinal obstruction was here fully exemplified; in both cases, though symptoms were present, physical signs were conspicuous by their absence. Perhaps the attitude and occupation of the first patient at the time of his sudden seizure may have produced a temporary twist, which left for a time a complete paralysis of the bowel; and in the second case, the occupation may have been a factor in producing the attack under notice, and the previous minor attacks of apparently simple constipation to which he had been subject. The cases are also interesting as having occurred in brothers.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Foreign Bodies.—Cholesterine in Detached Retina.—Exophthalmic Goitre.—Detachment of Retina.—Embolism of Central Artery in Puerperal Septicæmia.—Cataract Extraction.

AN ordinary meeting of this Society was held on the 10th inst., Mr. Jonathan Hutchinson, President, in the chair.

Mr. BRUDENELL CARTER related a case in which a fragment of the edge of a steel chisel had been harmlessly embedded in the sclera of the right eye for fifty weeks; the chip had entered one line from the cornea on the outer and lower side, and had gone directly backward, and could be seen embedded in the choroid or sclera, and surrounded by a few small blood-clots. The eye was kept under the influence of atropine; the chip became coated with lymph; the blood-clots underwent absorption, and vision returned to the normal. All congestion had disappeared in three weeks, when the patient returned to his work as a carpenter. Central vision was unimpaired, and the blind spot, due to the fragment, could be found with difficulty.—The PRESIDENT had known of cases of foreign bodies about the eye in which no irritation had ensued.—Mr. SIMEON SNELL referred to three cases read before the Society last October, and also to another in which a piece of steel lying above the optic disc was detected, but there was no sign of its mode of entrance.—Mr. BRUDENELL CARTER spoke of a case of dark amber-coloured cataract in one eye which was extracted; in its centre a small dark fragment of iron was detected, but there was no sign of how it got there; the man had been present at the explosion of a boiler, but was unaware of any accident to his eye.

Mr. SIMEON SNELL (Sheffield) related the case of a boy, aged eleven, who had been blind with the right eye since about three years of age. When seen in the early part of 1886, the retina was detached, opaque, and thickened, but more so in some parts than in others. Cholesterine-plates were studded over the retina, chiefly on the inner side; these were visible to the naked eye, but much better with focal illumination or the mirror. The retina was nearly universally detached, and only at the periphery outwards was a slight glimpse of indistinct red reflex obtained. The character of the subretinal fluid could not be made out. The left eye had a high degree of hypermetropia (8 D), but was otherwise normal. Mr. Snell remarked on the presence of cholesterine, which had been observed in most parts of the interior of the globe.—Mr. NETTLESHIP did not know which Mr. Snell considered the more important, the presence of crystals of cholesterine or the detachment of the retina in so young a patient. Detachment of the retina in children was probably not of very rare occurrence, though it was difficult frequently to ascertain the cause. He remembered to have examined an eye, when curator at Moorfields, that showed a large detachment with patches of white appearance thereon, and also a kind of whitish sediment, probably of a fatty nature; scarlet fever was the probable cause in this case.—Dr. BRAILEY considered that detachment of the retina in children was not very uncommon; they constituted a form of pseudo-glioma; in cases where hæmorrhage had occurred the intra-ocular tension was increased, and this separated one form of pseudo-glioma from others. These cases, however, were not of quite the same kind as that referred to by Mr. Snell. In reply to Mr. Nettleship, he said that there was no evidence of iritis in the cases alluded to.

A paper on Exophthalmic Goitre, by Mr. W. O. MAHER of Melbourne, Australia, was read by the Honorary Secretary (Dr. W. A. BRAILEY). It related a case of exophthalmic goitre, with unilateral exophthalmos, occurring in a man aged thirty-four. Exophthalmos had been noticed by the patient a year before he applied for treatment; palpitation had been present for three years; the thyroid gland was found to be notably enlarged, especially on the right side, and the exophthalmos was present on the same side, the right cornea being 2·5 millimetres to 3 millimetres in advance of the left. Von Graefe's symptom was absent.

Mr. MAHER also contributed a case of Total Detachment of the Retina in a boy aged eight. The child had had a squint divergent for four years before he came under observation. The pupil did not react directly to light, and but slightly indirect; extending across the retina at the upper part was a thin band of organised lymph. Vision was so defective that there was not even perception of light. The mother was confident that the child had never received any blow on the eye, and that the only injury the eye could have received was at birth, when the forceps was used. The presence of the band of lymph in the retina was thought to point to the detachment being of traumatic origin; and, as complete congenital detachment of the retina was probably unknown, Mr. Maher was inclined to think that the detachment was probably due to injury inflicted by the forceps.

Mr. SIMEON SNELL related a case of Embolism of the Central Artery occurring in a young woman aged twenty-six. After the birth of her first child, on November 19th, 1885, she was much neglected by the midwife, and was not kept clean. Four days later rigors commenced and symptoms of septicæmia developed. The pulse was 120, and the temperature 103° F. The medical man called in thought the condition very grave at first. During the night of Nov. 27th sight was suddenly lost in the left eye. She gradually recovered from the septicæmic state, but vision remained lost, and when first seen by Mr. Snell in January, 1886 (two months after the attack), the appearances in the fundus were those of embolism of the arteria centralis retinæ in a late stage. There was no cardiac disease. The interest of the case lay in its association with puerperal septicæmia. In the puerperal state, and in the feeble condition of the patient, simple thrombosis of the heart or pulmonary vessels could easily have occurred, and might have been the source of embolism. The source of the embolus was doubtful, but he wished to record the fact of the occurrence of embolism of the central artery of the retina in septicæmia, and that its course was not attended with any unusual or inflammatory effects.—Mr. NETTLESHIP asked whether there was not more hæmorrhage and haziness of the retina than usually obtained in embolism.—Dr. S. MACKENZIE had not seen a case of embolism of the central artery of the retina in relation with pregnancy or the puerperal state.—Dr. J. ANDERSON thought that pregnancy was a predisposing cause of embolism of the left middle cerebral artery, which was very prone to occur when mitral stenosis and pregnancy were combined.

A paper by Dr. DYCE DAVIDSON (of Aberdeen), relating a

Digitized by Google

case of Meningitis after Enucleation, was read by Dr. STEPHEN MACKENZIE. The patient, a woman aged forty-nine, had received an injury to the right eye four or five years before the enucleation was performed; the eye had been quiescent for three years until three weeks before she applied for treatment. She was impoverished, ill-nourished, and broken down in health, but presented no signs of any disease. The urine did not contain albumen. The eye, which was painful and tender in the ciliary region, was enucleated three days after admission, antiseptic precautions being used, and a salicylic pad applied. Twenty-four hours later she was in a high fever, had vertical headache and a foul tongue, but the wound was healthy. She died comatose on the third day. The wound looked œdematous at the time of death. At the necropsy meningeal inflammation with redness of the optic nerve and œdema of the orbit were observed. All the other organs were healthy except the uterus, which was in a condition of catarrhal inflammation. Dr. Davidson suggested that the case was one of pyæmia started by this condition of the uterus, and surmised that this suggestion might explain other cases.—Dr. BRAILEY wished for further information as to the salicylic pad, as he thought there were important variations in treatment with regard to the use of pads.—The PRESIDENT said he had enucleated over and over again during the acute stage of suppuration, but had never had a case of meningitis.—Mr. NETTLESHIP said that half the cases had occurred in males, and thought it was unnecessary to look to the uterus for a source of septic infection.—Mr. WAREN TAY considered that further information as to the nature of the meningitis and the state of the optic nerve (which was not usually affected) ought to be obtained.

Mr. BRUDENELL CARTER read a paper on some Practical Points connected with Cataract Extraction. He commenced by referring to a paper by Mr. Critchett, dealing with certain improvements of detail on which further progress in cataract extraction must chiefly depend. Mr. Carter expressed his concurrence in Mr. Critchett's remarks about the spring speculum, the entire abandonment of which he had himself advocated in a note added in the beginning of 1885 to the still unsold copies of his Lettsomian Lectures. He did not, however, approve of Mr. Critchett's suggestion to use the third finger of the fixing hand as a lid-elevator, preferring the elevator of Noyes in the hands of a careful assistant. He thought that Mr. Critchett's method unduly restricted both the choice of a fixing point and also the mobility of the fixing hand; and he condemned the oblique section which these restraints rendered necessary, on account of its tendency to expose the coloboma iridis, and to produce astigmatism along an oblique corneal meridian. He referred to the application of antiseptic surgery to operations on the eyes, and advocated the use of a solution of cocaine and of salicylic acid. Dr. Galezowski's dressing of specially prepared gelatine had not been successful in his hands; and he recommended a compress of wet cotton-wool, placed over a morsel of linen smeared with sanitas vaseline, and retained by a strip of knitted cotton, this being secured by three pairs of strings. As among trifles contributory to perfection, he attached much importance to this method of dressing.—Mr. ANDERSON CRITCHETT defended the use of the finger in the place of the speculum, because he found it best to make fixation just below the point of counter-puncture. The old French toothed forceps used to tear the conjunctiva; he had found the double fixation hook answer well in some cases; but the best instrument was a slight modification of the forceps used by Dr. Bell Taylor; with this instrument, a few fibres of the sclerotic could be pinched up, and a firm hold got upon the eye at any point. Holding the eye at the point where the counter-puncture was to be made, the section could be made of any size. It was impossible for the assistant to work in perfect harmony with the operator, and time might be lost. Where the operator depended entirely upon himself, the commencement of a spasm could be felt, and the finger relaxed. In completing the section, the finger was withdrawn, the lid closed gently, and there was thus less chance of the lids being squeezed together. With cocaine the patient had less control over the lid, and the danger of a squeeze was greater. With regard to the oblique incision, he was in the habit of making his puncture very little below the centre of the pupil, and it was not necessary, as a rule, to remove more than the central portion of the iris. He had not suggested that it was desirable to cut out with one push; three-fourths of the incision might be made with the push, and the remainder in withdrawing. The knife he used was curved, had a central point, and commenced to bulge immediately below, so that, with a steady onward push, it cut its way so far as to complete three-fourths of the section. He referred to the case of an old man, aged eighty-four, in whom he had operated on both eyes simultaneously. In the one eye he had made the incision entirely in the sclerotic; in the other he had made it entirely in the cornea. In this he had followed a dictum of his late father, who had always taught that, in operating on both eyes simultaneously, it was always right to give the patient every chance by choosing a different operation for each eye. M. Galezowski, who was present at the operation, provided some of his gelatine discs, which he stated he had used in 107 consecutive cases without a single case of suppuration. In this case, unfortunately, the eye in which the incision was confined to the cornea suppurated with remarkable rapidity; the other eye did very well, and sight was good. The case illustrated the wisdom of the late Mr. Crichett's dictum: if the incision had been made in the cornea in both eyes, probably both would have been lost.—Mr. NETTLESHIP commented on the very strong solutions of cocaine used by Mr. Carter. He agreed with those who believed such a custom to be dangerous, and used a 2 per cent. solution. He thought the exact direction of the incision was of small consequence; the incision directly upwards gave the best cosmetic results. Liebreich always made his section downwards entirely in the cornea, and never used a speculum; in his hands the results were good on the whole.—Mr. MCHARDY suggested that it was advisable to put a drop of cocaine in the eye not to be operated on; spasm was less liable to occur when this was done.—Mr. HODGES (of Leicester) had performed Mr. Critchett's operation in several cases, but only in one case without the speculum. He had been exceedingly pleased with the ease with which the operation could be performed and with the final result.—Mr. BRUDENELL CARTER, in reply, said that he had not met with the tendency to spasm with the frequency Mr. Critchett inferred. For fixing, he preferred a pair of forceps with a broad flat point, and with at least three or four teeth. The advantages of the meridional fixing point were considerable, and he thought it important to have freedom of movement in the fixing hand. The cocaine solution contained salicylic acid; it was thus antiseptic, and it had the advantage that in washing the eye the cocaine was not all washed away.

The following living and card specimens were exhibited:—Mr. W. P. Kiall (Bristol): A boy in whom Evisceration of the Eyeball was performed, and a hollow silver ball introduced; the boy had subsequently received a blow, followed by a "black eye," but without any other consequence. Mr. W. Lang: A young woman in whom Evisceration was performed, and a glass ball inserted in the manner recommended by Mr. Mules; a glass eye had been fitted, and the movements were fairly good. Mr. S. Snell: A Stamp for indicating Axes of Cylindrical Lens. Mr. J. B. Lawford: New Tissue formation in Choroid (and Retina?) following injury, probably rupture of choroid. Mr. Marcus Gunn: A woman who had presented for many years symptoms of Tabes Dorsalis and Exophthalmic Goitre, in whom marked pigmentation (? Addison's disease) had recently developed.

OBSTETRICAL SOCIETY OF LONDON.

Artificial production of so-called Lymphatic Varix.—Causes of Difficulty in Turning.—Spurious Hermaphroditism.

A MEETING of the above Society was held on June 2nd, Dr. Potter, President, in the chair.

The following specimens were shown:—Dr. John Phillips: Fibroids in Twin Pregnancy. Dr. Herman: Fœtus and Placenta from Extra-uterine Gestation, removed by Abdominal Section. Mr. Knowsley Thornton: Ovarian Tumour and Fibro-myoma Uteri removed at the same operation.

Dr. F. H. CHAMPNEYS read a paper on the Artificial Production of so-called Lymphatic Varix. The object of the author was to determine whether so-called lymphatic varices could not be produced at will by the simple expedient of cupping striæ in the skin which were not œdematous. If this produced appearances which could not be distinguished from so-called lymphatic varices, it would tend to prove that these are really due to general lymphatic œdema, showing most plainly over the least supported parts of the

Digitized by Google

skin, and not to any peculiar arrangement of lymphatics or to obstruction of any particular lymphatic trunks. This was proved to be the case. The author concludes that lymphatic varix is a misleading expression.—Dr. HERMAN said that Dr. Champneys had spoken in his paper of lymphatic œdema and of œdema in his remarks. He asked whether this alternative mode of expression was simply for brevity, or whether it illustrated his view as to the nature of the fluid filling the cracks. He believed, with many others, that in phlegmasia dolens there was not simply œdema from venous obstruction, but there was obstruction in the lymphatic system of the limb. There was little direct proof of this, but there were strong arguments from analogy in its favour. Dr. M. Duncan's case was important, for if the fluid in the varicose skin cracks were lymph, it furnished some direct evidence that there was obstruction to the return of the lymph from the limb. Did Dr. Champneys consider that his experiments had any bearing on this question? When he spoke of œdema, did he mean the swelling that resulted from altered pressure-relations in the capillaries or did he mean by "lymphatic œdema" that the fluid had been exuded from the lymphatic vessels?—Dr. M. HANDFIELD-JONES called Dr. Champneys' attention to three cases of dilatation of lymphatic radicles which were in St. Mary's Hospital and were published in THE LANCET, Aug. 7th, 1875. They closely resembled that of Dr. M. Duncan. Mere œdema was not sufficient to produce the appearances described. Some active pathological condition attacked the small spaces from which the lymphatic vessels started and spread from thence along the larger canals. It was noteworthy that, considering the frequency of œdema of the lower limbs, the appearances described in the cases referred to were rare.—Dr. CHAMPNEYS said his paper was an argument that the so-called "lymphatic œdema" was not a special affection of lymphatic vessels, but was merely a general œdema showing most plainly at the weakest parts of the skin. In reply to Dr. Herman, Dr. Champneys said he meant ordinary œdema, and not any special affection of the lymphatic vessels.

Dr. G. ERNEST HERMAN read a note on one of the Causes of Difficulty in Turning, with remarks on the Practice of Amputating the Procident Arm. The author describes difficulty in turning due to impaction of the point of the shoulder below the imperfectly dilated internal os. In these cases there is no great difficulty in seizing the lower extremity, but when this has been done the condition described prevents the child from rotating. The proper way to overcome the difficulty is to press the point of the shoulder towards the middle line of the cervical canal, and thus disengage and raise the shoulder. When this is done the child is easily turned. The author then refers to the writings of those who have advocated amputation of the arm in cases of transverse presentation which cannot be turned, on the ground that turning becomes easy when this has been done. He believes that these cases were of the kind now described by him, and that the amputation of the arm was effective by removing the resistance offered by the impacted shoulder. But he did not think amputation of the arm was proper in such cases, for the child could be turned if the point of the shoulder was disengaged in the manner he had described, and if the child were dead, decapitation was better than amputation of the arm followed by turning.—Dr. GALABIN did not think that the internal os could prevent the shoulder being pushed upwards. It might, however, prevent its ascent when the attempt was made to turn as described by Dr. Herman, by acting on both poles of the fœtus at once, for this would move the shoulders not only upwards but also outwards, and it would be more likely to be resisted by the projecting ring. He had never had occasion either to cut off the arm or push the shoulder; and he had only once met with a case in which it was impossible to turn, and he had to decapitate. In this case a shoulder had been mistaken for a breech, and expectant treatment continued for two days. He believed that there was no case in the records of the Guy's Hospital charity in which turning was impossible and alternative embryotomy became necessary. Where it was necessary to act on both poles of the fœtus, he would make the action alternately, pulling down a leg and pushing up a shoulder. He asked if Dr. Herman had been always successful with his method, or whether embryotomy was still necessary sometimes.—Drs. Boxall, Champneys, Playfair, Cleveland, and the President also made remarks. — Dr. HERMAN, in reply, said that he did not assert that the condition described in his paper was the cause of difficulty in every case, but that, on the contrary, he thought it an occasional and rare source of difficulty. There was in these cases little difficulty in bringing down the foot, but much in turning the child; while where the uterus was contracted tonically round the child there was difficulty in seizing the foot. He agreed with Dr. Galabin, and had pointed out in his paper that the difficulty was augmented by pushing up the shoulder while pulling down the leg. The defined swelling of the shoulder which was present showed that it had been encircled for a long time. He had felt the contracted ring above the shoulder. He adopted in turning the plan advocated before the Society in a valuable paper by Dr. Galabin—i.e., he seized the most easily accessible foot. Attempts at turning had been made under anæsthesia in one of his cases for three-quarters of an hour; in the second anæsthesia was not employed; and he did not remember as to the third.

Dr. JOHN PHILLIPS read a paper on four cases of Spurious Hermaphroditism in one family. The author gave the family history. Out of nine pregnancies, the 3rd, 6th, 8th, and 9th were hermaphrodites. Fright during the third month of pregnancy in the mother's opinion caused the first. None of them survived more than a few days, and the author had an opportunity of post-mortem examination. He laid the results before the Society with all the more important parts dissected out. The family antecedents were very carefully gone into, many of them being personally examined. Several defects, such as hernia and the like, had been discovered. A genealogical tree was appended. The author gave a historical review of the whole subject. There appeared two causes at work on the mother's side in the production of this deformity: 1. The initial fright which she received when pregnant with the first. 2. The continued dread and mental distress which ensued on her bearing a deformed child. Conclusions: 1. A hernial or other weakness present in one parent acting as a predisposing cause, any deep maternal impression received about the third month might induce some impediment to the proper differentiation of the uro-genital system. 2. That a distinct tendency towards bearing hermaphrodites might be developed in a mother who had already borne one.—Dr. M. HANDFIELD-JONES asked as to the relative frequency of sterility in these spurious hermaphrodites. It was a law of evolution that in hermaphrodites one set of organs atrophied in proportion to the development of the other, and so in cases with a large clitoris imperfect uterus and ovaries might be expected.—Dr. CLEVELAND mentioned that he had a patient with only one testicle descended, who was the father of a large family, none of whom were deformed.—Drs. John Williams, Willcox, Champneys, and Galabin also made remarks.—Dr. JOHN PHILLIPS, in reply, said that he thought specimens of spurious male or female hermaphroditism were not uncommon, but that four in one family was unique. The father was the elder of the two parents, but his exact age he could not remember. He could not throw any light on Dr. Handfield-Jones's queries.

Reviews and Notices of Books.

Manual of Operative Surgery. By W. ARBUTHNOT LANE, M.B., M.S., F.R.C.S., Senior Demonstrator of Anatomy, Guy's Hospital; Assistant Surgeon to the Hospital for Sick Children. London: George Bell and Sons. 1886.

A Manual of Operative Surgery. By LEWIS A. STIMSON, B.A., M.D., Surgeon to the Presbyterian and Bellevue Hospitals, Professor of Clinical Surgery in the Medical Faculty of the University of the City of New York, &c. Second Edition. With 342 Illustrations. London: H. K. Lewis. 1886.

FROM the plan and scope of Mr. Lane's work we infer that the author has not aimed at teaching his readers how to operate, but rather how they may answer satisfactorily the routine questions on operations which are set at written examinations. The book is certainly convenient from this point of view. The conduct of an operation is divided into distinct steps, which are duly numbered, and the parts cut through in each incision are clearly and accurately stated. The operations are described after the plan generally adopted in manuals of dissection, and the book impresses us as being

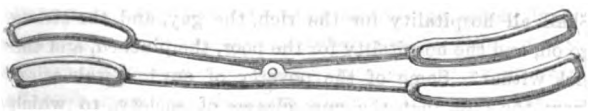
Digitized by Google

written from the anatomical teacher's point of view. We have noticed a few errors which have escaped the eye of Mr. Lane in revising the proofs. Thus, in the description of gastrostomy no mention is made of the side of the body on which the operation is to be performed. A few pages further on Mr. Golding Bird's case of jejunostomy is stated to have been the first performed in England, while in the very journal to which Mr. Lane refers his readers for an account of this case mention is made of an earlier case in London. The abdominal incision through the linea semilunaris is twice spoken of as "Langenbeck's," and nowhere do we find it correctly called Langenbuch's. On page 204 the reader is told that the second step of the operation for division of the tibialis posticus tendon is to "enter the point of a sharp-pointed tenotomy knife between the tibia and the tendo-Achilles." We notice that in his instructions for the operative treatment of empyema Mr. Lane lays considerable stress upon an opening being made into the lowest part of the cavity; in this he differs from several recent writers on this point, who are able to adduce cogent reasons in support of their view. There are cases, however, and we have seen such, where an opening at the most dependent part appears to be essential to cure. The book is illustrated with several copies in outline of the plates in Braune's Atlas, showing the position of parts in transverse sections of limbs. There are also other outline drawings, giving the position of incisions for various operations. A diagram of the transverse section of the lower parts of the rectum and anus, showing the position of the sphincters and of the openings in various forms of anal fistula, is not a very happy one. The "common form of complete fistula" is represented as coursing beneath the external sphincter muscle. We know that this has been somewhat commonly taught, but in our experience it has been anything but "common" to find that the sphincter muscle is divided in laying open an anal fistula. The common anal fistula is in the subcutaneous and submucous tissue.

The alterations that have been made in the second edition of Dr. Stimson's book are slight. For the most part the former descriptions of operations are unaltered, and we still read on page 346 that in placing a patient for left lumbar colotomy a hard cushion is to be placed "under the *left* side of the abdomen to raise and support it." The recent results of gastrostomy are not mentioned, and it is spoken of as a "very fatal operation." Amputation of the penis is described without mention of such important improvements as bringing the urethra out in the perineum or removal of the entire organ. Again, in the section on amputation at the hip-joint, the arrest of hæmorrhage by the use of Davy's rectal lever is not noticed. Some new operations, such as excision of the kidney, nephrorraphy, and removal of the uterine appendages are described; but we find no mention of nephro-lithotomy. Indeed, the book bears evident marks of too little care in preparation and revision.

Reconstruction of Central London. (Westgarth Prize Essays.)

IT is now more than two years since Mr. William Westgarth offered a sum of £1200 to be awarded in prizes for essays on the subject of the reconstruction of Central London. The proposal to benefit the vast community of four millions of persons by the removal of conditions which prejudice their being, and which have been handed down to them by past generations, is one which reflects honour upon its originator, but the result has on the whole proved disappointing. The enormous magnitude of the work has been too great for accomplishment even by the few who are able to think in a comprehensive manner of the details of a scheme for carrying into effect the intentions of the donor, but Mr. Westgarth's efforts have not been altogether wasted. One of the writers of the essays has pointed out that success could only result when London was sufficiently educated to approve the changes which are known to be necessary; and Mr. Westgarth may certainly be said to have accomplished one of his objects — that of making London think of the need for some larger method of dealing with the faults of construction of the older parts of the metropolis than is now provided by existing legislation or than can be accomplished by any existing authority. London is doubtless improving, but its improvement is carried out in so irregular and patchwork a manner that there is an absence of any uniformity in the steps which are taken for this purpose. To some extent the Metropolitan Board of Works has attempted to overcome this difficulty; but, nevertheless, so-called improvements are being effected and substantial buildings are being erected in localities which should be absolutely cleared of buildings altogether, if the making of roads and streets throughout the metropolis in relation to means of access from one part to another were more constantly kept in view. A work of such magnitude could, indeed, be only successfully undertaken by one mind having a fixed purpose. Such was the case in Paris, where one man, Haussmann, supported by the imperial rule of Napoleon, created the magnificent city of which every Frenchman is proud. But Haussmann left Paris involved in debt, although his intentions were far behind those of Mr. Westgarth, whose thought for London was not limited to the construction of a convenient and beautiful city, but of one which should essentially provide accommodation of a suitable character for the poorest as well as the richest of its inhabitants. He had hoped to have done all this, and yet to have so arranged his plans that the improved value of land and property that would result from these changes would compensate for the outlay. His aim was the establishment of a London reconstruction trust, which, by dealing in a more wholesale manner than is at present possible with London improvements, would prevent much of the expenditure which is now caused by the carrying out of a number of isolated schemes. The essays which are now published deal with different parts of this great subject. The sanitation and reconstruction of Central London is discussed by Mr. William Woodward; while Mr. Henry Hewitt Bridgman has written on street-realignment and reconstruction of Central London; the re-housing of the poorer classes of Central London is treated by Mr. J. Corbet's; and certainly each may claim to have added his share to the information which is required for the undertaking of the task. The committee of adjudication of Mr. Westgarth's prizes have reported to the effect that in their opinion none of the essays realise the requirements of the offer in such a manner as to justify them in recommending that the full amount of prizes should be awarded. The duty, however, has been no easy one, and it is pleasant to think that some contribution of a practical nature has been made to the knowledge which is necessary. Space will not enable us to discuss the essays in detail, but their perusal will amply repay those readers who are interested in the welfare of the metropolis, and they will probably pave the way for a more thorough understanding of the difficulties which have to be overcome.



HOSPITAL FOR DISEASES OF THE THROAT.—The annual general meeting of the governors of this institution was held on the 17th inst., the President, Lord Caltherpe, in the chair. The report stated that during the past year the attendances of patients had amounted to 26,669, or 3000 more than in 1884, with an expenditure for the twelve months of £2838 only. The committee regretted to have to point out that donations and subscriptions showed a falling off, and they strongly urged upon the charitable the necessity for additional funds.

New Inventions.

NEW NASAL SPECULUM.—NEW TONGUE-DEPRESSOR.

THE instruments figured below have been introduced by Staff Surgeon T. D. Gimlette, R.N., and are manufactured by Messrs. Arnold and Sons, West Smithfield. The first consists of two pairs of fenestrated blades of white metal joined in the middle by a hinge, so that when one pair of blades is open the other pair is closed. The following advantages are claimed for it over the ordinary nasal speculum at present in use. The fenestrated blades enable the surgeon

to inspect the mucous membrane of both ala and septum nasi at the same time, the whole nasal cavity on one side being exposed at once. It is more easily introduced, and causes less pain than the ordinary speculum, the curves of the blades being those of the ala and septum respectively. It lies flat against the face when introduced, and is very little in the way of any operative procedure. The advantage of having the instrument double is obvious. It is simple of construction, and its cost is moderate.

The other instrument is submitted as being more handy and portable than the ordinary tongue-depressor or spoon-handle. The curve of the instrument, the fenestrations of

the blade, and its shape fitting that of the root of the tongue, render the control of that organ by the observer more perfect and the examination of the fauces more easy. The small end is for use with children.

PAULSON'S PATENT PERPETUAL FILTER.

A STONEWARE filter of somewhat peculiar construction. The outer jar contains a second, which slips into it, leaving an open space at the bottom. The inner jar, which is perforated at the top and bottom with small holes, contains the metallic filtering agent, and into this the water is poured. The cover is hollow, and a mixture of carbonate of soda and tartaric acid introduced into it with a little water causes an evolution of carbonic acid, which is supposed to aerate the water. We followed these directions closely, but did not observe any alteration in the taste of the filtered water. One great advantage of the filter is the ease with which it can be made to renew its activity. For this purpose it is only necessary to lift out the inner jar and heat it for several hours in an oven. This filter has been designed by Mr. W. Paulson, L.R.C.P.L, of Loughborough.

PATENT AMBULANCE WAGGON.

MESSRS. LEE AND TAYLOR of Leicester have brought out a new hand ambulance waggon and stretcher, in which they claim to have combined lightness with great strength and smoothness of running. Underneath it is an "emergency box," containing a few simple medicines, with some splints and bandages. It has been favourably reported upon by several medical officers who have had an opportunity of testing it practically, and it seems well adapted for use in connexion with the police and town hospitals in cases of accident. It appears to us, however, to have a serious drawback in being constructed with four wheels, as it obviously cannot be turned in so limited a space as one which runs upon two wheels.

HYDROPHOBIA.

To the Editor of THE LANCET.

SIR,—I should like, with your permission, to offer a few remarks regarding Surgeon-Major Pringle's paper on the above subject, which appeared in your issue of April 24th, 1886. Is it not possible that the author attaches too much importance to the suction of the wound, and too little to the incisions which were made? It seems to me that free hæmorrhage is a very considerable safety-valve in the case of a bite by a rabid animal; so much so, indeed, that I believe it is good practice, in wounds that are punctures, to incise them, with a view to the encouragement of bleeding, which expels some of the virus, and to facilitate the application of a caustic. I believe it would be a most dangerous precept to condemn cauterisation in the bites of rabid animals. The procedure I have for some time advocated is the following: The wounds should be most thoroughly washed out—deep wounds by means of a syringe—with a warm weak solution of permanganate of potash; punctured wounds being first incised, and bleeding encouraged. After this has been done, each wound should be carefully wiped, and powdered permanganate of potash rubbed into it. When the wounds are deep, injections of a 5 per cent. solution of permanganate should be had recourse to. Now, what are the objects of this treatment? They are (*a*) to cause the expulsion of as much of the virus as possible; (*b*) to neutralise any virus that may remain; and (*c*) to cauterise the part so as to convert it into dead tissue, which, as we know, is incapable of performing the process of absorption. I advocate the use of the permanganate of potash, because I know from practical experience that it has the effect of rendering snake poison, —which appears to be allied to rabic slaver—quite inert. Under any circumstances, I hold that incision, and, in cases where the wounds are ragged, excision, the neutralisation of the virus, and the cauterisation of the parts are the measures which are best calculated to prevent the absorption of the virus into the general system.

I do not propose here entering into a discussion of the merits of M. Pasteur's method; but I cannot help saying that there appears to exist an unreasoning acceptance of assertions in its favour to the exclusion of facts which are unfavourable. So far as I can gather, the very essentials of proof on scientific grounds are wanting. There is nothing whatever to show that the numerous persons being inoculated at his laboratory were bitten by rabid animals, if we except the fatal cases; nor is there anything to show how far immunity from rabies may have been due to causes other than those claimed by M. Pasteur. Nor has sufficient time elapsed in any given case to warrant the assumption that the period of incubation has yet passed.

I remain, Sir, yours truly,

Goalundo, May 15th, 1886. VINCENT RICHARDS.

COLONIAL AND INDIAN EXHIBITION.—Arrangements have been made for the examination in the Indian Court of certain commercial products, which are believed to be insufficiently known or to be suitable for new purposes. Among the substances which will be examined are fibres, silk, and silk substitutes, drugs, tobacco, gums and resins, minerals, oils, oil-seeds and perfumery, dyes, mordants and pigments, timbers, tanning materials and leather, and food-stuffs. Any visitors to the Exhibition, who are interested in the subject, will be permitted to attend these examinations of products, which will take place in the Commercial Room, attached to the Economic Court, where all further information may be obtained.

NATIONAL DENTAL HOSPITAL.—The first dinner in aid of the funds of this hospital will be held on Tuesday, the 29th June, 1886, at "The Albion," Aldersgate-street, Alderman Sir Robert N. Fowler, Bart, M.P., in the chair.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, JUNE 26, 1886.

No arguments against general hospitals, or in favour of a merely stingy and critical support of them, will hold water. Hospitals are institutions for a generous treatment. Their open doors, their high skill and service, the poverty and sickness of the great majority of their inmates, and covering life itself with a cloud, ought to disarm criticism. When to this is added the remembrance of the work done in hospitals considered as schools of medicine, where the surgeon and the physician learn the art with which in after-time they are to save the life of the rich and the comfortable classes, their claim to generous help is indeed overwhelming.

The Christian arguments will be plied to-morrow with more force than ever. It is thought disadvantageous for the advocate of a great cause to have to acknowledge a favourable state of the finances or the existence of a balance at the bankers. On this occasion the ministers of religion will have all the advantages of a huge deficit. Our carefully drawn tables show that on last year's working alone the hospitals and dispensaries of the metropolis have a deficit of £40,335, and in some of the largest and best institutions of London the deficiency is painful. Take, for example, the London Hospital, contending with the hospital needs of the East-end. Its deficiency alone on common work is £8211, without including an extra expenditure on building of over £9000. King's College for the year has a deficit of £4000; University College of between £3000 and £4000; this without reference to the accumulating deficits of previous years.

HUME, in his account of Queen ELIZABETH, has a fine speculation on the decline of ancient hospitality among the nobility, and attributes it largely to habits of luxury, which dissipated the immense fortunes of the ancient barons. In the time to which we refer hospitality, in the ordinary sense, existed still on a princely scale. There were actually no hospitals, excepting St. Thomas's and St. Bartholomew's, in the kingdom. The provinces were without an institution where a poor man with a broken leg or a fever could be accommodated with a bed. Since then hospitals have become a feature of our civilisation. Every important town in the country has its hospital or infirmary, where the poor man, or his wife or child, in grave conditions of accident or disease, may have a physician and a nurse equal to those who minister to the wealthiest nobleman in the country, or to Royalty itself in the metropolis. This is true hospitality. Is it declining? and if so, what account shall we give of the fact? The hospitality of which HUME spoke is on the increase; it is no longer the exclusive privilege of the baron or the nobleman; it is diffused through society, and in the houses of many of our merchants we may see a more sumptuous dinner or a more gaily apparelled company than was seen in many of the halls of the ancient nobility. We shall be told that times are bad. So they are; but much luxury still survives. A superfluity of hospitality not only in the City companies, but in every rank of life, obtains. A month's—we will not say economy—a month's simplicity of living and entertainment in London would supply the deficit of the hospitals, and add £40,000 to the Hospital Sunday Fund. This is a simple prescription. It would not perceptibly diminish London trade; it would immensely reduce London ailment. Nobody would suffer—save, perhaps, London doctors; and it would redeem our society from the charge of frivolity and luxury, when want, disease, and emaciation cry in vain for admission—for a bed either to be cured on, or to die on, in a London hospital. Shall all hospitality for the rich, the gay, and the strong go on, and the hospitality for the poor, the pinched, and the sick wither? Some of the poverty of our hospitals arises from the fact that the new classes of society, to which wealth has been largely transferred, have not realised the case and the claims of hospitals. The middle class is blamed for using the hospitals and dispensaries, for sending their servants to them, and sometimes even going themselves, but forgetting to send their guineas to the treasurer. This is certainly largely true. But

> "Evil is wrought by want of thought,
> As well as want of heart."

And here, we really believe, it is largely want of thought. Men do not "think," do not "consider" the case of the poor man—short of money, short of breath, with little accommodation in his home when all goes well, and none when disabled by accident or illness. But the excuse of "want of thought" cannot much longer be made. Hospitals are being starved out of all proportion to the badness of the times, while millions are being squandered on luxury. The starvation of hospitals is published in every newspaper and from every pulpit. Patients in hospitals are not fed by manna from heaven; they depend on "good Samaritans" passing by, on their fellow-workmen, on merchants, and on men who are the proprietors of "heaps of gold." Our theory is that out of every such "heap" a hospital should be constructed, which should be maintained by the trained self-denial of people in the possession of ordinary health and means. Sir ANDREW CLARK has well told us that the entertainment of the poor in hospitals is not only a matter of divine charity, but of human prudence. Let to-morrow's collection show that we have taken his wise and warning words to heart.

A SHORT time since a paper was read at the Sanitary Convention of Ypsilanti, Michigan, by Dr. ERWIN F. SMITH, which sets forth in an exhaustive manner the influence of efficient sanitary measures in controlling and reducing mortality. Incidentally, our comments on the reports of medical officers of health are constantly pointing out how great this influence is, and how dependent national prosperity is on the saving of human life from the more preventable diseases. It may be a question whether financial gain accrues to a community by the adoption of measures which go to prolong an old age which is comparatively useless for State purposes, but no such question can arise as regards the control of many of the more preventable diseases, such as enteric fever and phthisis, which kill the breadwinners, leaving whole families dependent for

Digitized by Google

support on public funds, and which, as regards the latter disease at least, go to enfeeble subsequent generations. We do not propose to follow Dr. ERWIN SMITH into the many details which he brings forward to show that well-designed works of sewerage and of water-supply have caused a reduction in the death-rates of the cities affected; but it is useful from time to time to give prominence to the general conclusions which are involved in records such as he has set out for the guidance of his fellow-workers.

Nature exacts the utmost penalty for breaches of the laws of health, and no amount of ignorance is ever accepted by her as a reason why infraction of those laws should not be followed by their natural consequences. In olden days, when a halo of superstition obscured all recognition of the laws relating to epidemic disease, nations were swept over and over again by disorders such as plague, sweating sickness, and the like, hundreds of thousands of human beings perishing miserably from affections which are now either altogether things of the past, or so limited in their area that this very limitation serves to indicate the causes of their prevalence by mere contrast of the sanitary circumstances which prevail within, and are absent and without, the affected zones. And so it still remains. Thus, notwithstanding the rites and processions carried out in Naples in 1884, the city remained as much scourged by cholera as if nothing had been done, and it was only when an attempt was made to cleanse the town of some of its more glaring sanitary defects, and when later on a pure and abundant supply of water was brought in to replace the polluted services, that some initial advance was made in the direction of preventing the disease. So also Paris, with its 80,000 cesspits and numerous shallow wells, is repeatedly the subject of typhoid fever epidemics; and Toulon, which is aptly described as "a plague spot from time immemorial," has hardly ever escaped from any epidemic coming within its range. At times some event, such as the great fire of London, which at first appears to be an unmingled national calamity, forcibly points out what are the conditions that need removal in the interests of health, and it may be hoped that the special localisations of cholera during the epidemic of the past two years may teach a similar lesson. We got rid of plague in the metropolis by the fire which consumed so much of the city; but the lesson was not fully appreciated, and we again began to aggregate houses on small areas, until, in almost all our large cities, we had constructed permanent typhus centres. Now we are endeavouring to undo this mischief, and it is doubtless in the main due to the vast demolitions of bad house property under the Artisans and Labourers' Dwellings Acts, and in connexion with other works, that London has now for so many years remained free from a typhus epidemic.

With cholera still persistent in certain parts of Europe, and with the knowledge that this same disease has with unerring certainty settled on our insanitary spots in the past, it is most important that we should remember the implacable claims of Nature, and the certainty with which she levies a death tax on those communities and spots that refuse to be taught by past experience. Intervals, and sometimes long ones, are granted in which to do away with the evils which have marked the past; and so far as cholera is concerned, we have in this country been favourably dealt with in this respect. But Toulon, Marseilles, Naples, Palermo, Paris, and many Spanish cities, also had their opportunity, and when the infection came near them, their sanitary administration was weighed and found wanting. There are places in this country of which the same may have to be said, but it will not be for want of warning. Improvement in England has, we believe, been very general in sanitary matters, but the causes of preventable disease will find their way through any weak points in the sanitary armour of our cities and villages that may be left exposed, and to these each sanitary authority and each responsible citizen should turn his attention whilst there is yet time.

ALPINE and athletic clubs are hardly less interested than the physiologist in the elaborate series of experiments recently made by Drs. MOSSO and MAGGIORA on the laws of fatigue, and described by them in the monograph just presented to the Accademia dei Lincei. These accomplished inquirers began their operations by constructing a mechanism by means of which they could observe the variations of the efforts put forth by a finger in lifting a weight until entire exhaustion had set in. The mechanism was then readjusted in such a way that the operator's whole arm remained motionless, with the one exception of the muscle corresponding to the finger in action. The variations of the muscular effort were graphically traced on blackened paper, and from these tracings it resulted that every individual under experiment gave a special characteristic trace, which at once distinguished his effort from those of the others. Resistance to fatigue was then seen to be different at different hours of the day, and the influence of food upon it was also found to vary. Further, a special study was made of the important problem of the disposing of pauses, so as to make the outlay of force as economical and as effective as possible. The practical importance of these inductions to pedestrians or soldiers on the march is obvious. According to Drs. MOSSO and MAGGIORA, the resulting fatigue is twofold—the fatigue of nervous failure and the fatigue of muscular failure. In certain cases the fatigue comes from the collapse of the muscular tissue only, while in others it happens that the brain suspends the supplies necessary to keep the muscles active. Some experiments showed that if a fatigued finger bore a weight with difficulty, the moment the weight was withdrawn the finger recoiled backwards with force—a proof that while the muscular energy had run out, the nervous energy was striving to compensate it by imposing on the muscle an effort much stronger than necessary. Professors MOSSO and MAGGIORA next describe a series of experiments on the influence of the weight to be lifted, as well as on that of anæmia. To ascertain the latter, they constricted the arteries of the arm under experiment by impeding the afflux of blood, or they rendered it totally bloodless by encasing it in strong ligatures of gutta-percha. In this condition the muscle was found capable of continuous effort, but only through nervous excitation, while it was observed in what manner the muscular energy revived gradually as the blood returned into the arm. The effects of fasting, and the duration of time that must elapse after

Digitized by Google

the taking of food to re-establish the conditions of normal muscular labour, formed a further series of investigations, in connexion with which there was determined the influence of respiration and of those processes of training whereby the organism is inured to bear the heaviest fatigue, as in the case of Alpinists before undertaking a formidable ascent. Finally, Drs. MOSSO and MAGGIORA overhaul afresh the familiar experiments as to what and how great is the influence of certain aliments in the production of labour, whether their action is beneficial or not, confirming by novel methods the induction that alcohol, so far from augmenting muscular energy, positively diminishes it, while other ingesta increase the output of work by substantial reinforcement of the organism. The monograph, on its publication, will be found not to disappoint the expectations formed as to its merits from the previous researches of these eminent physiologists of the sub-Alpine school.

AT the time of our writing the Medical Bill has yet to become a Medical Act. At the last moment, and in the "hurry-skurry" of a premature dissolution, Parliament has been exercising its little power of altering the balance of parties (so to speak) in the Medical Council. Our readers will remember that the only serious attempt of Parliament in the House of Commons to modify this imperfect measure was in the matter of representation on the Medical Council. The friends of the Victoria University made a determined stand about two o'clock in the morning, when most of the members either were or should have been asleep, to get a representative on the Medical Council to themselves; and they succeeded. Then followed the similar attempt of the friends of Aberdeen and St. Andrews; but they failed. The House of Lords has been more propitious. Under the effective lead of the Chancellor of the Aberdeen University, the Duke of RICHMOND and GORDON, the Lords have granted what the Commons denied—a separate representative to Aberdeen and St. Andrews respectively. It is not easy to see how this plea is to be resisted after the privilege of separate representation has been conceded to Victoria University. But, for all that, it is inconvenient. As the Bill left the Commons, England had 14 representatives—i.e., direct representatives 3, Crown 3, University 5, Corporations 3; Scotland, 8—i.e., direct representatives 1, Crown 1, University 3, Corporations 3; Ireland, 7—i.e., direct representatives 1, Crown 1, University 2, Corporations 3. Nobody will say that England has more than her share here. But the numerical disproportion of representation between Scotland and Ireland was a matter of some delicacy, Scotland having one more member than Ireland. The Duke of ARGYLL said in the House of Lords that he had no objection to Ireland having a dozen members if she had as many universities. But the question is by no means so easy of solution as the Duke would imply by this off-handed speech. The whole system of representation of individual institutions is bad. It necessitates a large and costly Council, and every representative is tempted to look at every question of medical education or examination through the spectacles of his particular "body." This evil is notorious; it has tended and will tend to keep down the public respect for the Council. The Royal Commission recommended a smaller and differently constituted Council, as we have always done—one in which the bodies were collectively represented, not singly. No such improvement, however, has been made, and the time has gone for making the attempt. Before this reaches the majority of our readers the Bill will be either lost or passed. In the latter event it will be our duty next week to consider it in more detail.

Annotations.

"Ne quid nimis."

THE ACCESSION OF QUEEN VICTORIA.

THIS being the opening of the fiftieth year of Her Majesty's most happy reign, all classes of the Queen's subjects are eager to celebrate the jubilee with all the enthusiasm with which loyalty to the Throne and respect for the personal merits of the Sovereign inspire the nation. Already the opening notes of the thanksgiving festival have been sounded, and appropriately enough in the Hall-Chapel of the Temple, where the premier society of law interpreters held high carnival after the manner of olden times, and afterwards went to church on Saturday, the eve of the Accession Day. There will be ampler opportunity and more fitting occasion to revert to this subject later on; but we cannot let the week pass without placing on record the expression of a sentiment which pervades the population, and has no firmer hold anywhere than in the minds and hearts of the members of the profession of healing and health-preservation—a sentiment of respectful and earnest well-wishing for the health, happiness, and continued prosperity of the Queen of England, Victoria, whom God save.

THE COMING ELECTION AT THE COLLEGE OF SURGEONS.

BEFORE our next number appears the College election will be over. We must once again impress on Fellows the importance of the occasion and the great desirability of voting for men whose influence will be given in favour of that reform which is as widely demanded by the constituency as it is necessary to the advancement of the best interests of the College. We would especially hope that provincial Fellows will make an effort to be present, in order not only to secure an ample representation of their own body, but also to help in the election of the most enlightened of the remaining candidates. We reproduce the list of candidates published in our issue of the 12th inst. They are as follows:—Mr. Lund and Mr. B. Hill, who seek re-election; Messrs. Sibley, Couper, Willett, Rouse, Brudenell Carter, and Reginald Harrison. Among the metropolitan candidates, Mr. Sibley, Mr. Willett, and Mr. Couper are perhaps the most conspicuous. We could have wished that Mr. Holmes had allowed himself to be nominated; his outspoken views, his high professional standing, and his past experience on the Council would have secured for him a full vote. Among provincial Fellows, Mr. Lund and Mr. Harrison are so well known, and their respective claims on the constituency so well acknowledged, that they need no present commendation at our hands. This present election should be a memorable one, and should be the means of convincing the Council of the earnestness of the Fellows at large in the cause of reforms which, though advocated for many years past, have been persistently refused or ignored by the Council. We may hope, ere another election comes round, that personal voting will have been abolished, and that Members of the College will have been granted their legitimate corporate right of voting and of being directly represented on the Council.

UNIVERSITY OF LONDON.

A MEETING of Convocation will take place on Tuesday, the 29th inst., for the purpose of nominating "a list of three persons to be submitted to Her Majesty for the selection therefrom of a Fellow of the University." Mr. William Thistleton Dyer, B.Sc., Mr. Philip Magnus, B.A., B.Sc., and Dr. Samuel Wilks, M.D., have been proposed. Mr. Dyer's nomination-paper is signed by 275 graduates, Mr. Magnus's by 450, and Dr. Wilks's by 659; so that if the voting-papers show a like return there will be no question as to the selection of the last-named physician. There is a large amount of business on the agenda paper, besides the further consideration of the report of the special committee upon the constitution of the University adjourned from the special meeting of May 25th. Mr. Newsom, LL.B., is to nominate a special committee of seven members to consider the regulations for the examinations for the degrees in laws. Mr. Tyler and Mr. Lynn are to move resolutions affecting the constitution of the University, which will, we imagine, hardly be entertained if the report of the special committee be adopted. Mr. Whitehead and Mr. Nesbitt revive the question of establishing a doctorate of literature or philosophy, in accordance with a resolution passed on Feb. 3rd, 1885. Mr. Cotton proposes that the University should appoint professors and tutors "to promote the progress of graduates to higher degrees." Mr. Whitehead has resolutions having reference to the proposed forthcoming Jubilee celebration. Mr. Round wishes to change the hour of meeting of Convocation, and will move to refer the question to the annual committee. Mr. Spratling gives notice that he will move a resolution in favour of the Senate being enabled to appoint joint committees of the Senate and Convocation or other recognised bodies within the University; he also intends to move that it is unconstitutional and inexpedient to suspend any standing order without due notice.

POISONING BY WOOD-SORREL.

ON June 15th an inquest was held at Gravelly Hill, touching the death of Edward Arthur Geary, aged five years. From the evidence, it appears that deceased ate a "large quantity" of green sorrel (sorrel dock, Rumex acetosa); that next morning, feeling dazed and thirsty, he drank some soap-and-water which stood at hand; and that shortly afterwards he became unconscious and died at five in the evening of the same day. Now, the active poisonous agent in sorrel is oxalic acid, but from personal knowledge and experience we can say that a very considerable quantity of the leaves may be ingested without producing unpleasant, much less dangerous, symptoms. The theory of the medical men engaged in the above case was that the alkali of the soap combined with the acid of the leaves and formed soluble salts of sorrel, which caused the fatal toxic symptoms. We are inclined to think that such combination may have occurred, but whether potassic or sodic oxalate was produced in quantity large enough to cause lethal effects we are somewhat sceptical. It may have been that the poisonous action, owing to slow absorption of oxalic acid from the partially digested leaves, had commenced, and that the symptoms were intensified by the alkaline oxalate. It is a question of toxicological significance, and one well worth working out in the laboratory. It is an instruction in cases of oxalic acid poisoning not to give alkalies on account of the highly poisonous action of the salts generated. Lime forms an insoluble oxalate, and is thus indicated. Theoretically the case seems on paper to be complete, but we should require to be assured that other and, as it seems to us, more probable causes of death had been eliminated before we accepted the verdict of the jury, although it was in accordance with the medical evidence. Neither Taylor nor Guy makes mention of poisoning by sorrel leaves, either alone or in combination with alkali. We should like to know whether the fluid the child drank was simply *soap-and-water*, or a solution of soap less, which might contain a fatally poisonous dose of carbonate of potash. Subject to correction, we are disposed to believe that the death was owing to the "soap-and-water," and that the sorrel leaves had but little to do with the unfortunate event.

THE NECROPSY OF THE LATE KING OF BAVARIA.

THE supplement to the *Allgemeine Zeitung* of Munich of June 16th contains the following account of the *sectio cadaveris* of the late King Louis II. of Bavaria. The necropsy began at 8 A.M. of June 15th, and ended at 1 P.M. It was performed by Professor Rüdinger, with the assistance of "privat docent" Dr. Rückert, the "protocol" being drawn up by Geheimerath von Ziemssen, in conjunction with the above-named professors, and the three alienists, Hofrath Hagen, Professor Grashey, and Director Hubrich. Among those who were present were Professor Kupffer and the body-surgeon of the late King, Dr. Schleiss von Löwenfeld The embalmment, which took place immediately after the necropsy, was performed by Professor Rüdinger and Dr. Rückert, and succeeded extraordinarily well, being finished at 8 P.M. The body had a length of 191 centimetres, the circumference of the chest being 103 centimetres. There was a pretty thick layer of subcutaneous fat, while the osseous and muscular structures were particularly strongly developed. The corpse was somewhat swollen in the face and neck, the skin of the head, especially about the ears being of a livid tint, while on the surface of the trunk and limbs there was diffuse cadaveric petechiæ. As for wounds, with the exception of some small cuticular excoriations on the knees, none were discoverable. The tongue was slightly clenched between the teeth, while the latter were in many places defective [carious?]. The skin of the scalp was very thick and enormously vascular. The skull, in proportion to the size of the body, was small and somewhat asymmetrical, the diagonal diameter from the forehead to the occiput, from left to right, being 17·2 centimetres, while that from right to left was 17·9 centimetres; and the wall of the skull was extraordinarily thin, the greatest thickness being 3 millimetres. The coronal and sagittal sutures were completely ossified on the inner aspect of the cranium, while a row of greater or smaller osseous growths existed on either side on the inner surface of the frontal bone. The superior longitudinal sinus was much dilated posteriorly, while, on the other hand, it contracted anteriorly towards the ethmoid bone in a remarkable degree; and Pacchionian bodies projected in groups into the channel of the sinus. The dura mater was in general considerably thickened, especially over the frontal lobe of the brain; it was vascular, rough, and villous on the outer surface. On the clinoid processes was an osseous outgrowth, projecting to the extent of 2 millimetres. On the left petrous bone was a prominence of 1 centimetre in basal diameter, corresponding to a depression on the temporal lobe of the cerebrum. The dorsum sellæ was asymmetrical, thickened to an important degree, porous, and brittle, as was also the floor of the anterior fossa of the skull. All the sinuses at the base of the skull were distended with dark fluid blood. The weight of the brain, without the dura mater, was 1349 grammes. The arachnoid membrane was thickened to a great extent on both hemispheres, and with milk-white opacities. At one spot—namely, over the mesial extremity of the left anterior central convolution [ascending frontal] and the commencement of the first frontal gyrus—the arachnoid and pia mater were adherent for the area of a mark-piece, and thickened to a tough callosity, while from the pressure

Digitized by Google

of this latter the corresponding part of the cranial vault was reduced to a paper-like thinness. On the surface of the brain, pretty evenly distributed on either side, there were shrunken regions of the convolutions—namely, on the commencing portions of all three frontal gyri, on the mesial extremity of the anterior central convolution, and in the neighbourhood of the middle section of the post-central sulcus. The cerebral substance was vascular and somewhat soft. As regards the other organs of the body, the following was noted: The lungs, with the exception of the effects of the aspiration of water, were in a completely normal condition. There was no trace of pleural adhesion. The heart was somewhat larger than normal, but of strong muscular structure, and with but a moderate covering of fat. The stomach, which still retained some remains of undigested food, was in a state of chronic catarrh. The walls of the intestines and the liver were congested, and the spleen enlarged, being in a state of commencing decomposition. The kidneys were large and extremely cyanotic, but otherwise normal.

HUNTER'S HOME.

NOT long since we had occasion to draw attention to the impending destruction of John Hunter's House at Earl's-court. Now the work has been completed, and the place is being laid out as a square. A correspondent of a contemporary calls attention to the fact that the builders have obtained permission to name the new thoroughfare "Barkstone-gardens," and suggests that it should receive instead some appellation that would perpetuate the memory of Hunter. We heartily subscribe to this suggestion. The name fixed upon at present may not be inappropriate in itself, but the occasion surely warrants that the greatest person and circumstance connected with old Earl's-court House should be fixed upon to give the new nomenclature. It may not seem a matter of signal merit that here it was that John Hunter kept his caged lions and prepared the skeleton of O'Brien. When, however, we contemplate the prodigious labours of the great anatomist, we cannot help feeling that anything, however small, done in laying the foundation of the magnificent collection at Lincoln's-inn-fields is worth recording; and surely the most fitting place is the scene where Hunter devoted a part of his life's work. We have placed "Cleopatra's Needle" on the Thames Embankment to commemorate, as we suppose, the "dalliance and the wit" of the swarthy Egyptian Queen. Thousands of pounds were spent to bring and rear in our midst an obelisk of uncertain history. Why, then, should we from simple negligence fail to honour, if only by a name, one who has done a thousand times more to make the world healthful and happy than she who "rode on Fortune's neck" and "governed men by change."

SCARLET FEVER IN THE FERNDALE VALLEY.

THE epidemic of so-called "black fever" which was announced to be prevalent in the Rhondda Local Board of Health District turns out to be scarlet fever. But the epidemic is evidently on a wide scale, 350 cases and 24 deaths having occurred up to the 17th inst. According to a correspondent much reliance is being placed on disinfectants as a means of prevention, but although we would by no means undervalue the effect of really efficient means of disinfection by which such materials as bedding and clothing can be rapidly and thoroughly penetrated by a high temperature, it is obvious that in isolation the true remedy against scarlet fever must be found. When once the disease has gained the dimensions of an epidemic it is clear that the time has passed in which all cases can be isolated by the sanitary authority, and hence it is that it is so important to have in readiness beforehand means which will suffice for the isolation of the first cases, and which shall be of such a character as to attract the sick. The provision of hospital accommodation during an epidemic, and with a view of meeting it, is, as a rule, a mistake; but the occasion may well be used to inaugurate an efficient scheme by which the next appearance of the disease may be met in such a way as to prevent another epidemic.

HOSPITAL SUNDAY FUND AND THE THEATRES.

ALTHOUGH the managers of the London theatres have not apparently seen their way to give effect to our suggestion of a special "Hospital *Matinée*," it is pleasant to record the aid they are giving this week to the Hospital Sunday Fund. During the present "Hospitals week" collecting-boxes have been placed at the various entrances for the public as well as at the stage doors and in the "green-rooms" of the following theatres: Adelphi, Britannia, Criterion, Court, Gaiety, Globe, Grand, Haymarket, Her Majesty's, Lyceum, Pavilion, Prince's, Princess's, Prince of Wales (Greenwich), Opera Comique, Strand, Standard, Surrey, Sadler's Wells, Savoy, Toole's, and Vaudeville. It is announced that there will be no detailed statement as to the amount collected at each theatre, but that the money collected at all the various houses will be handed over to the Lord Mayor in the aggregate as their joint contribution. The theatrical profession is notoriously a generous one, and it is to be hoped that playgoers generally will appreciate the fact that a small addition to their expense this week for amusement and recreation, while not felt by them, will assist in doing incalculable good. A correspondent has written to the *Echo* to suggest the extension of the aid of secular places for the Hospital Sunday Fund. Urging the adoption of such a system as prevails in Paris, before the close of the Salon, he writes—"Surely, with us the governing bodies of the Royal Academy, Grosvenor, Royal Institute, and all other galleries could hardly refuse a day or more to appointed lady collectors outside their several turnstiles—days of promising harvest to a great and public need."

INTRA-OCULAR MUSCLES OF MAMMALS.

MANY problems of a difficult nature present themselves in the study of the physiology, histology, and anatomy of the intra-ocular muscles. To some of these Mr. W. H. Jessop has directed his attention, as a paper read before the last meeting of the session of the Royal Society shows. The relationship that evidently obtains between the different groups of muscles themselves as well as to other motor functions specially interests the physiologist; and in this field the aid that disease affords is certainly of considerable value; experimental investigation also promises to throw light on the subject. Mr. Jessop has brought forward arguments to show that the fifth nerve is concerned in some of the functions of the pupillary and ciliary muscles. The pupil contracts to its utmost under direct stimulation of its muscular tissue by eserine, whilst atropine is capable of producing the greatest amount of dilatation of this structure. It appears that the action of the antagonistic agents is the same on the ciliary muscle. The intra-ocular muscles are believed to have similar anatomical, histological, and physiological actions, which their associated action in the act of accommodation would tend to support. The pupil not only contracts when the ciliary muscle does so, but also dilates when the latter relaxes; the latter act, Mr. Jessop states, is carried out through the intermediation of the long ciliary nerves from the nasal branch of the fifth. The ordinary light-reflex of the pupil takes place through the agency of the third nerve; and the cervical sympathetic, as the inhibitory nerve, causes dilatation of the pupil. In mammals

Digitized by Google

the two chief motor functions of the pupil are thus separated; whereas in birds, possessing voluntary control over the irides, this is not so, for the cervical sympathetic has no power over the pupil, the nerve causing dilatation being the fifth. Mr. Jessop draws a clear distinction between the modes of action of cocaine, eserine, and atropine on the neuro-muscular intra-ocular apparatus; the first of these agents acts on the terminations of the cervical sympathetic in the pupil, and probably of those of the fifth in the ciliary muscle; whilst, as above mentioned, the action of the other two drugs is on the muscular tissue directly. Hence it is that, even after section of all the nerves going to the intra-ocular muscles, atropine and eserine can cause further dilatation or relaxation and contraction respectively.

DR. OLIVER WENDELL HOLMES AT CAMBRIDGE UNIVERSITY.

ON the 17th inst., in the presence of a large and enthusiastic assembly in the Senate House at Cambridge, the honorary degree of Doctor of Letters was conferred upon Dr. Oliver Wendell Holmes. The public orator in presenting Dr. Holmes to the Vice-Chancellor, characterised him as one who combined enthusiasm for science with distinction in literature, one who "Phœbo ante alios dilectus" had received more than one gift of Apollo, the gift of skill in the healing art as well as the gifts of eloquence and soul. In allusion to the death of Addison, of which that day was the anniversary, the orator said that the language of eulogy once applied to that writer might appropriately be transferred to Dr. Holmes:—Haud ignobili poetæ, in oratione soluta contexenda summo artifici, censori morum gravi sane sed et perjucundo, levioribus in argumentis subridenti suaviter, res etiam serias lepore quodam suo contingenti." Addison, however, had died in the forty-seventh year of his age, whereas Dr. Holmes was nearly fifty when his fame as a writer burst out into a fresh brightness like that of the Indian summer—"ubi in ipso autumno novus refulget æstatis splendor." The orator concluded in these words:—"Videor mihi vatem quendam canentem audivisse, illum cujus in corde æstas æterna floreret, non vocandum esse senem. Equidem juventutis perpetuæ fontem illum quem trans æquor Atlanticum Hispanorum nautæ frustra quærebant, nautam hunc feliciorem, non fabulosas inter insulas sed Academicæ juventutis in amore perpetuo, in amore mutuo, invenisse crediderim. Trans occidentis amplum illum sinum, levi phaselo vectus, diu naviget; nautili illius ritu, quem versibus tam pulchris descripsit, indies 'per ampliora ad altiora' tendat. Suam Academiam, per tot sæcula feliciter conservatam, intra paucos menses carmine sæculari iterum celebret, diuque superstes ipse exornet; nostræ denique Academiæ honoris causâ adscriptus, diu et nostrum et totius litterarum reipublicæ ad fructum floreat, vigeat, valeat, litterarum doctor, Oliver Wendell Holmes."

SPECIALTIES IN PARISIAN HOSPITALS.

Le Progrès Médical (5th inst.) complains that, in consequence of inadequate recognition by the Faculty of Medicine, the practice and teaching of pediatrics, dermatology, laryngology, otology, and other special departments of medicine and surgery are very imperfectly provided for in the French capital—so much so, indeed, that French students who desire to perfect themselves in special subjects are compelled, at great expense and inconvenience, to cross the Rhine and study in Vienna or Berlin. The admission of German superiority is a proof of candour which, coming from a leading French journal, possesses the charm of novelty and bears the stamp of truth, which it is very creditable, but cannot be pleasant, to avow.

THE NIGHTINGALE FUND.

THE report of the fund of the Nightingale Home or School for Nurses at St. Thomas's Hospital, for the year 1885, has been recently published. From the opening of the school in June, 1860, to the end of 1885, a total of 833 candidates have been admitted, and 494 have left the school, after completing a year's training, as certified nurses. There were forty-five probationers admitted during the year, making, with thirty-two who remained from 1884, seventy-seven who received instruction. Twenty-seven probationer nurses were entered on the register as certified nurses after completing their year of training, and of these eleven were lady probationers and sixteen nurse probationers. Nineteen resigned or were discharged as unsuitable for the work, this number of failures being somewhat above the average; want of physical strength is said to be the principal cause of this failure. In the early part of the year an outbreak of an epidemic character occurred among the inmates of the home, traceable to some defects in the structural condition of the building; steps were taken by the governors to remedy this evil, which were successful, and no serious results ensued. Three nurses who had been trained in the school went out to Egypt, where they did valuable work. From the further experience there gained, the opinion is expressed that it is only in fixed hospitals (or hospital ships) used for severe cases, and under a superintendent of nurses, that trained female nurses can be advantageously employed. A note is also made as to the satisfactory progress of the training school at St. Marylebone New Infirmary, where there were twelve nurses undergoing training. From the fact that amongst the expenditure of the year £140 14*s.* is put down as a contribution to the expenses of this training school, it would appear to have a very close connexion with the St. Thomas's school, if it is not a direct offshoot. The fund shows a balance in hand amounting to £1829 19*s.*, after the payment of all expenses, including that of "training hospital nurses"—£1430 7*s.*, a large item. This school has done a great deal in the training of nurses who have joined the National Nursing Institution; the good work of these is well known and highly appreciated amongst the sick poor of many of the worst districts of London. We should like to see a home established in connexion with this hospital where trained nurses could be obtained for work amongst the upper and middle classes, similar to those formed in connexion with the nursing schools of St. Bartholomew's, Guy's, the London, and other hospitals.

OVARIOTOMY IN RUSSIA.

DR. MATVEEFF has published a large amount of information on the subject of ovariotomy in Russia. The first operation in the country was performed by Vantsetti in Kharkoff in 1848, but was attended with a fatal result, Professor Krassovich being the first to perform a successful case in 1862. Altogether the author has collected accounts of the work of ninety-six Russian surgeons. The total number of operations was 696, of which 213 ended fatally: this includes 98 double cases with 32 deaths, 16 pregnant cases with 2 deaths, 50 dermoid cyst cases, only one of which was unsuccessful, and 42 cases of malignant tumour of the ovary, of which 25 were fatal. The ages of the patients varied from fourteen to sixty-eight. Of the pregnant cases, one was as early as the second month and one as late as the ninth; of the 16, 6 miscarried, and 2, as stated above, died. Secondary ovariotomy was performed six times, only one of these cases being unsuccessful. Most of the fatal cases were due to peritonitis; of the total number of deaths (213), this accounted for 133, collapse for 14, exhaustion for 12, and internal hæmorrhage for 10. The general percentage of deaths was about 30. That of different operators who had a record

Digitized by Google

of 25 or more cases varied from 42·9 to 8·8 (Slavianski) and 7·7 (Rein.) According to a letter by Prof. A. Y. Krassovski, which is published in Sir Spencer Wells's work on Ovarian and Uterine Tumours, it is stated that up to 1882 302 cases had been performed by Russian surgeons, with a mortality of 44 per cent. Dr. Matveëff is to be congratulated on his later and more extensive statistics, which show that Russian operators are becoming more and more successful in their ovariotomy results. As to the places in which the operations were performed, nearly all were done in university towns; thus, St. Petersburg claims 294, Moscow 110, Kieff 59, Warsaw 52, Kharkhoff 40, Kazan 28, Dorpat 25, and Helsingfors 4. Of the remaining 84, 46 were performed by Dr. Kuznetski in Nijni-Tagilski in the province of Perm, and 18 by Dr. Ikavitz in Tambova.

THE ANTI-FAT CRAZE.

THERE is inconceivable folly in the fear of fatness. We do not for a moment deny that it is possible the organism may be too heavily packed with adipose tissue, and that the action of its several parts may be hampered by this encumbrance, while as a whole it is needlessly burdened; but this is a totally different matter from the fatness against which the fears of the multitude are, for the most part, unreasonably directed. There is not the least physiological connexion between the accumulation of fat and fatty degeneration. As a matter of fact, what is known as "fatty degeneration" occurs more frequently in those who are lean than in those who are "fat" in a popular sense. It is therefore a misconception to suppose that fatness is in itself a disease. It only becomes morbid when, by mechanical pressure, fat impedes the functions of the organs, or by weight it unduly burdens the body so as to exhaust the strength or make too large a demand on the resources of force and vitality. Unfortunately the true nature of the objections to fatness are not explained, and misconception is rather confirmed than removed by the prevailing mode of urging arguments against "fat" and in favour of remedies by which it is proposed to get rid of it. Practically speaking, it is idle to suppose that fatness can be certainly prevented by dieting. There are many ways of fat-making, and those persons who have a tendency to its production will make fat however they are fed—in truth, almost as rapidly on one class of diet as on another. There are idiosyncrasies which may in a limited number of instances be taken advantage of to check the tendency to form fat, but these specialties of chemico-nutritive function are by no means common; and, speaking generally, it must be said that, except by starving the body as a whole, fatness cannot be prevented. The exceptions to this rule are chiefly such as may be explained on the principle of a special tissue appetite. Thus, for example, a man whose muscular system has been healthily developed somewhat in excess of the other parts of his organism may have what might be called a muscular-tissue appetite of such voracity that it will, so to say, seize upon the bulk of the nutriment supplied to the blood and make muscle regardless of what may be left for the nutrition of nerves, &c. Such a person will lose fat without growing thin, so far as muscle is concerned, by a mere reduction of diet, without reference to the kind of food cut off, so that the latter do not chance to be essential to muscle nutrition. In the same way, though with different results, a "nervous" person, in the popular sense—that is, an individual whose nervous system is in perpetual activity, working incessantly and feeding voraciously,—may consume so much of the food supplied for the body as a whole that only nervous tissue is nourished and the rest of the body languishes. This is an instance of growing thin while feeding well, and it is the converse of the process by which, in another class of persons, growth of muscle persists in spite of a reduced diet. There are, in this way, persons whose specialty it is to make adipose tissue, and they will wax fat even when muscles, nerves, and the higher parts of the organisation are relatively in a condition approaching starvation. These and a score of other matters have to be taken into account when calculating the probabilities—or rather the improbabilities—of success in the endeavour to diminish the fatness of any individual by a system of dieting. As regards the use of drugs against fats, setting aside such obvious modes as robbing the blood of its proper nutriment by purging and nauseating, we do not believe it is practicable to prevent the formation of adipose tissue or even to promote an elimination of fat by the use of medicines, unless it be by correcting some error in the chemico-vital processes of the organic economy, to which a particular remedy may, as a temporary expedient in, here and there, a suitable case, be intelligently directed. Measures against fatness are, from the very necessities of the enterprise and the conditions under which it must be carried out in the great majority of instances, predestined to failure. It would save a deal of disappointment, and a great many incidental injuries to health might be avoided, if these facts could be more generally understood; and we think medical practitioners generally may be fairly asked to state and explain them.

MASSAGE IN SCIATICA.

PROFESSOR MAX SCHÜLLER of Berlin is convinced (*Deutsche Med. Wochensch.*, No. 24) of the superiority of massage over other measures employed in the treatment of sciatica, and relates his experience of fifteen cases—all in males, and, except in one or two instances (which were traumatic), due to exposure to cold. Most of the cases were dealt with from the first by massage; but in a few instances electricity, vapour baths, &c., had been fruitlessly employed prior to coming under his care. The *modus operandi* is as follows. The patient lies on the unaffected side with knees and hips slightly flexed. The course of the sciatic nerve is rubbed from below upwards, partly with both thumbs, partly with the ball of the little finger or thumb; sometimes struck with the closed fist, sometimes the muscular mass over the nerve pressed and kneaded with both hands. The pain evoked by these manipulations soon passes away, and after a short time becomes less and less at each sitting. The neuralgic pains very soon abate, diminishing after a severe and painful massage, then recurring with less severity, and gradually disappearing entirely. The power of walking improves after each sitting. On an average the treatment lasts about two weeks and a half, but in one case nine days, and in several from ten to fourteen days sufficed. One patient abandoned the treatment after five days, owing to the pain caused by it, and tried without relief a fortnight's course of electricity and vapour baths; he then returned to the massage treatment, and was cured in two weeks and a half.

SMALL-POX v. VACCINATION.

DR. FAIRLIE and Dr. M'VAIL have very kindly entered into a newspaper controversy with the anti-vaccinationists in the *Glasgow Herald*. We are disposed to doubt whether such controversies ever convert the real anti-vaccinator; but those who are open to reason cannot fail to be convinced by the extraordinary facts showing the enormously reduced mortality of those vaccinated compared with that of those unvaccinated, and the practically absolute immunity of those who are successfully vaccinated and successfully revaccinated. Dr. Fairlie seems in this controversy to have given some sanction to the practice of making one vesicle, as against three or four. This is to be regretted. It is clear that the protection is in the ratio of the number of scars.

Digitized by Google

The experience through which Zurich is passing might well make the anti-vaccination philosophers pause. In Switzerland, from very doubtful notions of liberty, the Federal Council made compulsory vaccination a cantonal affair instead of a federal one, as it had been before. Most of the cantons were wise, and kept to compulsory vaccination; but in Zurich they were extra-wise, and repealed the compulsory vaccination law. This was in May, 1883. In that year, as in 1882, the deaths were *nil;* in 1884 the deaths rose to eleven; in 1885 to seventy-three; in 1886, for only three months the deaths are eighty-five. *The Times* correspondent says the law will be re-enacted. Of course; the door will be locked again, but the steed has been stolen. We doubt, however, whether anything but small-pox will preserve the equilibrium of some minds on this subject. It is a great teacher. The correspondent, quoting statistics lately published by Professor Durrant, compares the mortality from small-pox in twenty-one German towns in 1885, having an aggregate population of 4,306,933, and under compulsory vaccination, amounting to twenty-seven, with the mortality in fifteen French towns, with a population of 4,200,840, for the same year, amounting to 806, or thirty-two times more than in the larger population.

RADICAL CURE OF VARICOCELE BY EXCISION.

Il Bullettino of the Royal Academy of Medicine of Genoa (No. I., 1886) reports a case in which Professor Ceci successfully treated a large left varicocele by excising the dilated spermatic venous plexus. The patient, aged twenty-two, suffered great inconvenience in consequence of the enlargement. Under chloroform, an incision two and a half inches long was made on the left outer side of the scrotum down to the vein, the distension of which was maintained by an assistant exercising pressure at the external abdominal ring. With a director, the vas deferens and the spermatic artery were carefully isolated from the vein, which was secured with two catgut ligatures at the abdominal ring and near the testicle. The varicose venous plexus was then excised. The skin wound was closed with a catgut suture, a drainage-tube having been placed in the lower angle. On the eighth day, when the dressing was changed, there was some œdema of the scrotum; this part as well as the inner surface of the thigh was the seat of carbolic eczema, and carbolic necrosis had attacked the edges and the bottom of the wound. These symptoms disappeared under borax and iodoform, and the patient made a perfect recovery. Professor Ceci considers that the technical progress in operations for varicocele due to the influence of aseptic and antiseptic precautions, justifies preference for excision of the vein over difficult and complicated methods.

POISONED BY WILD FLOWERS.

ABOUT a fortnight since a little girl, aged seven years, died at Glasgow, as alleged, from having sucked the bloom of some poisonous wild flower. The child had been taken on a Sunday-school excursion into the country. During their ramblings wild flowers were gathered, and posies were arranged and garlands woven, as is the wont with children set free from the care and discipline of schools and allowed to roam fancy free in meadows and by hedgerows. In their delight at nature's fairest gifts, little did the denizens of the big Scotch town dream of the poison that lurks within the spathe of the cuckoo-pint (Arum maculatum), or in the clusters of purple blossoms of the woody nightshade (Solanum dulcamara). In fact, the flower of this plant is so like in form and arrangement to that of its innocent first cousin, the esculent potato, that we can understand how a knowledge of the harmlessness of the culinary tuber may have suggested a riskless indulgence in the flowerets of the former. In these days of School Board exaction, is it too much to ask that our children should be instructed, if only in simple fashion, in the broad principles of botany and zoology, and taught how to recognise the plant that nourishes and the one that kills—the harmless snake and the poisonous adder? It is not necessary to go into technical details and to use harsh scientific words to instil into a child's mind that which may be of good service to it when brought in contact with the floral beauties of spring and early summer, or with the berry clusters of a later season. What could be more interesting to a hard-worked, brain-wearied little wanderer in God's garden than to learn the way to recognise the difference between the garnishing parsley and its deadly relative whose name is the antithesis of him that is wise, or its still more poisonous effigy, the classic hemlock, growing in shady nooks. We might mention a hundred other instances—e.g., the creeping hairy bryony, with its festooned wreaths of scarlet berries, hard by its rival, the common tamus, with leaves of shining green, growing bronzed and sombre as the autumn of its vegetative life approaches. We could tell that the simple dropwort, or spiræa, has no right to have its title disputed by the water dropwort or the hemlock water dropwort, with which it holds no natural affinity. We could warn against the perfidy of the gaudy foxglove and the sedate but deadly nightshade, and so on; but enough has been written to merit the sympathy of our Board of National Education, and to make them consider that the fields around us are the true fields of learning.

THE MARY WARDELL SCARLET FEVER HOME.

THE first annual meeting of the friends and subscribers of this Home took place on Friday, the 18th inst., at 32, Sackville-street, Piccadilly. Sir J. Risdon Bennett was in the chair. Sir Edward Sieveking, the Rev. J. F. Kittc, and others spoke in support of the institution. In the fifteen months during which it has been open 138 patients have been received—namely, 82 from their own homes, 34 from the London Fever Hospital, 12 from the Metropolitan Asylums Board Hospitals, and 10 from other hospitals. The patients included 16 children of the upper class. Mr. Kitto said that several of his own children had enjoyed the benefits of the Home; one servant, a kitchen-maid, contracted the disease in a mild form. All the cases have done well, and all have expressed a high sense of the comfort and care they received. The terms for ordinary patients are 15*s.* weekly, 10*s.* for children; the terms for ordinary patients are £3 3*s.* a week. More subscriptions and donations are urgently required to complete and maintain this most benevolent work.

RADICAL OPERATION FOR HERNIA.

AN improved operation for the radical cure of hernia has for some time past been practised by Drs. Svensson and Erdmann, surgeons to the Sabbatsberg Hospital at Stockholm. A ligature is applied to the neck of the hernia, and the sac is cut off below the ligature, the contents being previously examined by means of an incision into the sac and returned; or, if only omental, excised together with the sac. In congenital hernias the upper part of the sac only is removed, and where the large bowel is included in the hernia and adherent to the sac wall, this, after being separated from the surrounding tissue, is returned, together with the large intestine, and the rents of Poupart's ligament united by sutures. The dressing employed is iodoform and boracic acid, the wounds being washed with sublimate solution. Since this has been substituted for carbolic gauze, abscesses which used to occur frequently, have become rare. Of the forty-eight cases thus operated on, none of which were selected, thirty-eight were permanently cured—at least no return of the hernia occurred within six

Digitized by Google

months; and in the cases where a return did take place, which amounted to 20 per cent., the condition was very much less painful and distressing than it had been previous to the operation. The Sabbatsberg Hospital has now been opened six years and a half, and during that time 300 cases of hernia have been admitted, about 200 of these being operated on with the knife; a milder procedure, consisting of alcoholic injections, being employed in most of the earlier cases. Not a single case proved fatal, though some of the hernias were very large, some reaching within three or four inches of the knee.

THE HYGIENE OF THEATRES.

GIVEN a spacious theatre, crowded during an evening performance for a period of hours, what is the difference of the effects on its atmosphere produced by the electric light or by gas, particularly as to the temperature and the generating of carbonic acid? Such is the problem which Dr. P. Renk, Professor of Hygiene at Munich, has just set himself to solve. Taking the Theatre Royal of that city, which is lighted by 1400 lamps on the Edison system, he tested the two kinds of illuminants, with the following results: During a representation which lasted from 5 30 P.M. to 10.15 P.M., and which was witnessed by 1790 people, he found that while the rise in temperature in the pit was 11·1° Centigrade with gas, it was only 7·7°, also Centigrade, with the electric light; and that in the upper gallery it was 10·7° with the former, and not more than 7·4° with the latter. As to the increase in the production of carbonic acid, the results were equally important. In the pit it was as 2176 with gas to 1221 with the electric light, and in the upper gallery as 2855 with the first to 1430 only with the second.

THE NEW YORK POST-GRADUATE SCHOOL.

THE Faculty of the New York Post-graduate Medical School have entered upon the fifth year of instruction with the record of a highly successful period behind them, and with increased facilities for the future. No undergraduates are admitted, and no degrees are conferred, but the school is open to all legalised practitioners, and it is available for the young graduate who wishes to acquaint himself with the practical duties of his profession, or for older practitioners who are desirous of taking up some special branch of medicine or who wish to familiarise themselves with modern advances in diagnosis and treatment. The instruction is given by means of clinics, subjects, and specimens. There are no lectures except clinical ones, and no demonstrations without subjects and specimens. It may be safely said that no institution in America designed for graduates in medicine is so completely organised in all its branches, has such accommodation for patients and for instruction, or is so fully equipped with the appliances requisite for each special course as this one; and it is to be hoped that the anticipations of the managers respecting the future prosperity of the school may be fully realised.

BRIGHT'S DISEASE WITHOUT ALBUMINURIA.

A SUBJECT which, it may be remembered, was brought prominently under notice by the late Dr. Mahomed—viz., the occurrence of renal disease without the symptom of albuminuria—was discussed by M. Dieulafoy at a meeting of the Paris Hospitals' Medical Society on the 11th inst. (*Le Progrès Médical*, No. 25). He described four cases, which exhibited for many weeks, or even months, some of the most marked symptoms of Bright's disease, such as vomiting, oppression, headache, œdema of the ankles, the *bruit de galop*, flushing, digital mortification, ocular and cutaneous derangements, and a new sign termed by M. Dieulafoy cryæsthesia—a sensation of extreme coldness limited to the extremities, especially the lower limbs, or to the knees. In not one of these cases was a trace of albumen found in the urine except during the last days of life. Such cases were contrasted with others of so-called "physiological albuminuria." As a means of diagnosis M. Dieulafoy suggests a test which is obviously inapplicable for clinical purposes. It is founded on Bouchard's observation that normal urine is a toxic agent to such a degree that, injected into a vein of a rabbit's ear, it will produce a fatal result when administered in the proportion of 50 cubic centimetres per kilogramme, whereas a much larger quantity (150 and even 285 cubic centimetres) of the urine of Bright's disease is required to produce the same result.

THE LATE PROFESSOR v. GUDDEN.

IN speaking of the melancholy event of the 13th inst., the *Münchener Medicinische Wochenschrift* of June 15th says:—"The death of v. Gudden is an irreparable loss to science as well as to the university; in him we lose one who indisputably ranked among the foremost of modern psychiatrics, one of the most brilliant ornaments of our medical faculty, who as a teacher was esteemed on all sides for his talent as well as for his amiability, and who was a most zealous and energetic associate of our medical societies." Dr. v. Gudden was born at Cleves in 1824, and studied at Berne, Berlin, and Haller. He took his doctorate in 1848, and was appointed superintendent of the Asylums for the Insane at Wemeck in 1855. In 1869 he was made Professor of Psychiatry at Zurich, and in 1872 was transferred in the same capacity to Munich.

CHOLERA INTELLIGENCE.

THE cholera intelligence from Italy is this week the reverse of reassuring. It is true that, though the disease is still maintained at Venice and at Bari, the daily number of cases and fatal attacks has undergone a diminution, but still the infection has now clung to those places for a lengthened period, and such sanitary precautions as may have been adopted have failed to get rid of a danger which steadily increases with the approach of the hotter months. And not only so, but some further extension of the area infected has taken place. To the north, cholera has appeared at Codigoro, in the province of Ferrara, on the low-lying flats to the south of the estuary of the river Po. So also, two cases and a death are reported from Udine, the frontier town between Austria and Italy. This is not the first appearance of the disease there this year, and the occurrence gives rise to some fear that there may be a tendency for a diffusion in the direction of Austria and Hungary. Trieste is also, in so far as the imposition of quarantine restrictions is concerned, still regarded as an infected port. As regards the south, no new locality is known to have been invaded, but the cholera returns, which had ceased as regards Brindisi, are again issued, two fatal attacks having been reported on the 20th and the 21st of June.

LYMPHADENOMA OF THE INTESTINE WITH LEUKÆMIA.

M. MATHIEU reported at the last meeting of the Paris Anatomical Society the case of a man, aged sixty, who had suffered from uncontrollable diarrhœa for five or six months, with glandular enlargements in the groin and axillæ. He was very cachectic, and anasarca was present. The blood was examined several times, without any signs of leukæmia being detected. At the necropsy the solitary glands were found much swollen and of a pearly white colour, Peyer's patches being healthy. The mesenteric glands were much enlarged, also the spleen, the liver and kidneys being healthy. No tubercle was found.

THE DWELLINGS OF THE PEOPLE.

THE Mansion House Council on the Dwellings of the People have again, in their latest report, drawn attention to some of the defects in our municipal system, which, in spite of the ample exactitude of law, continue to impede the advance of sanitation in the more crowded parts of London. They have little to say against the law as it stands, much in its favour. The difficulty lies in the weakness of the executive as represented by the inspectors and medical officers, but, above all, in the personal and proprietary interest of vestrymen in the dwellings whose condition is in question. In spite of the hindrances which their work has thus encountered, the Council have been able, through their voluntary aid committees, to do much for the improvement of insanitary dwellings. In order to secure still further the accomplishment of this very desirable object by the official sanitary staff, they suggest that certain obvious reforms should be adopted in the organisation of that body. With regard to inspectors, the number of whom at present varies from 1 in 50,000 to 1 in 100,000 of the population, they rightly assert that they are absurdly few, that a stronger guarantee of special sanitary education than is now provided should be required of them, and that they should follow no other calling. In speaking of medical officers, they draw attention to the fact that the hands of these gentlemen, as well as of the inspectors, are apt to be tied, and their reforming zeal discouraged by the opposition of the vestrymen, to whom they are responsible. The Council accordingly advise, with much justice, that the Local Government Board should be required to confirm the appointment or removal of medical officers and inspectors, without, of course, prejudicing the right of the vestries to elect their own officers subject to that authority. Vestrymen, according to the report, are frequently found to be very indifferent guardians of the public health. Their fitness for office in other particulars, indeed, is in some, perhaps in many, cases but little regarded by their constituents. We are well aware that there are also many localities where public intelligence is more careful in its selection, but the fact that well-informed parochial oversight is apt to be most wanting where it is most required, in the poorer districts, is itself evidently suggestive of the need that the sanitary service should be under a higher central control.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

AT the approaching meeting at Birmingham, commencing on September 1st, the organising committee of Section A has arranged that a special discussion shall be held, jointly with Section D, on the physical and physiological theories of colour-vision. The discussion will be opened by Lord Rayleigh, and Dr. Michael Foster will also take part in it. Persons who wish to contribute papers bearing on the subject of discussion should send their names to the recorders of Sections A or D, at 22, Albemarle-street, W., not later than August 1st.

PROVISION AGAINST INFECTIOUS DISEASE.

A RECENT occurrence in Darlington should serve as a warning to all towns that are without a machinery sufficient for dealing with cases of infectious disease. Local authorities frequently neglect to make complete provision until disease has appeared, and even threatened to assume serious proportions. So in Darlington there was a hospital for the reception of infectious cases, an ambulance to remove the sick, but there was no horse to be used in connexion with it. A man who had been staying at several lodging-houses in the town was attacked with small-pox, and being practically turned out from the last of these places on the ground that he was "not all right," he wandered about until he fell down in the Skinnergate. There a crowd collected round him, and he remained until Dr. Manson was called, and under his instructions the ambulance was sent for; but owing to the difficulty of obtaining a horse the man remained for an hour and a half in the street, exposing many people to serious risk. It is more than likely that the economy which prevented a horse from being kept in readiness will cost a larger sum of money than would have been thus spent, and cause some loss of life. The subject was discussed at a meeting of the board of guardians on Monday, when a statement was made by the master of the workhouse that a nurse in this institution had contracted small-pox from another case of this disease which had been admitted some three weeks before.

HISTORY REPEATS ITSELF.

THE reputed discoverer of a new fact or idea is probably never the first to have made the discovery, or even to have formulated it. In the world of ideas, as in that of material, a continuity can be perceived by which new ideas are evolved from old ones, as new forms of life are the children of ancient forms. Hence it is not surprising to hear that to M. Pasteur does not belong the credit of discovering that zymotic diseases are due to germs. It appears that more than a century and a half ago Dr. Goiffon wrote a work on the origin of the Plague, in which he advanced the theory that the disease was dependent on minute insects or worms, which had none the less a real existence, though they were then beyond the powers of the microscope to reveal. Dr. Goiffon also had something to say on the process of infection, which he likewise considered to be the work of minute living creatures that conveyed infection in a latent condition from one place to break out afresh in another. Did not Goiffon get the idea from some still more ancient master?

SEWAGE FARMS NEAR PARIS.

ON former occasions we have pointed out the hostility with which all propositions to drain direct into the sewer have been met by the Parisian population. Custom and prejudice, united with the more scientific objection that the sewers of Paris are only fit to receive rain-water, have prevented the advocates of the "tout à l'égout" from realising their proposals. But now the opposition has extended to the districts outside Paris. One of the worse features of the drainage scheme is that the main sewer falls into the river Seine, which is already very foul. To avoid further pollution it is proposed to enlarge considerably the sewer farm of Gennevilliers, and to devote a portion of the forest of St. Germain to the purification and filtration of sewerage-water. For this purpose an official Commission, consisting of members of the Paris Municipal Council and engineers of the town, went to visit the districts in question. On landing from the river steamer at Bougival, the Commission was met by the mayors and municipal councillors of the communes of Rueil, Chatou, Croissy, Bougival, le Pecq, Marly, le Vésinet, and other places, who all energetically protested against any extension of the sewerage farms. When the Commission reached the forest of St. Germain they found a crowd of some 2000 persons waiting for them. These demonstrators had inscriptions written on sheets of paper or squares of cardboard, stating that they strongly objected to the project. Some demanded that the sewer should be prolonged to the sea. The greatest excitement was displayed, and many ladies participated in the manifestation; some even had their written protestations suspended from their necks. For five hours the crowd dogged the footsteps of the Technical Commission, who were only too glad, after

Digitized by Google

this hostile reception, to return to Paris. It will now be more difficult than ever to bring the vexed problem of the disposal of sewage to a satisfactory conclusion. In spite of the reclamations made by the demonstrators, Paris is too far inland to drain into the sea; evidently the suburban inhabitants will not tolerate sewerage farms, and, of course, it is against every sanitary law to allow a compact population of 2,000,000 people to drain into a small river like the Seine. Under all these circumstances Paris seems indicated as a town which should have a double system of drainage. Rain-water might continue to flow through the present large and defective sewers into the Seine; but sewage proper should be collected in a small separate canalisation, conveyed out of town, and there treated in hermetically closed tanks and reservoirs. Such a solution of the difficulty would probably not occasion any popular outcry or opposition.

"FAITH-HEALING" DISCUSSED.

ANY who may be interested in "faith-healing," whatever their views, will do well to look through an article in the *Century* for this month, in which the subject is carefully and impartially examined. Other systems in which the influence of will plays a part, assisted by an element of faith in the medium of its action, receive due attention. Miracles reported to have occurred in recent times at the hands of faith-inspired persons are compared and contrasted with those recorded in Scripture. While we do not care to accept as proof every diagnosis of disease related by the author in cases of "mind-cure," we agree with him that this doctrine implies no real miracle, but the tonic influence of an awakened will and hope in the sufferer from functional disease, and such disease only. The discussion is conducted in a moderate and tolerant spirit, and its manner and matter are alike calculated to adjust the focus of public opinion on the topic in question.

WHAT IS COURAGE?

FROM time to time the notion crops up, and finds expression in many of our contemporaries, that death from hydrophobia is due to fright; that the victim of a bite from a rabid dog succumbs because he does not struggle against his fears. As a personal quality, courage may be well known to every individual, but what it is physiologically would certainly puzzle wiser heads than Bacon's to propound. One thing seems to be certain, that this emotional (or is it intellectual?) state has its chief seat in the highest parts of the brain. Probably, not even the advocates of the courage treatment of hydrophobia would gainsay the fact that the chief seat of the morbid process in hydrophobia is somewhere in the brain beneath the seat of courage. Now, it is notorious that the higher parts of the brain can in large measure resist or hinder the actions that take place in the lower. And there might be some reason for asking whether it is not possible for an action or state like courage to influence, either in repressing or augmenting an action, like that of hydrophobia, which takes place below it. Many epileptics are able at the onset of a fit, when this is attended by a warning, to stop the attack either by a mere effort of will, often aided by voluntary muscular contraction with its necessary attendant sensations, or by some direct powerful impression on one or other of the senses. But there is a limit to such powers. No man can permanently arrest the action of breathing, and the same may be said generally of the heart's action. And it is precisely in the neighbourhood of the centres that preside over the action of breathing, the heart, and deglutition, that the morbid process of hydrophobia goes on in its course. If hydrophobia can be checked [illegible] resulting from strychnia poisoning ought to be capable of voluntary control, for there is a close analogy between the two affections. No; courage is a powerful remedial agent, but it cannot prevail against a germ disease that directly attacks the immediate vicinity of the vital centres, the mere pin-pricking of which, as was shown years and years ago by Flourens, inevitably terminates in death.

THE MICROBE OF RABIES.

THE cause of rabies, which has long been regarded as a vital agent, has hitherto eluded the grasp of the microscopist. We say this notwithstanding the description of its microbe by M. Paul Gibier a few years ago and by M. Fol last year, for bacteriologists and others have not accepted their observations. But Mr. G. F. Dowdeswell has, it appears, distinctly discovered a micrococcus in the nervous tissues of rabid animals that will probably be found to be the cause of the disease (*vide* THE LANCET, p. 1112). There is some difficulty in staining the micrococcus, which is not nearly so minute as Fol made out. We believe that Mr. Dowdeswell is about to attempt its cultivation.

WHAT IS A TEETOTALER TO DO WITH HIS PORT?

THE papers have been all relating the troubles of a good man, Mr. Green, of Bishopswood House, Highgate, with 2500 bottles of port in his cellar, valued at £600, and who finally, and after considering the three courses open to him, as to all men, poured the wine into the sewers. We must all admire the motive that impelled to this action. But the action itself is not so clearly entitled to admiration. The wine should have been given to hospitals. It is allowed to be of use as medicine, and the course must be considered open to the charge of waste. The question in casuistry is not entirely new. A well-known physician is understood to be somewhat perplexed with it. There are instances where the offending alcohol is best thrown into the sewers, and that promptly; but the present is not one of these.

EPIDEMIC DISEASES IN PARIS.

Il Morgagni (June 5th) observes that, whereas in well-administered cities mortality from preventable diseases has been on the decrease in recent years, it has, on the contrary, steadily risen in Paris. This has specially been the case with diseases closely connected with drainage and drinking-water—diphtheria and typhus. Dr. Hertillon has tabulated the mortality per thousand inhabitants, and proved that within the last ten years the percental ratio of deaths from the two diseases named has nearly doubled. Without insular pride, English sanitarians may reasonably congratulate themselves that *all* things are not done better in France.

UNIVERSITIES OF EDINBURGH AND ST. ANDREWS.

WE understand that it is not the intention of Mr. Ericlsen to contest the representation of these universities at the coming election. Some months ago he was requested to stand again in the event of a dissolution or of a vacancy occurring, but with much regret declined to do so. There will consequently, we believe, be no opposition offered to the re-election of Mr. Macdonald, the present member.

THE isolation of cocaine, according to Professor Torretti in the *Raccoglitore Medico*, was first effected in the laboratory of the Botica y Drogueria Boliviana by Signor Pisani in 1857. The research was suggested to him by the celebrated Austrian traveller Tschudy, and Dr. Aquiles Reid of Valparaiso is said to be in possession of Pisani's confirmatory manuscripts.

Digitized by Google

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of May, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies exhibited in every case a very marked diminution, as compared with the previous month, in the proportion of organic matter present. Of the water drawn from the Lea, that supplied by the New River Company contained less organic matter than any of the other river waters, whilst the East London Company's supply resembled in this respect the Thames-derived waters. All the waters were clear and bright on delivery.

IN reference to the excessive mortality amongst our troops in Egypt, to which we alluded in our last issue, the *Egyptian Gazette* publishes the following figures:—The Assouan garrison consists of about 3000 men, of whom 250 are under twenty years of age, 660 are from twenty to twenty-one, 1160 are from twenty-one to twenty-three, and 950 are over twenty-three. The deaths during May numbered fifty-two, mostly from enteric fever. Between the 13th and the 16th there were twenty-eight cases of heat apoplexy, from which malady five deaths occurred on the 16th.

THE sum of £2000 has been placed by Mr. George Holt in the hands of the treasurer of University College, Liverpool, to provide, for the next ten years, two scholarships annually, each of the value of £100, tenable for a year. To these the Medical Faculty of the College will nominate senior students who have been conspicuous for diligence and ability during the whole of their previous course, and who it is desirable should continue their studies for another year.

ON May 10th Professor Luigi Vella expired, after two years' disablement by nervous disease. Up to that time he had occupied the chair of physiology in the University of Bologna as a colleague and very intimate friend of the distinguished Ercolani.

THE death occurred last week at Cambridge, in the eighty-eighth year of his age, of Mr. Richard Potter, M.A., L.R.C.P., formerly Fellow of Queen's College, Cambridge, and Emeritus Professor of Natural Philosophy and Astronomy in University College, London.

PROFESSOR KAPOSI of Vienna has succeeded the late Professor Auspitz as joint editor (with Professor Pick) of the *Archiv für Dermatologie und Syphilis*.

TUBERCULOSIS IN CATTLE.

A VALUABLE report has been presented to the Parliament of Victoria by a "Board appointed to inquire relative to the existence and extent in Victoria of the disease in cattle known as tuberculosis, whether its existence is likely to be detrimental to the public health, and what preventive measures should be adopted." The report is fully exhaustive of the subject, comprising sections upon the prevalence of tuberculosis, its communicability, the doctrine of the bacillus, and Koch's investigations concerning it, with statements in support of and opposed to Koch's views, the question whether tuberculosis is a contagious disease, the limited nature of its infective power, the hereditary tendency to tuberculosis and hereditary transmission, the identity of human and bovine tuberculosis, and the question whether the flesh of tuberculous cattle or the milk of tuberculous cows is fit for food. The opinions at which the Board arrived are given in a summary, which, as the result of a prolonged and painstaking inquiry, is instructive and important, besides placing the question in a clear and definite light.

Bovine tuberculosis and human tuberculosis, though differing widely in the general appearance of the lesions which they present after death, and though differing also in a less degree in their history during life, are yet essentially allied to each other; they are produced by the action of the same low vegetable organism, the *bucillus tuberculosis*, which is found in all forms of tubercle, in whatever animal developed. These organisms may be cultivated in the pure state, generation after generation; if such pure cultures, far removed from their original source, be inoculated into susceptible animals, such as rabbits and guinea-pigs, disseminated tuberculosis is set up in the various organs and tissues of the animals operated upon; and in the tubercles so produced similar organisms are again found. These results are invariable; whether the pure cultures are introduced beneath the skin, into the abdominal cavity, or into the anterior chamber of the eye, tuberculosis follows with certainty in all susceptible animals; and even with animals usually insusceptible like results are obtained if a larger number of organisms be introduced, so as to overcome the resistance of the tissues. Moreover, when animals are fed with tubercular matter, whether derived from human or from bovine tuberculosis, a large proportion become tuberculous, and this result is not prevented if the animals be well housed and otherwise well fed. There is also evidence of no slight weight tending to prove that the milk of tuberculous animals, even when the udder is not affected, may induce tuberculosis in other animals to whom it is administered as food; and this, too, although abundance of sound milk or other suitable food is given at the same time. Other evidence, not quite so conclusive, but sufficiently cogent, indicates that the flesh of animals suffering from advanced and widespread tuberculosis may induce tuberculosis in animals fed upon it unless the flesh be thoroughly cooked. It has also been found that if tuberculous matter containing the specific vegetable organisms be suspended in water and repeatedly sprayed into the atmosphere of a chamber in which comparatively insusceptible animals, such as dogs, are kept, tubercles develop in the lungs and sometimes in other organs. Furthermore, when a large number of animals are kept in the same room, but in different cages, some being artificially infected with tuberculosis, and others being simply kept as "control" animals for the purpose of comparison, cases of apparently spontaneous tuberculosis appear from time to time among the "control" animals. The greater the number of tuberculous animals in the room, the more numerous will be the cases of spontaneous tuberculosis; but no "control" animal has been known to become tuberculous until it has been for some months in the infected apartment. The spontaneous tuberculosis so induced affects chiefly the lungs and bronchial glands, and bears a close resemblance to the ordinary phthisis of man.

The specific organisms, or bacilli of tubercle, are present in the sputa of phthisical patients, sometimes in great abundance; and they have been collected from the air issuing from wards containing large numbers of consumptive patients. Phthisical sputa may be dried and powdered and kept in this state for months without destroying the vitality of the bacilli.

Numerous cases are on record in which tuberculosis has apparently been communicated from one animal to another, and from one human being to another when living in close relations with each other. The insidious commencement and the long course of the disease render it difficult to trace such communication. But while the possibility of such direct communication has been sufficiently established, it is also true that exposure to contagion, even for considerable periods, is comparatively seldom followed by the development of tuberculosis. This fact is explained in two ways: Firstly, the specific organisms multiply very slowly, and only when protected from much mechanical disturbance; and they cannot, unless in very exceptional circumstances, multiply at all outside the living body, owing to the narrow limits of temperature within which they flourish. Secondly, they cannot with equal certainty attack all varieties of animals, or even all individuals of the same variety without distinction; thus, guinea-pigs and rabbits are very susceptible, ruminants and men are moderately susceptible, while dogs are comparatively insusceptible. The moderately susceptible animals appear to be secure against the inroads of small numbers of the bacilli

Digitized by Google

unless they are specially predisposed. This predisposition may be general or local; a general predisposition consisting in some frailty of constitution, often inherited, and a local predisposition generally produced by the effects of inflammation in some organ, weakening its vitality and leaving within it some stagnant or semi-stagnant exudations or secretions, in which the bacilli find a congenial soil for their development. Above all, the occurrence of repeated catarrhal inflammations of the lungs appears to create the special predisposition which is necessary to enable the bacilli to maintain themselves and multiply within the body.

Lastly, heredity certainly plays a most important part in the propagation of this disease. Tuberculous parents often bequeath to their offspring an original frailty of constitution which renders them liable to be infected by the bacilli; and, in the second place, though the truth of this is not well established, it is possible that the germs of the disease may themselves be transmitted from parent to offspring, and, after lying latent in the system for a variable time, may subsequently, under favouring circumstances, wake into new activity.

Numerous experiments have proved that tuberculosis may be transmitted from man to lower animals, and from one lower animal to another. In the necessary absence of experiment, the evidence in favour of its transmission from lower animals to man may appear less cogent; but in the opinion of this Board the evidence is amply sufficient to justify legislative precautions.

These precautions, as embodied in the recommendations of the Board, include the declaration of tuberculosis as a contagious disease, and its introduction into the schedule of the Diseases of Stock Act, so that tuberculous animals may be seized and slaughtered; but it is not proposed to introduce any quarantine regulations. No compensation is to be allowed to owners for the compulsory slaughter of tuberculous cattle; and it is further recommended that a circular letter be addressed to owners of stock, requesting their active co-operation with the Government, so as to limit the prevalence of tuberculosis, and indicating the measures most effective to this end. Further recommendations are made respecting tuberculosis in reference to meat-supply, and dairies, which it is proposed to inspect. There can be no question that the Board have gone to the root of the matter, and it remains to be seen how far it is possible to carry their recommendations into effect in view of the great prevalence of bovine tuberculosis.

DR. RICHARDSON'S LECTURES ON ANIMAL OR VITAL MECHANICS.

LECTURE V.

MECHANISM OF THE HEART.

THE fifth and last lecture of the course delivered on Monday, May 31st, was devoted to the subject of the work of the heart. The circulation through the heart itself was first noticed, and the provision by which it is secured that the heart shall be fed with blood permanently, as the primary organ of the circulation, and in that sense the organ which requires to be served before any muscle of the body, voluntary or involuntary. In the second part of the lecture Dr. Richardson described the movements of the auricles and the ventricles, the diastoles and systoles, and the valvular actions during each series of movements. In this part he explained that he had seen the heart working under two distinct tensions, which he designated as the high or full vital tension and the low or syncopal tension. Under the high or full tension, the volume of the heart is large and the stroke so powerful as to distend the whole of the arterial trunks; under the low tension, the volume of the heart is reduced to fully half that of the high tension, and, although the motion of the auricles and ventricles is still in correct order as to time and method, the propulsion is so feeble that the arteries are not distended. In this minor condition of action the circulation is sustained, as during syncope and catalepsy, but in a passive or negative state, from which the revival is sometimes all but instantaneous, owing to a sudden return of the heart to its full power. In an experimental observation under anæsthesia, the lecturer had actually witnessed in a lower animal this transition in the work of the heart from the low to the high tension. It was the work of a moment, was attended with phenomena resembling a restoration from temporary death to active life, and was due probably to a restored balance of the nervous supplies by which the heart is naturally maintained in equilibrium of motion.

The observation on the equilibrium of motion led to a description of the nervous supplies of the heart: the propelling from the sympathetic source: the controlling, through the pneumogastric, from the cerebro-spinal source. Here Rudinger's dissections of the cardiac nerves formed on the screens beautiful illustrations, rendering the demonstration of a difficult subject extremely easy and practical. From this point the course of the lecture was more thoroughly mechanical. The number of the pulsations of the heart in different animals—in fish, frog, bird, rabbit, cat, dog, sheep, horse—was described, and a few comments made on the remarkable slowness of the heart—40 strokes per minute—in the horse. Then the number of pulsations in man at various periods of life, and at different levels, from the level of the sea up to four thousand feet above sea level, was brought under review, and was followed by a computation of the average work performed by the heart in a healthy adult man. The work was traced out by the minute, the hour, and the day, and was shown to equal the feat of raising 5 tons 4 cwts. one foot per hour, or 125 tons in twenty-four hours. The excess of this work under alcohol in varying quantities formed a corollary to the history of the work of the heart, Parkes' calculation showing an excess of 24 foot-tons from the imbibition of eight fluid ounces of alcohol. The facts relating to the work of the heart by the weight of work accomplished was supplemented by a new calculation, in which the course of the circulation was explained by mileage. Presuming that the blood was thrown out of the heart at each pulsation in the proportion of 69 strokes per minute, and at the assumed force of 9 feet, the mileage of the blood through the body might be taken at 207 yards per minute, 7 miles per hour, 168 miles per day, 61,320 miles per year, or 5,150,880 miles in a lifetime of 84 years. The number of *beats* of the heart in the same long life would reach the grand total of 2,869,776,000.

In the next part of the lecture the sounds of the heart were described and imitated, and the muscular construction, with special reference to the spiral character of the cardiac action, was illustrated on the screen by the electric light from Pettigrew's remarkable series of photographs of dissections of the heart. The effect of the ventricular contraction on the arterial pulses was also illustrated by a series of sphygmographic tracings thrown on the screen, showing the natural pulse tracings and the various deviations from the natural under the effects of alcohol, tobacco, opium, and exposure to extreme cold. The resistance produced by cold was illustrated from the tracing of the pulse of Mr. Fleuss after his immersion for an hour in water at 35° Fahrenheit.

The course was brought to a close with a short summary of a few of the leading topics which had formed the subjects of discourse, and with some practical hints deducible from them.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Harwich Urban District.—The birth and death rates for this district during 1885 were 39·5 and 15·9 per 1000 respectively, and there was a marked absence of any prevalence from infectious diseases; two cases were, however, admitted into the isolation hospital. Mr. Hardwicke, in speaking of disinfectants, places great confidence in one which for commercial purposes is sold under a special name: but something more than a chemical fluid, however trustworthy, is needed for the purposes of a sanitary authority who have bedding &c. to deal with. A new water-supply from borings in the chalk is expected to be delivered into the borough next October.

Hanley Urban District.—This district exhibited in 1885 a death-rate of 3·2 per 1000 below that of the mean for the

Digitized by Google

preceding five years, the rate being 19·1. But there is room for still further improvement in this respect, for the infant mortality under one year of age still reaches as high a rate as 198 per 100 registered births. An attempt has been made to secure a voluntary notification of infectious diseases, and to a certain extent it has been successful; but it is added that three medical men have refused to accede to the request to notify, and since any such objection to report does away with the efficiency of the scheme, we fear that, as in other similar cases, the result may end in failure. Whether the refusal to co-operate was due to the inadequacy of the fee offered or to other causes is not stated. Dr. Walker points out that every district stands in need of a hospital for the isolation of first cases of infection, and it is to be hoped that Hanley will endeavour to deal, by isolation, with all the cases of the infectious fevers with which the authority will become acquainted, and with which it can properly so deal.

Tunbridge Wells Urban District.—From a statistical point of view, Tunbridge Wells has a high reputation. For five years past its annual rate of mortality has only varied between 14·0 and 15·7 per 1000, and in 1885 it was 15·4. The so-called zymotic rate also stood as low as 0·8 per 1000. The only fatal diseases coming directly within sanitary control which took place were 4 from continued fever and 2 from diphtheria. Not much is said as to the sanitary conditions prevailing in the town, but inspections are evidently carried out with care and regularity, and the isolation hospital is systematically used. Thus, 23 cases of mild scarlet fever, and 9 cases of small-pox, the result of imported infection, were all dealt with in this way.

Kendal Urban District.—Kendal, with a population of 13,800, has a death-rate of 18·5 per 1000; but it had not a single death from enteric or typhoid fever during the past year. This certainly affords a satisfactory comparison with previous years that are now well-nigh forgotten; for in five epidemics between 1838 and 1860 the deaths from "fever" ranged from 48 to 117. Since 1860 there has been an almost steady diminution in the mortality of epidemics that have ensued, and with sanitary progress it may be hoped that such mortalities will before long cease. Some of the diminution of death from infectious diseases has corresponded with the provision of the borough sanatorium, which is regularly used, the patients' friends in certain cases making payments towards the cost of maintenance. Indeed, the sanatorium has been so useful that, by Mr. Paget's advice, a second pavilion has been erected, and there are now, in full working order, means for the isolation of two diseases in both sexes. Disinfection is also regularly carried out, 380 articles having been so dealt with in 1885.

Wavertree Urban District.—Hitherto the means of isolation used for this district has been the Netherfield-road institution, but the intended acquisition of this building by the Liverpool Corporation should, as Dr. Harvey points out, lead to the provision of a local hospital belonging to the authority. That may, of course, be arranged jointly with one or other of the neighbouring districts, which need similar accommodation. During 1885, 19 cases of scarlet fever, 15 cases of diphtheria, and 5 of small-pox came under notice; and it needs little more than this record to prove the need that exists for some available means of isolation. General sanitary inspection of the district is evidently carried out, and some of the amendments which are called for are specified in the report. The death-rate for 1885 was 14·8 per 1000, and the birth-rate was 34·0. The children under one year of age died at the rate of 11·5 per cent. of the registered births.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5068 births and 2927 deaths were registered during the week ending June 19th. The annual death-rate in these towns, which had ranged in the preceding thirteen weeks from 29·3 to 17·0 per 1000, further declined last week to 16·8, and was lower than the rate in any week since the third of September, which was the lowest on record. During the first eleven weeks of the current quarter the death-rate in these towns averaged only 18·9 per 1000, and was 3·1 below the mean rate in the corresponding periods of the ten years 1876–85. The lowest rates in these towns last week were 10·9 in Birkenhead, 11·9 in Sunderland, 13·1 in Derby, and 13·4 in Brighton. The rates in the other towns ranged upwards to 21·8 in Plymouth, 22·0 in Oldham, 26·8 in Blackburn, and 39·6 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had in recent weeks declined from 430 to 265, rose again last week to 293; they included 89 from measles, 60 from whooping-cough, 59 from diarrhœa, 35 from scarlet fever, 29 from "fever" (principally enteric), 21 from diphtheria, and not one from small-pox. No death from any of these zymotic diseases was recorded last week in Norwich, Derby, or Birkenhead; whereas they caused the highest death-rates in Portsmouth, Blackburn, Bolton, and Preston, in each of which towns measles again showed epidemic prevalence. The greatest mortality from whooping-cough occurred in Oldham, Preston, and Wolverhampton; and from diarrhœa in Halifax, Blackburn, and Preston. The 21 deaths from diphtheria in the twenty-eight towns included 16 in London and 2 in Birmingham. Small-pox caused 1 death among the residents of London and its outer ring, and not one in any of the twenty-seven large provincial towns. The number of small-pox patients in the metropolitan hospitals situated in and around London, which had been 29 and 31 on the preceding two Saturdays, had declined to 21 at the end of last week; 2 cases of small-pox were admitted to these hospitals during the week, against 5 and 9 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 179 and 216 in the preceding two weeks, declined again last week to 184, and were 57 below the corrected average. The causes of 61, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Nottingham, Sunderland, Brighton, and in seven other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Bristol, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had slowly declined in the preceding seven weeks from 23·1 to 20·9 per 1000, rose again to 21·7 in the week ending June 19th; this rate exceeded by no less than 4·9 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 17·3 and 17·4 in Paisley and Greenock, to 20·8 in Edinburgh and Aberdeen and 24·4 in Glasgow. The 536 deaths in the eight towns showed an increase of 20 upon the number in the previous week, and included 18 which were referred to whooping-cough, 17 to measles, 8 to scarlet fever, 8 to diarrhœa, 5 to "fever," 1 to small-pox, and not one to diphtheria; in all, 57 deaths resulted from these principal zymotic diseases, against 68 and 49 in the preceding two weeks. These 57 deaths were equal to an annual rate of 2·3 per 1000, which exceeded by 0·6 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 21 and 19 in the previous two weeks, further declined last week to 18, of which 15 occurred in Glasgow and 2 in Aberdeen. The deaths from measles rose again last week to 17, from 19 and 10 in the previous two weeks, and included 8 in Edinburgh and 7 in Leith. The mortality from measles in Edinburgh, which has been so excessive since the middle of February last, shows but slight sign of abatement. The 8 deaths from scarlet fever exceeded the numbers in the previous two weeks; 4 were returned in Glasgow and 2 in Dundee. The deaths attributed to diarrhœa, although slightly exceeding the number in the previous week, were 4 below the number in the corresponding week of last year, and they included 4 in Dundee. The 5 deaths referred to "fever," of which 2 occurred in Glasgow and 2 in Edinburgh, were considerably below the average. The death classed to small-pox occurred in Glasgow, and was certified as chicken-pox. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 90 in each of the previous two weeks, rose last week to 93, and were within one of the number in the corresponding week of last year. The causes of 73, or 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 26·2 and 20·8 per 1000 in the preceding two weeks, rose

Digitized by Google

again to 22·9 in the week ending June 19th. During the first eleven weeks of the current quarter the death-rate in the city averaged 25·9 per 1000; the mean rate during the same period did not exceed 17·5 in London and 19·6 in Edinburgh. The 155 deaths in Dublin last week showed an increase of 14 upon the number in the previous week, and included 7 which were referred to the principal zymotic diseases, against 9 and 5 in the previous two weeks; 3 resulted from "fever" (typhus, enteric, or simple), 2 from diarrhœa, 1 from scarlet fever, 1 from whooping-cough, and not one either from small-pox, measles, or diphtheria. These 7 deaths were equal to an annual rate of 1·0 per 1000, the rates from the same diseases being 1·5 in London and 2·7 in Edinburgh. The 3 deaths from "fever" showed an increase upon the numbers in recent weeks, while the fatal cases of whooping-cough were fewer than in any previous week of this year. Six inquest cases and 9 deaths from violence were registered; and 63, or more than a third, of the deaths were recorded in public institutions. The deaths both of infants and of elderly persons showed an increase upon the numbers in the previous week. The causes of 14, or 9 per cent., of the deaths registered during the week were not certified.

CHOLERA IN SPAIN IN 1885.

An official statistical report on the cholera epidemic in Spain in 1885 has recently been issued in Madrid. It appears that the cases reported in the entire kingdom were 338,685, of which 119,620, or more than 35 per cent., proved fatal. These 119,620 deaths were equal to a rate of 7·0 per 1000 of the population of the kingdom, which is more than double the rate from the same cause in England and Wales during the epidemic of 1849, which was 3·0 per 1000. Spain for administrative purposes is divided into 9304 communes. The whole of the cholera epidemic was confined to 2247 of these communes, having an aggregate population of about 6,500,000 persons. The death-rate from cholora in the portion of the kingdom actually invaded by the epidemic was equal to 18·2 per 1000 of the population. It follows that 7067 communes, with an aggregate population of rather more than 10,000,000 persons, enjoyed complete immunity from the disease, so far as appears from the report just issued. No information is given as to the varying mortality from the disease in the large towns of Spain, the statistical unit in the return, so far as detailed figures are concerned, being the commune, the communes making *partidos judiciales*, or subdivisions of provinces. It is evident from the tables that the disease was most fatal in the urban portions of the population, while a large proportion of the rural population escaped attack. The death-rates exceeded 30 per 1000 of the population in the attacked portions of the provinces of Castellon, Valencia, Saragossa, and Ternel. It is worth noting, however, that, so far as the tables afford the means of judging, the largest towns of Spain did not suffer severely from the disease; in the commune of Madrid the cholera death-rate did not exceed 2·7 per 1000, in Barcelona 5·4, in Seville 0·0, and in Cadiz 9·2. The first cases of the disease appeared early in February in the province of Valencia, and the disease lingered in different localities until the close of the year; indeed, it is noted that the last cases of the epidemic were reported towards the end of March in the province of Cadiz. In addition to the proportions of deaths from cholera to the population in the various subdivisions of the country, the report also gives the proportions of deaths to the numbers attacked. Such statistics are generally of very doubtful statistical value, and it is improbable that in Spain the figures are more trustworthy than is usually the case. It has been noticed that the proportion of deaths to cases in the whole country is reported to have been 35 per cent.; it further appears from the tables that in the various provinces the recorded proportions varied from 21 and 23 per cent. in Zamora and Palencie, to 59 in Badajoz and Oviedo, and 100 per cent. in Lugo, where only 16 cases were reported, all of which proved fatal. Without information as to the nature of the machinery by which the statistics of attacks were collected, it would be unwise to base any conclusions on these figures with reference to the varying fatal intensity of the disease in different parts of the kingdom. The publication of this cholera report, with commendable promptness, encourages the hope that the Spanish Statistical Bureau will ere long resume its monthly reports upon the mortality statistics of the whole country, which have now been in abeyance for some time.

HEALTH OF CALCUTTA.

The report of the health officer of Calcutta for the quarter ending March 31st, 1886, shows a low rate of mortality compared with the corresponding period in any of the preceding ten years. The death-rate was 29·7 per 1000 of the population. The reduction has taken place chiefly in fevers, small-pox, cholera dysentery, and diarrhœa; in fevers and cholera the improvement was most marked in February, but the number of deaths began to rise again in March. The health officer considers the low rate from fever in February to have been probably due "to the exceptional dryness, and to the fact that no rain fell." Only four deaths from small-pox were recorded; one of the cases was unprotected, one had been inoculated, and two were not traced.

THE SERVICES.

THE RECENT CAMPAIGN IN BURMAH.

IN a general Order relative to the recent field operations in Burmah received from the Government of India, the Governor-General in Council states that the medical department under Deputy Surgeon-General J. Inch Donnelly, M.D., has proved its complete efficiency under circumstances of considerable difficulty.

The Government of Madras have fully acknowledged the services of the following officers as deserving of notice, and the Governor-General in Council now adds to these commendations an expression of his own appreciation of their services:—Surgeon-General J. Irvine, M.D., Medical Staff, and Surgeon-General M. C. Furnell, Indian Medical Department.

The thanks of the Government of India are given to the following officers and their subordinates for the energetic part taken by them in the equipment of the force:—Surgeon-General C. D. Madden, Medical Staff, and Surgeon-General B. Simpson, M.D., Indian Medical Department.

The name of Surgeon-Major C. Sibthorpe, who was in medical charge of the Headquarter Staff, is mentioned in despatches.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Thos. Henry White, M.D., to be Brigade Surgeon, vice George Scott Davie, M.D., granted retired pay; Surgeon S. Lucas O'Neill resigns his commission.

INDIA OFFICE.—The Queen has approved of the retirement from the service of the undermentioned officers of Her Majesty's Indian Military Forces:—Deputy Surgeon-General William Henry Rean, M.D., Madras Medical Establishment; Brigade Surgeon Christopher Joynt, M.D., Bombay Medical Establishment; Surgeon-Major Richard Thos. Lyons, M.D., Bengal Medical Establishment; Surgeon-Major John Chas. Whishaw, M.D., Bengal Medical Establishment; Surgeon-Major Theophilus Bolton Wright Plunkett Johnston, half-pay, Bombay Medical Establishment. The undermentioned officers have been granted a step of honorary rank on retirement:—Brigade Surgeon John Houston, M.D., Madras Medical Establishment, and Brigade Surgeon Christopher Joynt, M.D., of the Bombay Medical Establishment, to be Deputy Surgeons-General; Surgeon-Major Richard Thomas Lyons, M.D., and Surgeon-Major John Charles Whishaw, M.D., both of the Bengal Medical Establishment, to be Brigade Surgeons.

RIFLE VOLUNTEERS.—3rd Lancashire: Surgeon and Honorary Surgeon-Major John Burns resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement.—3rd Volunteer Battalion, the South Staffordshire Regiment: The undermentioned officer resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement—Surgeon and Honorary Surgeon-Major John Fraser, M.D.

UNIVERSITY COLLEGE HOSPITAL.—A grand bazaar in aid of the funds of this charity will be opened by the Princess Louise in the grounds of University College, Gower-street, on Friday (this day), and will be continued on the following day.

"Audi alteram partem."

ELECTION AT THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—As the bye-laws of the Royal College of Surgeons require me to stand again for election into the Council on July 1st, after two years' tenure of office, I may be permitted to express my hope that the Fellows will continue their trust in me. The Council has met twenty-five times during my membership, and I have attended every meeting. Besides sharing in routine business, I have served on two important committees, one for widening the basis on which the Fellowship may be obtained, the other for considering the question of granting the title of M.D. to Members who have passed the conjoint examinations of the two Colleges. In joining in the work of these committees, I have striven to promote the acceptance of these proposals, which are in my opinion most desirable to bring into operation. By taking part in all discussions, where I believed I could do so usefully, I have endeavoured to instruct myself in the business of the College and to perform the duties entrusted to me. On these experiences I venture to rest my claim for a renewal of the confidence of the Fellows in the coming election. I am, Sir, yours truly,

Wimpole-street, June 22nd. BERKELEY HILL.

TUBERCLE BACILLI IN ADDISON'S DISEASE.

To the Editor of THE LANCET.

SIR,—With reference to Goldenblum's discovery, will you kindly allow me to add a confirmation of Professor Curnow's observation published in your last week's issue? About three years ago I examined the suprarenal capsule from a case of Addison's disease, which, although presenting no pigmentation of the skin, was in all other respects a typical case. One supra-renal capsule was atrophied; the other, the size of a turkey egg, was completely degenerated, except in one corner, where a little normal suprarenal tissue was seen. After examining a large number of sections, prepared by Ehrlich's method, neither I nor Dr. Dreschfeld, whose demonstrator I then was, could find any tubercle bacilli. At the same time, negative evidence such as this does not prove that the affection is non-tubercular, or that bacilli had not been present at a former period of the disease. Tubercle bacilli are usually found not in old degenerated parts, but at the borders where active changes are still going on. In a caseous giant cell, for instance, as Weigert has insisted on, the bacilli are numerous at the borders, where the nuclei are still proliferating, but few in number or entirely absent in the central degenerated portion. So, in the suprarenal capsule, the stage of activity may have already passed, and with it the tubercle bacilli.

I am, Sir, yours obediently,

Westbourne-terrace, W., June 21st, 1886. ROBERT MAGUIRE.

To the Editor of THE LANCET.

SIR,—While working in the laboratory of the late Professor Cohnheim, in Leipzig, in the summer of 1882, I had the opportunity of examining the suprarenal capsules in a case of Addison's disease. By means of the Ehrlich method I was able to discover numerous tubercle bacilli scattered throughout their substance. I regret that I had no opportunity at the same time of examining the other organs of the body in order to ascertain the presence or absence in them of bacilli. My observation, however, of the presence of the organisms in the suprarenal bodies, though hitherto unpublished, was communicated to the Royal Medical Society of Edinburgh in a paper on the "Bacillus of Tubercle," read by me before the Society in January, 1883. The microscopic preparations I have still, but the bacilli are now no longer visible, the gentian-violet with which they were stained having disappeared during the four years which have now elapsed since their preparation.

I am, Sir, yours faithfully,

ARTHUR H. CLEMOW, M.B.

Waterloo, near Liverpool, June, 1886.

INCUBATION OF TYPHOID FEVER.

To the Editor of THE LANCET.

SIR,—Two children left their home in the country to come to a London boarding-school on Jan. 11th. On Jan. 27th, the younger of the two sickened with typhoid fever. It was then discovered that at the village where they lived there was quite an epidemic of typhoid, and that the water-supply of the house had become contaminated. The schoolmaster at once wished to know at what date it could be definitely said that the elder boy had not contracted the disease. Wishing to be quite safe in my prognosis, I replied that, although it was impossible to say exactly, if he remained quite well at the end of three weeks and a half, dating from January 11th, he would probably escape. The younger boy was moved from the school to a house near, and the master kept a most careful watch over the elder one until the three weeks and a half had expired, at which date he seemed in perfect health. My disappointment was great to find that on February 7th, or twenty-seven days from Jan. 11th, he did not feel quite the thing, and his evening temperature was 100°. Up to this date he had taken his food heartily and was in capital spirits. He later on had troublesome constipation, and died of intestinal hæmorrhage. No other boy in the school contracted the disease.

The following is a list of the inmates of this country house who have caught the fever. Where known, I have stated the latest possible date on which the patient could have contracted the disease; of course it may have been contracted much earlier. 1. Younger boy came up to boarding-school on Jan. 11th; recovered; incubation sixteen days. 2. Elder boy came up with No. 1 on Jan. 11th; died of hæmorrhage; incubation twenty-seven days. 3. A sister left home on Jan. 21st to stay with friends; recovered; incubation nine days. 4. A brother left home on Jan. 14th to stay with friends; recovered; incubation sixteen days. 5. The nurse of No. 4; recovered. 6. Cook, who lived at the country house and stayed there throughout; recovered. 7. A servant, who came up from the country house, and being taken ill was sent to a cottage hospital near, where she was said to be suffering from scarlet fever and sent on to the fever hospital, but on inquiry I found it was a simple case of typhoid; recovered.

I am, Sir, yours truly,

J. LANGTON HEWER, M.B. Lond.

Highbury New Park, N., June, 1886.

WHOOPING-COUGH.

To the Editor of THE LANCET.

SIR,—I had no intention, nor have I now, of denying the accuracy of Dr. Donkin's history, but I wished to point out the acknowledged difficulty of isolation, especially in the convalescent stages, of the exanthematous fevers, and the possibility of infection from some external source, unknown and undreamt of by the medical attendant. I have known the contagion of pertussis to be apparently carried by foul linen, handkerchiefs, napkins, &c., and to result in whooping-cough after the usual period of incubation; and when we consider how easily contagion might be so conveyed, without a suspicion arising before the mind of the medical attendant, I am rather inclined to attribute these cases to some such unwholesome cause than to an exceptional deviation from the general law. With regard to the frequency of whooping-cough as a sequence of measles, I am quite at one with the writer, and have explained in my paper the manner in which this and probably other exanthemata act.

I am, Sir, yours &c.,

Manchester, June, 1886. W. H. BARLOW.

ELECTROLYSIS OF STRICTURE OF THE URETHRA.

To the Editor of THE LANCET.

SIR,—At the same time that I would acknowledge the importance of Mr. Bruce Clarke's courteous criticism of my letter upon the above subject in THE LANCET of June 5th, I would submit that he has not accurately guaged the careful wording of my first paragraph. He believes that it implies that he has used *strong* currents in the electrolysis of stricture. Now I had especially guarded against this inference being drawn, by using comparatives. I described the

Digitized by Google

currents he employed (10 cells) as being *stronger*, in contrast to those which I had used (3 cells) as being *weaker*. This was my only method of comparison, for I had not the advantage of a galvanometer.

Mr. Clarke takes exception, and rightly, to the expression "burning through the cicatrix." That, I honestly confessed, was the false impression I started with. I began with crude ideas and rough instruments; through the liberality, however, of the Committee of St. Peter's Hospital and the kindness of Dr. Steavenson, these points have been rectified. I would cordially endorse what Mr. Clarke asserts about the strength and the effects of the currents; but I should not like to pass an opinion as yet upon the permanent efficacy of the treatment.—I remain, Sir, faithfully yours,

George-st., Hanover-sq., June, 1886. E. HURRY FENWICK.

LEICESTER AND ITS IMMUNITY FROM SMALL-POX.

To the Editor of THE LANCET.

SIR,—Omitting entirely the question of the value of the vaccination *cordon*, it seems to me that the isolation of small-pox cases pursued at Leicester is as much opposed to the anti-vaccination doctrine as is vaccination itself. A series of "Vaccination Tracts" by Dr. Garth Wilkinson and Mr. William Young, the secretary of the Anti-vaccination Society, has the following as the subject of Tract No. 12: "The imposture of the current small-pox lymph called vaccine, and the new imposture of calf-lymph. Also, the chaos of statute law, dealing with vaccine substance." The tract concludes by laying down seven "positions" which seem to form a kind of creed. The second "position" contains the following statement: "It [i.e., small-pox] is one of the least contagious of diseases ..... and its contagion is easily prevented by known means." The sixth "position" is: "Small-pox hospitals are the culminating mistake in the social treatment of the disease. They are sewers of death to their inmates. ..... The true policy with small-pox, *in itself* now an insignificant disease, is to let each case lie where it falls, and to treat it there as it ought to be treated." If, therefore, the immunity of Leicester from small-pox proves anything, it proves the value of what anti-vaccinators hold to be "the culminating mistake in the social treatment of the disease."

I am, Sir, yours truly,
JOHN C. M'VAIL, M.D.

Holmhead, Kilmarnock, N.B., June 16th, 1886.

BRITISH MEDICAL BENEVOLENT FUND JUBILEE.

To the Editor of THE LANCET.

SIR,—The following donations have been received or promised in connexion with this celebration:—

	£	s.		£	s.
Her Majesty the Queen (through Sir J. Paget) ...	100	0	Arthur Durham, Esq.....	21	0
Sir G. Burrows, President...	21	0	J. L. France, Esq.....	21	0

EDINBURGH.

(From our own Correspondent.)

ROYAL SOCIETY OF EDINBURGH.

At the fortnightly meeting of the Society held last Monday, amongst many valuable papers an important contribution to the study of the physiology of the blood was presented by Dr. William Hunter. Dr. Hunter has made a long series of experiments with a view to determining the usual duration of functional activity in the hæmocyte. To observe this with accuracy he made use of the method of transfusing the blood of one animal into the blood stream of another in which the microscopic character of the hæmocyte differed from that of the blood transfused. By this system of differential transfusion he has been led to the conclusion that the average life history of the red blood-corpuscle extends over a period of from two to three weeks.

POST-GRADUATE COURSES IN EDINBURGH.

A second meeting was held in connexion with this project in the hall of the Royal College of Physicians, on Tuesday the 22nd inst. Professor Sir Douglas Maclagan occupied the chair, and there were some thirty of the teachers in the Edinburgh School present. Considerable progress was made at this meeting towards a final settlement of the arrangements; the "clinical week" which was spoken of in the original proposal has been expanded to a course of three weeks' instruction. With the concurrence of the various boards of management, it has been arranged to throw open the various hospitals, dispensaries, and asylums, for the use of the practitioners who will attend, and courses of instruction will be carried on in each by teachers connected with the several institutions in question. After some discussion, it was decided that a fee of one guinea should be payable for a ticket giving admission to all or any of the courses of instruction. This fee is to be used in liquidating the expenses which will arise in connexion with carrying out satisfactory arrangements, and any surplus is to be divided proportionally between the public institutions in which the courses are held. The arrangements may thus be said to be already fairly under weigh, and there seems every prospect of the project having a complete realisation. During the last few days the suggestion has been largely canvassed amongst country practitioners, by whom it has been met with so warm an approbation that from their side at least the most cordial support is to be looked for. The meeting will occupy the last week in September and the first two weeks of October of the current year.

DR. WENDELL HOLMES.

Dr. Holmes has accepted an invitation from the Students' Representative Council to be present at a symposium to be held in the Oddfellows' Hall, Forest-road, on Friday night. It is expected that he will deliver a short address, and the evening will be enlivened by an enjoyable musical programme, carried out by the students themselves. In the afternoon of the same day Dr. Holmes is to receive the honorary degree of LL.D. Edin. at the hands of the Senatus and University officials at a private meeting in the Upper Library Hall.

Edinburgh, June 23rd.

IRELAND.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS: ANNUAL REPORT OF THE COUNCIL.

DURING the year ended April 5th last, eleven candidates were admitted to the Fellowship, ninety-one received the Letters Testimonial, six licentiates the diploma in Midwifery, and nine practising dentists the Dental diploma. The resolution of the College, that candidates should be classified at the examination for Letters Testimonial, was submitted to the Council at a special meeting, who confirmed the resolution, and arrangements have been made to carry it into effect. The conference with the College of Physicians in reference to a conjoint examination between the two Colleges came to an untimely end in October last, when the College of Physicians stated that they could not entertain the proposal as to the distribution of the surplus between the Colleges. I understand negotiations have recently been entered upon between the two Colleges for a conjoint examination; but the whole matter, in my opinion, depends upon whether the College of Physicians is willing to allow the Apothecaries' Hall to join the proposed scheme. If they do, all will, I believe, be amicably arranged; but if a refusal is insisted upon by the College of Physicians, the present conference will prove as abortive as its predecessors. The reason of this is, as stated in my last letter, that if the Apothecaries' Hall are prevented joining in the proposed scheme, they can

Digitized by Google

claim the right of obtaining examiners on application to the Medical Council, and so could issue licences in medicine, surgery, and midwifery for very small fees; which arrangement the College of Surgeons, for obvious reasons, very properly object to. Certain changes have been adopted by the Council in reference to the answering of candidates at examinations, and candidates, in order to pass, must attain at each examination a certain standard mark in each subject. For example—in anatomy and surgery, 50 per cent. for each; physics, chemistry, and materia medica, 35 per cent. for each; medicine, histology, physiology, midwifery, and ophthalmology, 40 per cent. for each; botany, pharmacy, and medical jurisprudence, 25 per cent. In accordance with representations made by the President, Sir Charles Cameron, to the Commissioners of Valuation, a revaluation of the College premises took place, which resulted in the remission in future of a considerable portion of the very heavy taxation to which the College had heretofore been subjected. Other matters in the report have to a great extent been already referred to in these columns, and it is unnecessary to reproduce them.

LOCAL GOVERNMENT BOARD.

The annual report has been issued rather earlier this year than usual, and from it I find that the returns for the past year show a decline in the average daily number of persons relieved in the workhouses. There was, however, an increase in the average daily number of persons afforded relief out of the workhouses, the increase amounting to 1136 persons. These returns refer to October of last year; but since January last there has been considerable distress among the poorer classes, and the outdoor lists are in excess of the previous year by 6854. There has been a decrease of 867 in the total number of sick admitted to workhouses, and an increase of 22,218 in the number admitted who were not sick, thus showing an increase of 21,351 in the total number admitted during the year. The number suffering from fever or other contagious disease was less by 1151. The total number of deaths in the workhouses was 10,925, or a decrease of 313. Of these, deaths by fever were 371, as against 510; by lung disease, 1997, as against 1929; and deaths by small-pox, 2, as against 1 in the previous year. There were 17 cases of small-pox treated by dispensary medical officers during the year, being the lowest number recorded during the past 22 years. The total expenditure of poor-rates for poor relief, medical relief, sanitary measures, superannuation, &c., was £1,258,465, being a decrease of £28,270 as compared with the previous year.

Dublin, June 15th.

PARIS.

(From our own Correspondent.)

ELECTION OF DR. BROWN-SÉQUARD TO THE ACADEMY OF SCIENCES.

THE portals of the Paris Academy of Sciences have at last been opened to Dr. Brown-Séquard, as he was elected member at its last meeting on Monday, in the Section of Medicine and Surgery. The eminent biologist was elected by a large majority, and the victory was the more creditable as the competitors of Dr. Brown-Séquard were all men of note, in proof of which statement I have only to mention the names of Germain-Sée, Bouchard, Jaccoud, Hayem, and Richet.

REVACCINATION.

In a work lately published by Dr. Jules Besnier, entitled "Revaccination of Young Subjects, and particularly of Collegians, compared with that of Adults," the author, from his own experience at the College Rollin, of which he is physician, arrives at the following conclusions:—1. The success obtained by the revaccination of subjects revaccinated for the first time increases rapidly with age, notably in collegians, and attains its maximum from fifteen to twenty years of age—that is to say, in adolescence. In adult age, the success is less than in adolescents, and it increases with years, only very slowly and in a manner scarcely preceptible. 2. The elevation of the figure of successes, in adolescence, depends, on the one hand, on the age of the subjects—that is to say, the time that elapsed since vaccination; and on the other, on the divers conditions of soil or constitution, such as the period of growth, college life, regimen, &c. 3. Certain maladies favour the vaccinal receptivity at the different periods of life, and thus contribute to increase the number of successes; while others, on the contrary, would have no influence of this kind. Among the former are certain acute maladies, which have a profound influence on the economy, and notably typhoid fever; among the latter would be the ordinary eruptive fevers in young subjects, and chronic maladies in adults. 4. In subjects vaccinated at birth and not revaccinated, the variolic receptivity, like the vaccinal, attains its maximum in adolescents—that is to say, from fifteen to twenty years of age, and diminishes, on the contrary, in adults. 5. These are so many reasons which justify revaccination in young subjects, and in particular collegians. For the latter, the vaccine from the cow is preferable to the vaccine from the child, and, in the absence of an epidemic of small-pox, the time most opportune to practise this revaccination is that of the month of March or April, which would be after the Easter holidays.

INSANITARY CONDITION OF PARIS.

The Parisian authorities, and, indeed, the citizens themselves, are reminded of the insanitary condition of their great metropolis by the offensive odours which are almost permanently prevalent in it. These become more intolerable during the hot weather, and no wonder, when it is considered that this city contains no less than 80,000 cesspools, with a population of over 2,000,000. The Council of Hygiene and the Academy of Medicine of Paris have been frequently appealed to for suggestions as to how this nuisance may be removed. As usual, the members of these learned bodies are divided as to the real cause of the nuisance, some attributing it to the fermentation of the dejections stored up in the cesspools, while others ascribe them to the sewage farms which are established outside the city. Among the remedies proposed may be mentioned the abolition of the cesspools, the removal of the effete material at short intervals, or the emptying of it into the sewers, which in their turn are to be emptied into the Seine near its mouth. The latter idea was borrowed from the English, but the adversaries "tout à l'égout" remind the partisans of the English system of the bad smells lately complained of in the House of Commons, which were evidently due to defective sewerage. M. Pasteur was even consulted on the subject, and the adversaries to emptying all the refuse matter of this city into sewers laid the following proposition before the illustrious *savant* in the following terms:—"Here is a malady [charbon] which is characterised by germs which may persist; if this be the case with the germs of all contagious maladies (diphtheria, scarlatina, typhoid fever), it is certain that 'tout à l'égout' will constitute a great danger." To this M. Pasteur replied: "In fact, I must acknowledge that science is not complete on all these maladies. It is for charbon, but it is not yet for small-pox, diphtheria, scarlatina, nor for others. Their germs are not known; we do not know whether these maladies have germs." In reply to a question by a member of the Council of Hygiene, M. Pasteur stated the difference which exists between scientific solutions which are slow to be effected and practical solutions exacted by imperious circumstances. "The question to be determined, put before science as it is, cannot be solved at present. Science on this point is altogether incomplete. Put before engineers, it is a different thing. Often engineers and public men are held to solve certain questions, even when science is not completed on these questions. A man of the laboratory, I can only count with established principles. You engineers ought to arrive at practical solutions even in the presence of a science unachieved."

THE CHARGES AGAINST PROFESSOR CHATIN.

The Commission ordered by the Minister of Public Instruction, and composed of MM. Berthelot, Member of the Academy of Sciences, Béclard, Dean of the Faculty of Paris, and Greard, Dean of the University of France, to investigate the charges brought against Professor Chatin by the students of the School of Pharmacy, has exonerated him, as nothing was found to impeach his honour or to justify the complaints of the students. The ringleaders of the disturbances created at the School of Pharmacy, and which have been reported in THE LANCET, have been punished. Two of them were sent before the Correctional Police, by whom they were condemned to six and four days' imprisonment, and to a fine of 50 francs respectively.

EGYPT.

(From our own Correspondent.)

EXAMINATIONS AT THE MEDICAL SCHOOLS.

THE annual examinations at the Medical School have just taken place, and were honoured on the closing day by the presence of His Highness the Khedive, the two High Commissioners, and all the native Ministers. The examiners consisted of seven Europeans and seven natives, besides the twelve native professors of the school, all being under the presidency of Dr. Salem Pacha. The examination is entirely *viva voce*, but it is hoped that the system of writing papers on the most important questions will be introduced next year. In the first class, consisting of those who had completed five years' medical study, were nineteen youths, and of these only one was referred to his studies. The eighteen will now undergo a competitive examination at Kasr-el-Aini Hospital in practical subjects; the first six will be elected as house-surgeons there for a year, and will receive £72 and lodging, while the others will work for the same period without pay as dressers and clinical clerks. At the end of the year they will pass another examination, receive certificates to practise, and start fairly in the Government service. The six youths who are now emerging from their hospital work are much smarter and more useful than their predecessors, who under the old system never received any practical training, and they will now be temporarily attached to the Sanitary Department, to take the place of the hospital surgeons in the provinces, each of whom in turn is to come up to Cairo and work for three months at the central hospital here.

KASR-EL-AINI HOSPITAL.

Dr. Milton has just completed his second year of residence at this hospital. During the first year there were many cases of erysipelas and septicæmia; but during the second there has not been a single case of blood-poisoning in the surgical wards, though the average number of in-patients has been raised from 300 to 550, and the number of surgical operations has been largely increased. This salutary change is probably due to the care bestowed upon ventilation, cleanliness of patients, irrigation of wounds, and in the closing of a most obnoxious system of foul latrines and a network of cesspool catacombs opening into the Nile.

THE MILITARY HOSPITALS AT CAIRO AND ALEXANDRIA.

The English military hospitals in Cairo and Alexandria are unusually full of sick, most of the patients having come down from Upper Egypt. At Assouan there is at least one death daily, and sometimes more, among the four regiments now stationed there. The soldiers are young, they have no work and practically no amusement, and are struck down in numbers by enteric fever. The heat varies from a minimum of 100° just now to 116° in the tents, and has caused a few cases of sunstroke. Recently eight drummer-boys were sent out from England to a regiment stationed at Korosko, of whom three died, four were invalided, and the eighth was left behind when the regiment evacuated Korosko, only to die the following day.

NEW WATER-SUPPLY AT ROSETTA.

The ancient town of Rosetta, although situated on one of mouths of the Nile, has hitherto suffered from a complete dearth of fresh water at the time of low Nile, owing to the river being at that time slightly below sea-level. This town is notorious for the number of cases of elephantiasis, as well as other diseases, and Dr. Sandwith was fortunate enough to enlist the powerful aid of Colonel Scott Moncrieff in his endeavours, two years ago, to improve the water-supply. A fresh water canal of twenty-four miles from Atfeh to Rosetta has now been completed, and a daily supply of 650,000 gallons for the latter is established, besides the irrigation of some thousands of acres of waste land through which the canal passes—to the great delight of the neighbouring fellaheen. A dam 730 yards in length, further up the river, will also prevent the supply of drinking-water for Alexandria and the towns and villages along the Rosetta branch of the Nile and the Mahmoodeeyeh canal from being tainted by the inroad of sea-water, as has occasionally happened during former years.

TOURAH CONVICT PRISON.

An epidemic of relapsing and typhus fevers has broken out at the Tourah Convict Prison near Cairo, but it has been well combated by the Sanitary Department, and no cases have spread to the neighbouring villages, though many of the prison officials have contracted relapsing fever.

CAIRO LUNATIC ASYLUM.

This asylum, under the direction of a native doctor, sustains its reputation for cleanliness and usefulness. It now contains 250 men and sixty-two women. Three-fourths of the men are suffering from the effects of hasheesh (cannabis indica), besides about ten cases due to alcoholism. Nymphomania accounts for many cases among the younger women. A very successful garden has now been made, and mat-making and carpentry are carried on daily by the inmates. Quite lately a donkey boy was admitted as a patient, was taught mat-making, and now, cured of his insanity, he has adopted it as his trade in Cairo. At my last visit to the asylum I was accompanied by the resident physician to a large Scotch pauper asylum, who said that all the arrangements here compared favourably with those to which he was accustomed in Scotland. But much remains to be done, especially in the direction of making the lunatics do out-door work. I noticed fifteen criminal lunatics in the wards, one of whom was a notorious ferryman from Mansourah, who used to murder his passengers and throw their bodies into the fast-flowing Nile.

THE SANITARY DEPARTMENT.

One of the most recent additions to the Sanitary Department is a young sanitary engineer, with a varied experience of seven years in England. He has already been employed by one of the chief native house-builders, who wishes to alter a house recently completed, and also to build a new one on approved sanitary principles, by which means he hopes to ensure for himself a succession of English tenants.

Cairo, June 1st.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an extraordinary meeting of the Council held on Thursday last, on the confirmation of the minutes of last meeting, the following resolution, slightly amended, was adopted in the case of Mr. Bryceson:—"That Mr. Bryceson be allowed to present himself for the final examination for the Diploma of Member on producing certificates of having attended anew at the London Hospital College of Medicine the several courses of lectures which were invalid in his Schedule—viz., the courses on Materia Medica, Midwifery, Chemistry, Practical Chemistry, Medicine, and Pathological Anatomy."

Mr. Alabone, a Member of the College, attended at the summons of the Council to answer questions in reference to certain notices of him which had appeared in various public journals, and, having made a verbal statement, was called upon to make a statement in writing for the further consideration of the Council.

MEDICAL NOTES IN PARLIAMENT.

Medical Acts Amendment Bill.

IN the House of Lords, on the 18th inst., Earl Spencer moved the second reading of the Medical Acts Amendment Bill, and briefly alluded to the necessity of legislation on this subject, and reviewed the main provisions of the Bill. The Duke of Richmond and Gordon said that he believed the provisions of the Bill had been carefully considered in the other House, and agreed in the opinion that it had been very skilfully managed by the Vice-President. He gave notice that he would move amendments in Committee which would have the effect of making the Universities of Aberdeen and St. Andrews each elect a member to the Council. The Duke of Argyll said he should support the proposition of his noble friend. It was the only case in the Bill in which two universities were tied together to make one appointment. As the Bill now stood, the Irish Universities would each appoint one member, making five in all, whereas in Scotland they would only have three members. After a few words from the Earl of Milltown, Earl Spencer said he would discuss the subject in Committee, but he was afraid there

Digitized by Google

would be some considerable difficulty in re-arranging the matter. The Bill was then read a second time.

On the 21st the House went into Committee on the Bill, and the Duke of Richmond moved an amendment, giving the Universities of Aberdeen and St. Andrews separate representation on the Council to be formed under the Bill. The amendment was opposed by Earl Spencer, but on a division was carried by forty-four votes to forty-one. The Bill passed through Committee.

On the 22nd report of amendments to the Bill was received, and on the 23rd it was read a third time and passed.

The Contagious Diseases (Animals) Bill.

On the 21st inst. the Commons' amendments to this Bill were agreed to.

The Idiots Bill.

In the House of Commons, on the 18th inst., the Idiots Bill passed through Committee, was reported without amendments, and read a third time.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone all the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board of Examiners on the 17th inst.:—

Barstow, Charles Albert, James-street, Harrogate.
Jones, Alfred Ernest, Stamford-hill.
Mansbridge, Josiah, West Hampstead.
Milot, Charles Frederick, Grange-park, Ealing.
Whittaker, George Oldham, Blackley, Manchester.
Wright, Charles Frederick, Edgware-road.
Wrighton, Thomas Henry Garland, Buckhurst-hill.

(Candidates referred, 7.)

The library of the College will be closed on Wednesday, June 30th, for the purposes of the examinations; on Thursday, July 1st, for the Council election, and on Friday, July 2nd, for the examinations.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 18th inst., the degree of M.B. was conferred on

Keightley, Archibald, Pembroke. | Robb, Charles Edward, Caius.

ROYAL COLLEGE OF PHYSICIANS IN IRELAND.—At the June examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Edward Corcoran, James Corcoran, Thomas Crowe, Robert Vicars Fletcher, Edward Jonathan Goode, George E. Hughes, Richard Mandeville Hugo, Joseph Peter Kelly, John Fredk. Kennedy, Timothy Robert Killeen, John Edward Langan, Reginald Thomas Alexander Levinge, Charles Madders, William J. Peacocke, James Albert Frederick Sawyer, Arthur Ernest Switzer, William Joseph Taylor, Thomas Wilford Twinem, Thomas Verner.

MIDWIFERY.—Edward Corcoran, James Corcoran, Benjamin Devonsher Dickson, Edward Jonathan Goode, George E. Hughes, Richard Mandeville Hugo, John Frederick Kennedy, Reginald Thomas Alexander Levinge, Alfred Edward Thomson, Francis Edward Townsend, Thomas Verner.

Last month the undermentioned was admitted a Member:—

Myles Joseph Jordan.

SOCIETY OF APOTHECARIES.—The following gentlemen passed their examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 17th inst.:—

Birch, Charles Ormond, Harley-street.
Denman, Robert, Sydenham.
Freeman, Richard Austin, Caledonian-road.
Morris, Edward, Wharton-road, West Kensington-park.
Williams-Freeman, John Peere, Bursledon, Southampton.
Yolland, John Horatio, Hoylake, Birkenhead.

THE sum of 800,000 francs has been contributed from national and municipal sources for the erection of anatomical and chemical institutes in Nancy.

DENTAL HOSPITAL OF LONDON.—His Grace the Archbishop of Canterbury has accepted the office of a Vice-President of the above hospital.

THE CONDITION OF THE RIVER LEA.—The Select Committee appointed to inquire into and report upon this subject have reported upon the evidence they have had before them, and recommend that a committee be appointed on the assembling of next Parliament to consider their report, and, if desirable, to take further evidence. The committee trust that the Lea Conservancy Board will duly exercise their rights regarding the quantity of water they are entitled to pass through their locks in priority to either of the two water companies during the dry season of the coming summer.

NORTH LONDON CONSUMPTION HOSPITAL.—Sir Henry Holland presided at the annual festival of this charity, held on Wednesday, at Langham's Hotel. The contributions announced during the evening amounted to £1256.

THE AMERICAN EXHIBITION IN LONDON.—President Cleveland has accepted the honorary presidency of the American Exhibition to be held in London in 1887, and will perform the opening ceremony by telegraph from the White House.

A PRIVATE FEMALE UNIVERSITY is to be established in Moscow through the efforts of Mdme. Fischer, who has now a girls' gymnasium there. The university is to have three faculties—Philological, Mathematical, and Scientific. The last will probably ultimately be expanded into a medical faculty.

GUY'S HOSPITAL.—The annual distribution of prizes to successful students of the hospital will take place at 3.30 P.M. on Friday, July 2nd, in the grounds of the institution. The wards and museums will be open to visitors from 4 to 5 P.M., and ladies are invited to be present.

THE PASTEUR INOCULATION IN RUSSIA.—The Odessa correspondent of the *Daily News* telegraphs: "From the 24th inst., all persons in Russia bitten by rabid dogs and wolves will be treated in this city by Dr. Gamelei, for whose initiatory operations lymph has been supplied from M. Pasteur's laboratory."

PRESENTATIONS.—An address and two cases of surgical instruments have been presented to Mr. J. Shaw, M.B., C.M., by the members of the classes of the Sheerness centre of the St. John Ambulance Association, as a testimony of their appreciation of his services to the Association during the several courses of lectures and practical instruction which he has given.—A large and handsomely chased salver has been presented to Mr. David Davies, M.R.C.S., L.S.A., late medical officer of health to the Urban Sanitary Authority for the city and county of Bristol, by the local magistrates, members of the Town Council, and persons officially connected with him.

RABIES AND HYDROPHOBIA.—Sir Charles Warren, the Chief Commissioner of Police, has just issued some statistics with regard to mad dogs and deaths from hydrophobia which have come under the notice of the Metropolitan Police from January, 1885, to May, 1886. During this period the total number of mad dogs was 495. The lowest number was in January, 1885, when there were only 8. From this date the number of cases varied for each month as follows: February, 10; March, 22; April, 20; May, 34; June, 38; July, 47; August, 28; September, 31; October, 31; November, 58; December, 46; January, 1886, 27; February, 14; March and April, 29; and May, 23. The deaths from hydrophobia, which are taken from the Registrar-General's returns, numbered 26 up to December, 1885, the greatest number being in October and November, when there were 5 in each month. Between January and May, 1886, there were 7 deaths.

THE HAMILTON ASSOCIATION.—The annual meeting of this Association, for providing trained male nurses, was held on the 23rd inst., Sir Thomas Crawford, K.C.B., M.D., Director-General of the Army Medical Department, presiding. The report showed that great progress had been made during the year which had elapsed. A considerable number of male nurses had been employed under the Association, and in nearly every case those engaged had given satisfaction. The chairman said that the need of such an Association had been long known to him, and most keenly was it felt in the army. This Association seemed admirably adapted to meet the want long felt by the sick in cases in which male nurses would be preferred. He closed by moving the adoption of the report. Sir Joseph Fayrer seconded the motion, and said that nothing had delighted him more after a long absence from this country than to find on his arrival the admirable system of lady nursing which had been established, and which so greatly simplified the treatment of disease. Still, there were patients who, on account of the nature of their complaint, objected to be under the care of female nurses, and the want of male nurses this Association was admirably adapted to supply. The meeting was afterwards addressed by C. R. Van Lennep, Dr. Prosser James, Mr. Archibald C. Sim, Dr. Don, Mr. Smith (auditor), and Sir J. Danvers.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BENNETT, FREDERICK WILLIAM, M.D. Lond., M.R.C.S., has been appointed Honorary Assistant Physician to the Leicester Infirmary and Fever House.

BULLEID, E. G., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Seventh District of the Hexham Union.

CHILD, HERBERT, M.R.C.S., L.S.A., has been appointed Medical Officer for the Fourth District of the North Bierley Union.

CLARK, FRANK W., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Croydon Infirmary, vice G. A. S. Gordon, L.R.C.P.Ed., L.R.C.S.Ed., resigned.

GIBB, WILLIAM, M.B., C.M., has been appointed Medical Officer of Health for the Burgh of Millport, Isle of Cumbrae.

HUTCHINSON, PROCTER S., M.R.C.S., has been appointed Resident Medical Officer to the Hospital for Diseases of the Throat, Golden-square.

MAHOMED, A. G. S., M.R.C.S., L.S.A., has been appointed Medical Officer for the Third District of the Christchurch Union.

MORLEY, THOMAS S., M.D.Lond., M.R.C.S., has been appointed Medical Officer for the Barton District of the Glandford Brigg Union.

MYLES, THOMAS, M.B., B.Ch.Dub., F.R.C.S.I., has been appointed Surgeon to the Jervis-street Hospital, Dublin, vice Chance, resigned.

NEALE, J. HEADLEY, M.B., C.M.Edin., M.R.C.P.Lond., has been appointed Honorary Assistant Physician to the Leicester Infirmary and Fever House.

RICHARDS, ROBERT C., M.R.C.S., has been appointed Medical Officer for the Third District of the Hexham Union.

ROUGHTON, B. WILKINSON, M.D.Lond., M.R.C.S., has been appointed Assistant Demonstrator of Anatomy to St. Bartholomew's Hospital.

SMITH, HORACE, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Parkham District of the Bideford Union.

Births, Marriages, and Deaths.

BIRTHS.

DRYSDALE.—On the 14th inst., at Château d'Oex, Switzerland, the wife of Alfred Drysdale, M.B.Lond., L.R.C.P., of Cannes, of a son.

DUNDAS.—On the 15th inst., at Fakenham, Norfolk, the wife of Mordaunt G. Dundas, M.R.C.S., L.S.A. of a daughter.

HOOKER.—On the 16th inst., at Gosport, the wife of Charles Hooker, L.R.C.S., L.R.C.P.Ed., of Cirencester, of a son.

JONES.—On the 22nd inst., at 6, Westbourne-street, Hyde-park-gardens, the wife of T. W. Carmalt Jones, M.A., F.R.C.S.Ed., of a son.

MARRIAGES.

BIGGER—WHITTARD.—On the 16th inst., at St. Matthew's Church, Brixton, William Grimshaw Bigger, M.B., M.R.C.S., to Emily Philadelphia, second daughter of John A. Whittard, of Rydal Mount, Streatham-hill.

DAVIES—DIXON.—On the 16th inst., at Holy Trinity Church, Stroud-green, N., William Thomas Frederick Davies, M.B., B.S.Lond., of Swansea, to Florence, daughter of Thomas Dixon, Esq., of Stroud-green, and Dutoits Pan, South Africa.

DOWSON—MORGAN.—On the 17th inst., at St. George's, Brandon-hill, Bristol, Walter Dowson, M.A., M.B.Cantab., of Great George street, Bristol, to Blanche, second daughter of George King Morgan, of Cherith Lodge, Clifton.

MACDONNELL—HOLMES.—On the 17th inst., at St. Michael's, Stoke, Henry MacDonnell, Fleet Surgeon, R.N., Royal Marine Depôt, Walmer, to Frances Alice, eldest daughter of the late Sir William Holmes, of Manor House, Kilrea, Ireland.

NANKIVELL—HULL.—On the 10th inst., at Holy Trinity, Bournemouth, Herbert Nankivell, M.D., of Pen-Mellyn, Bournemouth, to Constance Alice, fifth daughter of the late William Winstanley Hull, of The Knowle, Hazelwood, near Derby.

ROE—ROE.—On the 16th inst., at St. Mark's, Kennington, Francis Christian Roe, L.R.C.S.I., L.K.Q.C.P.I., &c., to Carrie, second daughter of Robert Roe, of Clifton House, Kennington-park-road.

WOOD—MADGEN.—On the 23rd inst., at St. Hilda's, South Shields, by the Rev. James McGrigor, John Cundell Wood, L.R.C.S., L.R.C.P.Ed., son of Peter Wood, of Sunderland, to Ellen Maude Madgen, second daughter of the late W. A. Madgen, of Greencroft, Haltwhistle.

DEATHS.

BENTHALL.—On the 14th inst., at Sherborne, Dorset, Alfred Elliott Benthall, F.R.C.P.Ed., fourth son of Edward Benthall, late Bengal Civil Service.

DIAMOND.—On the 21st inst., at Twickenham House, Middlesex (after a long illness), Hugh Welch Diamond, M.D., F.S.A.

GIRDLESTONE.—On the 14th inst., at Château Falaise, Biarritz (after a few days' illness), Charles Girdlestone, M.D., son of the late Rev. Harry Girdlestone, of Landford Rectory, near Salisbury, aged 64.

MURDOCH.—On the 20th inst., at Malta, Alexander Brown Murdoch, M.B., C.M., Surgeon, H.M.S. *Superb*, aged 26 years.

PARR.—On the 19th inst., at Ravenleigh, Betchworth, Surrey, Alfred Parr, M.D., aged 66.

RINGROSE.—On the 22nd inst., at Woodgreen, Basil Ringrose, M.R.C.S., in his 47th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

Letters requiring notice must be authenticated by the name and address of the writer.

We cannot undertake to return MSS. not used.

THE APOTHECARIES' SOCIETY AND THE MEDICAL BILL.

L. S. A.—The Medical Bill will require the Apothecaries' Society either to combine with other Corporations, or to get assistant examiners from the Medical Council. In one of these ways it is intended to secure that the diploma shall be a registrable qualification in medicine, surgery, and midwifery.

B. S. (Huddersfield).—According to Dr. Salvatore de Renzis, in the Preface to his great edition of Celsus (two vols. 4to, Naples, 1851), the University of Edinburgh about the year 1770 was in treaty with Lupacchini to purchase the MS. of the edition of the Latin writer's "De Arte Medicinæ," on which he had long been engaged; but Lupacchini declined to come to terms. Not long afterwards he died of hydrophobia; but his valuable critical labours were not allowed to perish, having been incorporated in Targa's edition (Verona, 1810), and more recently in that of De Renzis's himself.

Aristarchus is referred to a general notice at the head of this column.

APPLICATION OF FORCEPS.

To the Editor of THE LANCET.

SIR,—From time to time one reads in the medical periodicals of the difficulty felt in introducing the upper blade of midwifery forceps, from the handle coming in contact with the bed. I also experienced this difficulty until I read in a contemporary an article written by a general practitioner whose ingenuity seemed only equalled by his common sense. He advised simply that the upper blade be introduced first as the lower and gently rotated into its final position, when the lower can be as easily introduced as if the other blade were not in position, provided the upper handle be kept well aside. I always now employ this method, and have experienced no difficulty since, and I here tender my thanks to the ingenious man who gave me such a practical "tip." This disposes of all complications, such as hinged upper blade handles, having the hips well over the edge of the bed, &c. Why the upper blade should be recommended to be passed last has always been a mystery to me, but so I have been taught and have read in text-books, and here I wish to enter my protest against such a difficult and unnecessary proceeding.

Where the excellent continental method of introducing the forceps can be employed, the patient being on her back, both blades are easily passed, the upper and lower becoming right and left lateral.

I am, Sir, yours faithfully,

Driffield, June 17th, 1886. A. T. BRAND, M.D

THE CHOICE OF A MEDICAL ATTENDANT.

Z.—We do not profess to answer correspondents who are not members of the profession on questions of medical ethics, or to insert their communications. Anyone has an undoubted right to choose or to change his or her medical attendant, but this should not be done capriciously or unreasonably.

Ethics.—A seems to have been treated with scant justice and courtesy: so much so that we almost think B must have omitted—unintentionally, of course—some point in the case. To commence practice as a matter of retaliation would be a severe measure, but the provocation is certainly considerable. B should at least have paid all A's expenses after inducing him to go so far; and perhaps might be made to do so.

Mr. Snell.—Very soon.

SHIP SURGEONS.

To the Editor of THE LANCET.

SIR,—Will you allow space for a few words with reference to the present position of the medical service of Atlantic steamships. A ship's surgeon ranks below, and his name on the passenger list comes after, the purser—he who looks after the ship's accounts is reckoned of greater importance than he who looks after its health: I was assured a short time since by an officer that in a well-known Atlantic company the doctor was not allowed on the quarter-deck after the first day or two, when the ladies were supposed to have got over sea-sickness. Once, having to complain of the insanitary condition of a ship, before sending in my report I showed it to the captain, who, during its reading, ejaculated "You'll get yourself disliked, they'll take no notice of *you*, and it's no business of yours." The letter, however, was sent, and, I am glad to say, acted upon; but it might have been at the cost of my dismissal from the service. On the voyage out to New York every unvaccinated steerage passenger, unless protected (i.e., has had small-pox), must be vaccinated before he can land at Castle Garden. This means examining it may be 1000 people—not long ago I examined nearly 900,—and they are not always free from pediculi, or even clean. A fair fee should be allowed for each successful vaccination; and this would also be a sufficient safeguard against all slipshod inspections. In most ships the purser has the seating of the passengers at table; the tagrag and bobtail are generally, as a matter of course, placed at the doctor's end.

I am, Sir, your obedient servant,

London, June 15th, 1886. M. A. P.

"INFANTICIDE BY PERAMBULATORS."

A CORRESPONDENT writes from Belfast to enforce the suggestion, made last week in our columns, that children carried in perambulators should sit or lie with their faces towards the nurse.

G. N.—The question is discussed in another column of our present number.

Mr. J. T. Williams.—In an early number.

PRACTICE IN CANADA.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "Colonist," whose letter appeared in your issue of May 29th, I may say that most of the appointments here—as to gaols, penitentiaries, lunatic asylums, &c.—are political in character, and are only obtained through Government influence. Hospital appointments yield little but experience. In the General Hospital here the medical superintendent receives £250, with rooms, &c., but the three house-surgeons receive nothing but their rooms and board. In the provinces of Ontario and Quebec a licence must be obtained from the College of Physicians and Surgeons of the province. In the other provinces a licence is granted by the respective provincial Governments. The fees are for the most part small, ranging from £1 to £6 in the different provinces. The profession in Canada is quite full enough. I have supposed that "Colonist" is a licentiate of one of the Royal Colleges; otherwise he will have an examination (in Ontario and Quebec) equal to theirs to pass, and the fees are consequently larger.

I am, Sir, yours faithfully,

Montreal, June 10th, 1886. L.C.P.S. QUE.

A Country Practitioner.—See Manual of Surgery, edited by Treves, vol. ii., p. 509; Holmes' System of Surgery, vol. ii., p. 636; Pye's Surgical Handicraft, p. 49. The instrument is made by Messrs. Arnold and Sons.

Mr. C. S. Jeaffreson.—Yes.

Mak is referred to the Medical Directory, published by Churchills.

"IODOFORM SPRAY."

To the Editor of THE LANCET.

SIR,—Would Mr. Alfred Leach, who wrote under the above heading in your issue of June 12th, p. 1148, have the goodness to give your readers a more detailed method of producing a *solution* of iodoform for spray. His prescription is rather lax. How are the terebene and iodoform made into a homogeneous solution? I have only succeeded in suspending the latter (which soon blocks the fine tube of the spray-producer), and the former floats on the top of the mixture. I think a *solution* of iodoform without ether would be a preferable application in many cases of inflamed or relaxed mucous membrane.—I am, Sir, yours truly.

June 23rd, 1886. INQUIRENS.

AN AVERTED SCARE.

LAST week Florence and its neighbouring townships were thrown into something very like panic by the announcement that three persons had died in the Via Pellicceria after a few hours' suffering from Asiatic cholera. The alarm was rapidly developing into a scare, and preparations for a stampede on the part of all who could get away were becoming general. But the Tuscan nature is less superstitious and impressionable than the Neapolitan, and there was still time for an appeal to the common-sense and the self-control of the Florentines. That fortunate interval was promptly utilised by the municipality. Medical authority of the highest kind was at once brought to bear on the seat of the supposed outbreak, and in a few hours the fatal cases were proved and published to have been due to violent gastro-enteritis caused by the drinking of contaminated water. The announcement was a calmative of the most effective kind; the city and suburbs resumed their wonted joyous animation; and now day has succeeded day without the slightest symptom among the inhabitants either of cholera or of its consequent scare.

Dr. C. F. Hutchinson.—The letter is very bad, but it is not worth notice.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—May I beg space in your valuable journal to ask assistance for a most deserving case which calls for immediate help. It is that of the widow of a medical man who died a few years back without making any provision for his wife and four little children. She has used her utmost endeavours up to the present time, and worked very hard to provide for the welfare of her family, who are all dependent upon her for support. She is now very much out of health from continued anxiety and the many privations she has had to endure, and for the present is unable to pursue her previous occupations; in fact, is reduced to selling the few things she has gathered together for present maintenance. I propose therefore, through your kind assistance, to start a fund, which will, I hope, relieve her present distress, and afford the means for her embarking upon suitable and remunerative employment as soon as she is able. I trust that all readers of your journal will respond to my appeal by sending whatever small donation may be agreeable to them. These with larger amounts will be thankfully received and acknowledged by myself. I may add, that if any subscriber to the fund desires a more detailed account of the case I shall be pleased to give any further information that may be wished. Sir Andrew Clark has already subscribed, and Sir James Paget has promised to do so when a fund is started.

I am, Sir, yours, obediently,

R. FITZROY BENHAM.

Abercorn House, Baron's Court, June 15th, 1886.

R. Bonstead.—Twenty-three grains and a half of cocaine have been taken by an adult without fatal effects. We cannot, therefore, assume that it is dangerous to use a small quantity superficially or hypodermically on a child a month old. We should not, however, recommend its use with a view to the removal of "a rather superficial nævus;" for it would be practically inert applied to the surface of the nævus, and to inject it into its substance would be almost as painful as the operation chosen to destroy the growth. We have known it injected beneath the skin and mucous membranes in the adult in sufficient quantity to efficiently remove sensibility, and yet not cause toxic symptoms. In an adult it is not so much the actual pain of a minor operation which the surgeon has to consider as the mental and emotional state of the patient incidental to an operation. In a child a month old the personal equation is a much simpler one; so that at that age it is seldom advisable to administer a general or local anæsthetic for the cure of a nævus.

Mr. Holford (Jersey).—We regret there is no law to prevent it.

REMARKABLE CASE OF DEFORMITY.

To the Editor of THE LANCET.

SIR,—A child with the following congenital defects has been admitted into the Tottenham Hospital, under Dr. Lichtenberg:—Absence of globes of both eyes (palpebral fissures present); hare-lip, with slight anterior fissure in palate; slight talipes equino varus. Both fontanelles are open, and joined by separation of parietal bones. There is a flattening of one side of the head, with corresponding bulging of opposite side. The body of the child (a girl) is well nourished. There is no apparent cause; three older children are all healthy; no consanguinity between parents, but consumption in both their families; the mother received a fright while driving during the eighth month.—I am, Sir, yours truly,

LLOYD G. SMITH, M.B.

Training Hospital, Tottenham, June 21st, 1886.

ERRATA.—In Mr. Hartzhorne's letter, published in our issue of the 12th inst., p. 1148, speaking of the properties of cocaine, vaseline, and glycerine, vaseline should have been quoted as forming *seventy-four*, instead of "twenty-four" parts of the whole.—In our notice last week, page 1180, of the use of Indian hemp in dental operations, the name "Aarousin" should have been printed *Aarönson*.

Holloway Press, Advocate of India, Northern Echo, Govan Press, North Star, Cape Argus, European Mail, &c., have been received.

Medical Diary for the ensuing Week.

Monday, June 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, June 29.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Wednesday, June 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; and on Friday, 2 P.M.; and Saturday, 1 P.M.

Thursday, July 1.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, July 2.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Annual General Meeting. Dr. M. J. Symons (Adelaide): Double Symmetrical Corneal Changes.—Mr. W. A. Brailey and Mr. Simeon Snell: Nævus of Choroid with Secondary Glaucoma.—Mr. E. Nettleship: Case of Transverse Calcareous Film of Cornea after Operation.—Mr. W. A. Brailey: Case of Double Glaucoma (Microscopical Specimens).—Mr. W. J. Cant: Paralysis of both Sixth Nerves, with Morbus Brightii.—Mr. W. A. Brailey: (1) Tubercular Iritis; (2) Interstitial Keratitis (? tubercular).

Saturday, July 3.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3
To CHINA AND INDIA ..... One Year 1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

"THE LANCET"
SECOND SPECIAL SUPPLEMENT,
IN SUPPORT OF THE
METROPOLITAN HOSPITAL SUNDAY FUND.

MEDICINE, THE CHURCH, AND THE PEOPLE.

MEDICINE and the Church have been closely connected from the earliest times. There was a period, long anterior to the Middle Ages, when the healing art and religion were still more closely connected than ever before, and that was when the great Founder of Christianity himself was upon the earth. Christ was a teacher and preacher to the people, and he was also a healer of the sick. In the crude development of religion and the curative art, the offices of priest and physician were found associated in the same individual. The medicine man was the priest, and the wise man who cured the evil spirit was the doctor. Society follows the general law of the development of organisms—viz., the growth of special organs for special functions. We therefore find in higher civilizations doctors of disease distinct from priests, and in the highest and most complete civilization of all the priest making use of the doctor of medicine to help him do his work of charity. The hospital is the outcome of this development.

In London to-day, through the instrumentality of the Hospital Sunday Fund, every minister of religion who makes a collection for the hospitals on Hospital Sunday is enabled, quite apart from the amount collected and to the full extent of the requirements of the poorest of poor parishes and congregations, to secure admission for his sick parishioners to each or all of the scores of voluntary hospitals and medical charities working within the Metropolis. There is no difficulty or doubt in his case, and there need be no delay, for the passport provided through the agency of the Hospital Sunday Fund is certain to secure the fullest attention and the utmost dispatch. There should therefore be, and there probably is, no need that an urgent appeal should be addressed to the clergy and ministers of religion throughout London, to cause them to specially exert themselves on Hospital Sunday in behalf of all the hospitals.

We said last week that only 40,000 people can be shown to have ever given anything appreciable to the London Hospitals, although one million patients and upwards were relieved by the voluntary institutions, exclusive of the relief afforded by St. Thomas's, St. Bartholomew's, and Guy's Hospitals, in the year 1885 alone. If one only of the many friends of each of the one million patients who were benefited last year by the voluntary hospitals would make up his mind to give one shilling to the Hospital Sunday Fund, £50,000 would be thus contributed from this one source. Surely so small a sacrifice may be demanded in the cause of charity.

In former years the clergy of all the churches had to fight the battle of the hospitals single-handed, but this year they have the full weight of public opinion behind them, and their collections should be at least double what they have been before. The Hospitals week has aroused very great attention, notwithstanding the excitement of the political crisis and the attractions of the London season. Politicians, physicians, dramatists, authors, statesmen, and the press, have all worked hard and with a will during the Hospitals Week. Is it too much to hope, despite the depression in trade, the numerous other claimants for subscriptions, and the absence of many wealthy residents from London, that the actual results on Hospital Sunday will this year far exceed anything yet accomplished. Three million people, as there are still in London, who as yet have neither used nor taken any interest in the Hospitals, is an exceedingly great army to handle. This thought should, however, move the preacher to higher flights of forcible and telling language, because the work is worthy of the cause; and the cause, of the advocacy of the ablest and best of men. If there are any that shrink from so great an effort, let them at least determine to persuade their own congregations to give just twice as much this year as they gave last. In this way the £80,000 can be raised without any great sacrifice on the part of individual citizens, whilst all the people will be able to fee, that they have done their duty.

We earnestly ask the clergy and ministers of religion to resolve to exert themselves to the utmost. To merely announce a collection, to take no trouble to ascertain what are the needs and claims of the hospitals, to leave an expectant congregation without an appeal for aid based on the facts, will be not only to neglect a great opportunity for good, but to injure the hospitals, to be unjust to the poor who need hospitals, and to the congregations, who cannot be blamed for not giving if the shepherd will not trouble himself to inform his flock of the pressing personal claims it is their duty and privilege to meet. Our fathers established and built the hospitals, of which we all claim to be proud. Will the clergy not step forward, a resolute and united band, determined to spend and be spent in the grand cause of securing ample means for the permanent sustenance of all the hospitals and medical charities of London. The laity have laboured during the Hospitals Week. The medical profession are always waging a fierce warfare with disease and death, day by day, and year by year. To-morrow it will be the day of the churches and chapels of London, and of the clergy and ministers who serve them. Will they not arouse the people to their plain duty and see at the same time that they do it also? There is not a single person in the land, no matter how exalted his station or how extensive his wealth may be, who can live and die without having to rely at some period of life on the aid of the hospitals, nor can any such person live without deriving actual personal benefit from the hospitals' work. We charge the clergy of all the churches, therefore, in all earnestness, to co-operate with medicine to-day, and, following the steps of their blessed Master and ours, to exert the influence of a love which He caused to be extended to all mankind, and of an eloquence which must prove overpowering, because it will urge the people in the sweet name of Charity to give substantial evidence of the effect which brotherly love must always exercise over men's minds. Let there be no re-enactment of the Parable of the Talents in any church or chapel throughout London to-morrow; for of clergy and people alike it may be said by the Hospitals, with truth, "Freely ye have received; freely give."

THE ORATION AT THE MANSION HOUSE.

MR. BRUDENELL CARTER said: As President of the Medical Society of London, at once the oldest and the most comprehensive of the various voluntary associations which have been established for the cultivation of medical science, I have been asked to lay before this meeting a summary of the conviction entertained by medical men with regard to the importance to the community at large of the efficient maintenance of hospitals. Before this audience, my Lord Mayor, it is, I hope, superfluous for me to dwell upon what the medical profession, the outcome and offspring of hospitals, has done, say only in the last fifty years, to promote the general welfare of the community. Lord Macaulay, in a well-known passage of his comparison of the England of the Stuarts with that of his own day, says: "Every bricklayer who falls from a scaffold, every sweeper of a crossing who is run over by a carriage, may have his wounds dressed and his limbs set with a skill such as, a hundred and sixty years ago, all the wealth of a great lord like Ormond, or of a merchant prince like Clayton, could not have purchased. Some frightful diseases have been extirpated by science, and some have been banished by police. The term of human life has been lengthened over the whole kingdom, and especially in the towns. The year 1685 was not accounted sickly, yet in the year 1685 more than one in twenty-three of the inhabitants of the capital died. At present only one out of every fifty inhabitants of the capital dies annually. The difference in salubrity between the London of the nineteenth century and the London of the seventeenth century is very far greater than the difference between London in an ordinary year and London in a year of cholera."

FORTY YEARS OF HOSPITAL PROGRESS.

Forty years have passed away since the passage which I have quoted was written; and the mortality among Londoners, last year, was reduced to one in every fifty-one of the inhabitants. This reduction has been partly due to the diffusion of sanitary knowledge, partly to the better treatment of occurring disease, and in both respects has been the direct outcome of hospitals. The great discovery of Dr. Budd, of the conveyance of the poison of typhoid fever by water, has shown us how to arrest its ravages; and the scientific researches of even the last few months point to the high probability that the source of scarlet fever will speedily be made known to us, and the ravages of that disease also will be checked (applause).

HOSPITALS AND THE ARMY.

A well-known physician, in an admirable address which he delivered this year to the students at Netley, sketched for them the histories of the Walcheran and Crimean campaigns, and drew a contrast between these and the recent campaigns in Egypt. In Walcheran, out of a garrison of 18,000 men, more than half died from disease within three months, so that the place was evacuated. In the Crimea, the total mortality among the British troops was 18,058, exclusive of those killed in action. Of this number 16,297 deaths were the result of disease alone, and only 1761 of wounds or injuries; and it is recorded that in the month of January, in the year 1855, nearly ten per cent. of the troops succumbed to disease. In 1882, out of 13,000 men serving in Egypt, nearly half of whom passed through the hospital, the total number of deaths, including 93 killed in action, was only 172. In the Suakim force, in 1885, with an approximate strength of ten thousand men, there were only 17 deaths out of 2047 cases admitted into hospital; and in the first Suakim expedition, out of 4000 men, with 314 admissions to hospital, there were no deaths at all (applause). In earlier Egyptian warfare, ophthalmia has been the great scourge of armies, and the French, in 1804, are said to have sent home 1000 men absolutely deprived of sight; while in our own recent campaigns in this country not a single man was blinded, although nearly 1500 cases of inflammatory affections of the eyes were admitted into hospital (applause).

THE EFFECTS OF HOSPITALS ON THE FAMILY.

While such have been the practical results of the teaching given in hospitals, when regarded from the most comprehensive point of view, I may be permitted to point out that the value of this teaching is not less conspicuous if we look at its effects upon the narrower circle afforded by every medical practitioner and his patients. Let us say that a labouring man breaks his leg. He is taken into one of the great London hospitals, and remains there for some weeks, tenderly nursed and cared for. At length he is discharged cured, and able shortly to resume his occupation. His earnings continue as before; and so a good work is done, the effects of which end, so far, with the benefit conferred upon the man, and upon his wife and family. But consider how greatly this good work is extended, and how much larger are its proportions, if the case affords the means of teaching, to each of fifty or a hundred students, something about the way in which such injuries should be treated; and thus enables each one of them to go forth into the world to encounter similar injuries in his turn, better prepared to deal with them than would otherwise be the case. Nor is it only the general or family practitioner, and the patients who are compelled to rely upon his skill, who are the gainers.

RICH AND POOR EQUALLY BENEFITED.

The teaching power is exercised over a much wider and more important area, in the influence which it has in furnishing the experience and skill which render the possessors of them the trusted advisers not only of the poor, but also of the rich. Without efficient hospitals as schools for students, we should have no capable general practitioners; and without them as schools for physicians and surgeons, we should have no men capable of performing difficult and delicate operations, or of investigating the most obscure conditions of disease. The circumstances which enable hospitals to become the centres of medical progress, and the great promoters of the growth of medical science, must on no account be misunderstood or misinterpreted. These circumstances are, mainly, the facilities which they afford for observation, whether of the natural history and events of disease, or of the action of remedies. Suppose, for example, that a physician wishes a certain observation, say of pulse, or of temperature, or of any other bodily phenomenon, to be taken with minute accuracy every half-hour. In private practice this would be almost impossible of accomplishment; in a hospital it at once becomes the duty of one of the clinical assistants. Suppose that the physician wishes the same observation to be made in the case of a large number of patients suffering from the same disease, and living within the same environment, but in other respects differing from one another. The hospital affords him at once the patients, the similarity of environment, and the skilled observers.

HOSPITAL PRACTICE EXPLAINED.

On various other occasions, when I have contended that the greatest use of hospitals is to promote the advancement of medical science, and to afford us improved methods of recognizing and of treating disease, I have been met by the well-meaning objection, "Oh, but it cannot be right to try experiments on patients," and I think it is worth while to look at this phrase more closely. Much turns, of course, on what we mean by the word "experiment," for, in one sense, it is an "experiment" to do anything which in any degree departs from precedent. But I may say, first, that what I may call the sacredness of the patient is a feeling which underlies the whole course of medical training and practice in this country, far more, I think, than in any other; and that no medical practitioner, certainly none whose previous career entitles him to be entrusted with the responsibilities of a hospital appointment, would ever either do, or sanction the doing, to a patient, of anything to which he would not himself submit in like circumstances, or which was

Digitized by Google

not, in his judgment, calculated to be beneficial (hear, hear). Experiment, in this sense of the word, is merely the application of previously acquired knowledge one step further, and hospitals allow such further applications to be made under the most favourable conditions. Sir James Paget once remarked to me, that when a new method of treatment was being put in practice at a hospital, the patients selected for it had always a better chance than others. Every one concerned, from the head physician or surgeon to the dresser or the nurse, was so anxious that the new method should be tried fairly, that, as a matter of fact, it was generally tried unfairly; the patients receiving from everybody something more than their share of watchfulness and attention.

Hospitals as Centres of Knowledge.

And now, returning to my original contention, that hospitals are more valuable to the community on account of the knowledge which radiates from them than on account of the actual relief which is afforded within their walls, considerable as this may be, I think it follows that I cannot call any form of hospital maintenance efficient which does not adequately provide for the accomplishment of this radiation. In order so to provide, it is necessary, first, that the physicians and surgeons should be selected on some principle which affords a guarantee of their skill and character; and, secondly, that the hospital should be freely open and accessible as a place of instruction, either for students or for practitioners. Such conditions, it is manifest, can scarcely be completely fulfilled in any but what are called "general" hospitals; and the ideal arrangement of hospital accommodation for London would be to place a sufficient number of general hospitals at proper intervals of distance, and to attach to them as many "special" departments as the interests of medical science might from time to time require. The hospitals should be large enough to keep down excessive establishment charges, and numerous enough to prevent the sick from being called upon to travel long distances (hear, hear). By way of contrast to this ideal arrangement, we have now in London eleven general hospitals, with very imperfect arrangements for the opening or variation of special departments, and placed very irregularly, some of them too near together and others too far apart; and we have seventy-one special hospitals, some large, some small, by which, whatever else may be done, establishment charges are almost indefinitely multiplied.

The Support of Hospitals a Matter of National Concern.

It follows, my Lord Mayor, if we must admit that the support of efficient hospitals is a matter of national concern, and not merely a matter of benevolence or almsgiving, that the public must be in want of guidance with regard to the directions in which their support should be extended. We have, in London, eighty-two real or so-called hospitals, most of them engaged, more or less, in a struggle for existence, and with every one of which the pecuniary and personal interest of many officials and servants are bound up. The tendency to survival does not appear to be in proportion to usefulness, but rather dependent upon the exertions and upon the qualities of the secretary and of the canvassers. It is certain that the money wasted by the multiplication of institutions, and by the machinery of appeals, would go a long way towards the supply of the real hospital needs of the metropolis. Is it possible, by any form of organization, to control hospital development in such a way as to obtain the maximum of good from the minimum of expenditure? An attempt in this direction was made some years ago by the Council of the Hospital Sunday Fund. I always disapproved of this attempt, which rested, in the first instance, upon a necessarily imperfect and misleading comparison between the expenditure of the several participating institutions; and at length I withdrew from the Council, on account of a decision to withhold the grant from a particular hospital on the score of certain alleged irregularities in its management. I thought then, and I think now, that the Council had not the means of discharging judicial functions, and that it was a mistake to take any step in the direction of entering upon them. There has, however, for some time past, been a prospect of legislation by which hospitals will be relieved from the burden of local rates; and if any such measure were passed, hospitals would have to be defined. Might it not be possible, in pursuance of a suggestion which I made several years ago, and which has been made independently by Mr. Burford Rawlings, to establish a sort of Board, containing both medical and non-medical members, to which the claim of any institution to be so relieved might be submitted, and by which such claim should be adjudicated upon? Might not the law require a sanction or licence from such a body as a condition precedent to the acceptance of legacies? There is yet one point more on which, by the indulgence of the meeting, I would dwell for a moment, and it is the question of out-patients.

The Out-patient System.

We have all seen written, and heard spoken, a great deal of elegant English in condemnation of what has been called the "out-patient system," and we have been told that out-patients are pauperized, and much more. Well, my Lord Mayor, all this reminds me of that book by Sir William Temple which was described by Macaulay as the best ever written by any man upon the wrong side of a question of which he was entirely ignorant (laughter). Out-patients, and plenty of them, are absolutely indispensable for medical teaching; and, if they failed to come willingly, it would be profitable to the community to pay them for coming (laughter). They consist of people who, at least apparently, are not very ill, and who, at all events, are not disabled. They enable physicians and surgeons to teach students to distinguish between trivial maladies and the beginnings of serious ones, and to treat both; and I need hardly say that a doctor is consulted about a trivial case much more often than about a grave one. If I were asked to define my ideal of a perfect family doctor, I should say it was furnished by the man whose habitual patients, coming to him about all small matters, were the least prone to severe diseases. A young practitioner would fail lamentably in his duties if he were able to recognize and to treat typhoid fever or profound organic disease, and yet could neither recognize nor cure some slight and common ailment. For the attainment of the latter kind of knowledge, and, therefore, for the attainment of practical usefulness in daily life, the study of the maladies of out-patients is a matter of imperative necessity (applause).

THANKS TO THE LORD MAYOR AND DR. WAKLEY.

At the Mansion House on Thursday the Rev. Dr. Rigg moved: "That this meeting is anxious to record a cordial vote of thanks to Dr. Wakley, the editor of THE LANCET, who, in his letter of the 22nd of March 1886, started this movement, and at the same time promised a further contribution of £1000 on condition that four other similar contributions were promised to the Hospital Sunday Fund before the end of July." He said this was one of those metropolitan subjects which were, of all subjects that came before the public, the most difficult to get hold of and to treat effectively. They were so vast, so varied, and involved so many relations and particulars which could not be reduced to any category, that to understand them in all their bearings was always a question of the most careful study, which every one was not able to give. The result was that there was inadequate information in regard to matters which of all subjects required the most perfect and particular attention. That was the reason why this movement had halted as it had done in past years. He hoped that the proceedings of that afternoon and of the coming Hospitals Week would lead to some suggestions in regard to co-organization and the means of bringing agencies to bear upon the subject which had not yet been heard of. London was one of the most philanthropic and generous cities in the world, and there must be underlying the whole of the metropolitan area a vast untouched fund of philanthropy which wanted to be reached. He hoped that the response to Dr. Wakley's generous offer would be large, and that the fund might by this means be raised from £30,000 to at least £60,000.

Digitized by Google

Captain PALLISER seconded the resolution, and hoped that they would soon have the pleasure of informing Dr. Wakley that his conditions had been complied with.

The resolution was unanimously adopted.

The DUKE of NORFOLK moved: "That a cordial vote of thanks be and is hereby given to the Right Hon. John Staples, Lord Mayor, President and Treasurer of the Metropolitan Hospital Sunday Fund, for the great energy and interest he has shown, not only in convening this meeting, but by devoting a large amount of time and thought to the organization of the Hospitals Week, and for his courteous and able conduct in the chair this day."

The resolution was carried by acclamation, and the proceedings terminated.

SIR ANDREW CLARK, BART., M.D., ON THE USE OF HOSPITALS.

THE following is an abstract of the address delivered by Sir Andrew Clark at Lambeth Palace on Monday, a full report of which will appear next week.

As Chairman of the Lambeth Palace meeting, Sir Andrew Clark said there was a happy congruity between the place and the purpose of the meeting. The place was the outward and visible symbol of the great work being carried on for the healing of the souls of men; and the purpose was the promotion of the work carried on in all the hospitals of London for the healing of the bodies of men. And he knew no two works between which so close a relationship subsisted. In the year just ended the London hospitals had given relief to a million of persons suffering from accident, injury, deformity, or disease; and they had been restored to health in such proportions as justified some pride in their work. But that did not represent the entire work done. Each person made several visits to the hospital, and the number he had mentioned might safely be multiplied by ten. Besides, Guy's, St. Thomas's, and St. Bartholomew's Hospitals and the work they did, were not included in this total (cheers). The work, too, was carried out under such a vigilant supervision as was not possible in the houses of the rich. He would confine himself to general hospitals. The men who did the work were picked men, and they exercised their functions not only in the face of the patients but under the eyes of the students, the sharpest of critics, and in the presence of the nurses; and they held themselves responsible to the public for seeing that the work was regularly, faithfully, and thoroughly done (cheers). It was for the sick poor, too, that the work was done. When they fell ill it was not only desirable, it was necessary, that they should have immediate admission to the wards of the hospitals where they were to obtain relief, and he was quite justified in saying, as far as the general hospitals were concerned, that their doors were always open whenever there was a case of sickness that needed assistance.

THE HOSPITALS ARE FREE TO ALL.

There was no difficulty about recommendation or about letters from governors; there was no condition required, except that the patient was ill and needed immediate admission to the wards. The patient was at once placed in the position most favourable to his disease, whatever it might be; he was put into a comfortable bed and was watched by skilled nurses, and whatever was found necessary for his relief was immediately provided for him. And still further, in most of these general hospitals, when a disease ended in recovery, and the patient was not left in such a complete state of restoration as to enable him to return to his family, he was taken away from the city to one of the pleasant convalescent homes in the country among the green fields, or to the sea, until his health was perfectly restored (cheers). Who were the recipients of this important work? Some of them had doubtless heard how much the general hospitals were abused, because their benefits were monopolized by those who had no right to them. He had been, he was afraid to say how many years, connected with the largest hospital in this country, for which Sir Edmund Hay Currie had done so much, and he did not remember an occasion when it was proved that a solitary person had passed through the London Hospital who was not sick and in need. The nearest approach to it was one case which he had vividly in his recollection. It was brought before him by one of those crotchet-mongers who, because they could not have the hospitals managed just as they would like, abused the way in which they were managed by others. He said it was a shame that they should have in their hospital a man who wore a tall hat and a frock-coat. The person he alluded to happened to be a poor clerk with 28*s.* a week, on which to keep a wife and a large family. Could anybody think that such a case was an abuse of charity? Those who were helped were the poor and the sick. They came from the slums of London, many dwelling in houses utterly unfit for human habitation. That was the work that was being done for over a million persons annually, and that was the work which he would still say was well done. And it was a work which he would show them bore enormous and important relation to the whole of society.

THE COST OF THE WORK.

What did it cost? He learned the cost from the pages of THE LANCET, and he must encroach upon their kindness to make some allusion to that journal. It had in years past done great service to hospital work. He was not sure, but he rather suspected that one of its proprietors was the originator of this work: of this at least he was certain, that from the day of its starting until the present time he had given it a very cordial support. He had hoped that their indefatigable supporter, Dr. Wakley, would have been amongst them to-day; but, alas! he was seriously ill; and he (the Chairman) was sure that he might, on behalf of all present, offer Dr. Wakley their warmest sympathy, and express the hope that he might be restored to health. He had learned from the pages of THE LANCET that the cost of the work to which he had referred was upwards of £490,000; but he regretted to say that it had not all been paid for. There was scarcely a London hospital that was not in debt for the work done for the sick and for the general public; and if the Divine function of charity was not to be extinguished amongst them, that debt ought at once to be paid.

THE IMPORTANCE OF HOSPITALS TO THE PUBLIC.

It had been said that the hospital patients were many of them improvident and vicious, and had brought their trouble upon themselves; that when they were healed they would soon go back again; and that the best thing to do was to leave them to fight their sickness at home. That might be good political economy, but it was not morality: it did not answer to the supreme moral obligation which told him, with an authority that he could not gainsay, that when a man was suffering and sick they should take care of him and succour him. But the work of hospitals was of still more importance to the public than to the hospital patients themselves. There was not an age or condition of life, there was not a disease or deformity, that was not favourably influenced by the work done in hospitals. It was not only that at present it benefited every member of society from the highest to the lowest, but it had been shown by figures which could not be disproved that hospital work had greatly lengthened the duration of life. It had strengthened the quality of mental work and made it more vigorous. It had reduced the mortality of London from one in twenty-three in the seventeenth century

Digitized by Google

to one in fifty-two or fifty-one, which was the rate at the present time; and it had made operations for diseases, which only twenty years ago were declared impracticable, the most successful in surgery.

THE HOSPITALS BENEFIT THE PUBLIC.

He had said that hospital work was more advantageous to society than to the sick poor. He would tell them why. Supposing a man was brought into a general hospital suffering from inflammation of the lungs. The physician would come into the ward and examine him in the presence of the pupils and of the nurses. The first object would be to learn what was the matter with the patient, and he would carefully examine him for that end. He would come to the conclusion that the patient had inflammation of the lungs, and then explain to the pupils the grounds on which he had arrived at that conclusion. Then he would proceed to point out what should be done for the man's relief or cure, and to explain the probable issue of the disease. From such work as that both the physician and the pupils derived benefit. Thus, the chief doctor, by discharging his duty in the presence of the pupils, was disciplined and trained to the highest possible capacity for undertaking the guidance and the treatment of the most difficult cases; and, in the second place, the pupils who stood around saw what was done, and so were steadily qualified for general practitioners, carrying away with them knowledge for the purpose, not only of supplying it to the sick poor, but also to the well-to-do and wealthy. And then as to the nurses: no one who had had any illness in his home could undervalue the enormous advantage of having a person of quiet demeanour and of well-disciplined knowledge, who understood that her duty was silently to observe what the doctor commanded her to do. He would repeat that perhaps the very greatest advantage that the hospitals conferred was not upon the sick, but upon those who stood aside and who only sometimes grudgingly gave to their support. They received all the benefit, but they did not pay for it. The hospitals were seriously in debt, and not only so, but year by year, almost month by month, the contributions that used to come in by hundreds of pounds were only coming in by pounds; and the contributions that used to come in by pounds were gradually being reduced to pence.

THE GREAT WORK PROCEEDS, BUT FUNDS DIMINISH.

The great work was going on, but the means by which they were to carry it out were almost daily diminishing. What was to be done in this conjuncture? There was only one thing which he knew of, unless the conscience of this great city could be awakened—that was that the hospitals must be closed or handed over to the State, and if any of them knew what handing over the hospitals to the State would mean—how it would deprive them of their inheritance, how it would fetter them, how it would turn living into dead hands—they would deny themselves some little indulgence rather than see such a disaster occur. Why did they not give? There were two answers to the question. First, it was said that hospitals were badly managed. He repeated, advisedly, that the general hospitals of London (he did not speak of the special hospitals) were well and economically managed. The other answer was, that times were bad and people could not give. True, trade was bad; but there were still in London crowds of costly equipages; receptions were more numerous than ever, and enough money was sometimes spent in flowers at a single reception to keep a hospital ward for a week.

ENGLAND'S CREDIT IN DANGER.

He did not believe in bad times. There was no lack of means; but there was a lack of charity, a lack of courage to live within one's means, so as to leave something for hospitals. It was not possible that such a state of affairs should continue, nor was it possible that the hospitals should be handed over to the State. What, then, were they to do? Of late they had shown themselves on one subject to be greatly patriotic; let them be patriotic in the desire that England should not lose her place in the modern hierarchy of nations. Was not that worth fighting for? Unless the mind of the country was aroused to its duty, it would, he feared, lose its rank, and be known as the country that did the least for the sick of any country in the world. That would indeed be a terrible humiliation. The strength of a nation was righteousness, and the strength of righteousness was charity. Let them give themselves to the discharge of that divine function, and so gain the strength that would carry them to the height of existence, where the life they would lead would be life indeed (cheers).

HOSPITALS WEEK MEETINGS.

THE MANSION HOUSE MEETING.

A MEETING to inaugurate the Hospitals Week was held at the Mansion House on the 17th inst., presided over by the Right Hon. the Lord Mayor. His lordship was supported by the Duke of Norfolk, Cardinal Manning, Sir Wm. McArthur, Sir E. Currie, Hon. and Rev. Canon Leigh, Col. Haygarth, Capt. Palliser, Rev. Canon Nisbet, Rev. Dr. Herman Adler, Mr. Brudenell Carter, Mr. Henry C. Burdett, Rev. R. C. Billing, Rev. Dr. Allon, and many other friends of the movement.

The LORD MAYOR, in opening the proceedings, said the origin of this special effort was to be found in a suggestion made by Dr. Wakley as far back as the 22nd of March. London had been divided into six districts, and arrangements made for meetings to take place daily during the week preceding Hospital Sunday. The present meeting was for the purpose, if he might so say, of commencing the inauguration of the grand movement for putting the Hospital Sunday Fund in the position which it ought to occupy in the city (applause). Up to the present it had not quite fulfilled the desires which they all entertained respecting it. When the Hospital Sunday Fund was commenced it was a novelty: the results at the time were satisfactory, but they did not show that continued improvement which they had a right to expect. Undoubtedly there was always a great difficulty in obtaining a sympathetic movement over the whole of London, no matter what the object might be: the inhabitants were different in their manners and customs; their feelings were occupied in different directions; in fact, they were so many distinct and different cities. By the means proposed it was hoped to promote the bond of sympathy which the very mention of the Hospital Sunday Fund ought to excite in the breast of every thinking man. He concluded by expressing his earnest and sincere hope that the movement thus commenced would be productive of thoroughly beneficial results on the extended scale that everybody must desire (applause).

Cardinal MANNING moved the first resolution: "That this meeting, to inaugurate the series of public meetings to be held in various parts of London during the six days immediately preceding Hospital Sunday, June 27, desires to arouse a far greater feeling of sympathy and co-operation in support of the hospitals and medical charities of the metropolis. The co-operation of the clergy and ministers of all churches and chapels, and of those eminent public men who have generously consented to speak at the meetings in the Hospitals Week, having been already obtained, the success of this combined movement will now largely depend upon the support extended to it by the editors of the metropolitan daily press, who can secure full reports of the proceedings at the meetings, so as to enlist the sympathies of all classes of the people throughout London, and thus add to the already numerous favours which they have conferred by ably advocating the cause of

Digitized by Google

Hospital Sunday since its establishment in 1873." He said the Hospital Sunday Fund had been in existence thirteen or fourteen years, but the result year by year had not in any degree corresponded with the measure of increase which might justly have been looked for, and therefore a new effort, as the Lord Mayor had stated, was absolutely necessary. The mortality of London was from 70,000 to 80,000 every year, and the amount of sickness that that number of deaths would represent must be very large. It was to meet not only the mortal cases, but cases of sickness of all kinds, that the extension of their hospital system was absolutely required. The London hospitals, many and large as they were, would not contain more year by year than about 50,000 or 60,000 in-patients, assuming that there was a continual succession in the beds, and that they were occupied for something like an average period. Comparing this with the mortality and sickness, and also with the vast population of London, for which provision must be made, it seemed that as yet they had no adequate provision for the sickness and the suffering of that population. That point being established, he hoped they would not content themselves by saying that they had a very large and efficient system of hospitals. A great many people had lulled themselves to sleep with the notion that provision was already made. It was not already made; and that must be fixed as the first axiom in dealing with this question. When they considered the enormous increase of the wealth of London, and compared it with the amount collected for the Hospital Sunday Fund—about £30,000 or £32,000 every year—they must all feel that there was some defect, some want of motive power, some deficiency, he would not say of good will, on the part of those who had assisted in this movement—for that he was confident was not the fact—but that in some way they had not reached the consciences and the hearts of the people of London sufficiently. That being so, it would seem that this resolution required no further justification. It, first of all, appealed to the ministers of all denominations; it, secondly, appealed to all laymen; and, thirdly, to the press, and to all those who were able to give publicity to and enforce by comment the proceedings which would take place at the meetings about to be held. As yet they had not reached the hearths and the homes of the people at large, and the Hospital Sunday Fund was the best possible means of securing such a result. He had great pleasure in moving the resolution.

Mr. HENRY C. BURDETT said that, so far as could be ascertained from the published reports of the Hospitals and Medical Charities of London, the names of only 40,000 separate individuals were to be found within their pages—that was to say, that not more than one person out of every 100 in London contributed anything definitely to the hospitals. The Hospital Sunday Fund up to that time had been mainly, so far as the organization in London was concerned, the work of the clergy and ministers of all denominations. They were now met to inaugurate a new departure, the success of which would be largely due to the devotion, the time and the energy that the Lord Mayor had thrown into the matter (applause). It was a new departure on the part of the laity, who felt that the clergy ought to have behind them, and to be encouraged by feeling that they had behind them, the support of public opinion (applause). Notwithstanding the political crisis through which they were passing, leaders of political parties on both sides would be found on their platforms at the district meetings, and not only politicians, but other leaders of public opinion, showing that really and truly the laity desired to co-operate with the clergy, and to show by combined action the importance which they attached to the financial straits in which many hospitals of London were placed. He wished to state that in connection with this movement the proprietors of THE LANCET, to whom the hospitals were under great obligation, had sent a special commissioner, a trained correspondent, who had been in many countries and had seen many things, to visit the hospitals, and he came back with this conclusion. Having visited all the leading hospitals, both special and general, he maintains that the reason that there is not more financial support at the present time from the majority of the people of the metropolis is solely due to the one fact that they are ignorant of the work done within the hospital walls. If that statement was correct, as he believed it to be, he felt that this Hospitals Week, this new departure, by attracting the attention of all classes of the community to the needs of the hospitals, would do a real service—indirectly by increasing the amounts collected on Hospital Sunday, and also directly by arousing people in all parts of London to the fact that the medical charities which were to be found in their midst required further support. No doubt if this awakening be secured, all classes would then give further support, especially if the managers of the various medical charities approached them individually after Hospital Sunday was past and over.

The resolution was unanimously adopted.

MEETING AT LAMBETH PALACE.

THE first of the six district meetings was held on Monday afternoon in the library of Lambeth Palace, under the presidency of Sir Andrew Clark, M.D., F.R.S.

Mr. R. KESKIN (by whom the meeting was organized) read a letter from Lord Sandhurst, expressing regret at his inability to attend; and another from Dr. Oliver Wendell Holmes, expressing sympathy with the movement, and his regret that he could not multiply himself so as to be in London and Oxford at the same time, it being absolutely necessary that he should be in the latter place.

Mr. OCTAVIUS MORGAN, M.P., moved the first resolution: "That this meeting pledges itself to use every endeavour to arouse the inhabitants of this district of London to the importance of maintaining the hospitals and medical charities in the utmost efficiency; and in furtherance of this object it urges the clergy and the ministers of religion to make an earnest appeal to the people to so increase their contributions on Hospital Sunday as shall secure that the whole sum collected shall not be less than £80,000." The hon. member urged all the electors present to do their utmost to return such members to Parliament as would be indefatigable in their efforts to pass the Bill for the relief of hospitals from local taxation.

Sir EDMUND HAY CURRIE, in seconding the resolution, said he could not help thinking that if the mind of London could be once made to grasp the fact that the hospitals were falling into debt to the extent of £40,000, that amount would be quickly forthcoming. He then suggested that appeals should be made to the country towns, which sent so many patients up to the London hospitals for relief.

The Rev. CANON CLARKE said that from practical experience he could testify to the valuable work done in London by the hospitals. He was very much afraid that if they were ever handed over to the State, all the religious element which was so indissolubly connected with them as a charity would disappear. He was sure that all clergymen would do their very best to further the work.

The Rev. Dr. LEE having made a few remarks in support of the resolution, it was put and carried.

General C. FRASER, M.P., moved the next resolution: "That this meeting regrets to learn that the expenditure and liabilities of the hospitals and medical charities of this district in the year 1885 exceeded the income by £2000, and pledges itself to increased exertion, with a view of preventing any like deficiency during the current year." He said he believed that the people only wanted a thorough awakening to a sense of their duties towards hospitals to lead them to give a more liberal support.

The Rev. NEWMAN HALL seconded the resolution, and the Rev. F. G. PELHAM supported it. It was then put and unanimously adopted.

On the motion of the Rev. W. EDWARDS, a vote of thanks to the Archbishop of Canterbury, for granting the use of the library of Lambeth Palace for the meeting, was unanimously agreed to.

A vote of thanks to Sir Andrew Clark for presiding was also carried.

WORK FOR ALL—A GOOD IDEA.

Sir ANDREW CLARK, in returning thanks, said he had attended with the greatest pleasure, and he deemed it a privilege to be allowed to join in the work. He had one suggestion to make. As women enjoyed much less vigorous health than men, which was to a great extent to be accounted for by the want of a definite purpose in life, his suggestion was that a Hospital Sunday Society might be formed in every parish, which should put on a permanent basis the work they had established. In the operations of these societies employment might be found for women, who would thus be kept in constant healthy work, and at the same time would be adding to the funds of the hospitals. He commended this proposal to the clergy and ministers of religion throughout the metropolis, who could easily arrange for a body of gentlemen to act as joint Honorary Secretaries to this Congregational Hospital Society. Each society might then communicate with the Hospitals Association, Norfolk House, Norfolk Street, W.C., which would guide the societies in the right way to make the Hospital Sunday Fund a continuous and abiding success.

MEETING AT BLACKHEATH.

THE second district meeting was held at the Rink Hall, Blackheath, on Tuesday evening, the chair being taken by the Earl of Dartmouth.

Lord DARTMOUTH, in opening the proceedings, said that on Sunday next there would be collections in aid of hospitals in every place of worship within the metropolitan area. In the particular district in which the meeting was held interest would especially centre in two well-known and deserving institutions—the Seamen's Hospital and the Miller Memorial Hospital at Greenwich. Foreign Governments took immense interest in the Seamen's Hospital, and as a proof of that he might mention that the German Consul-General and the Austrian Vice-Consul were both present at the annual meeting in March last. Canon Miller was one of the first who founded the Hospital Sunday at Birmingham in 1859, and therefore it was appropriate to give the institution his name. He hoped that many people would take the trouble to read the story, which he believed was entirely founded on fact, in THE LANCET Special Supplement, entitled "Within the Hospital Walls," because he was sure that if they began to read it, they would not only feel interested, but intensely touched by what they read. He himself had been greatly affected by the account, which appeared in the Supplement of THE LANCET of last Saturday, of the old bird-catcher who met with an accident in the street, and was brought to the hospital to die, and who left his birds to the hospital. If such stories were generally known, all classes of the community would be encouraged to support liberally the hospital funds. Even those classes who were not obliged to seek shelter in hospitals derived benefit from the fact that efficient medical men and nurses were trained there. It was sometimes said that the more opulent classes of society used the hospitals in order to have their domestic servants relieved when they were struck down by accidents; but if there was one class in the community more than another that required the help of a hospital it was domestic servants. The late Mr. Robert Grimstone met with a serious accident in the hunting-field, became an in-patient of a London hospital for some time, and with his usual generosity he took care never to forget the benefits that he received there. An accident in the streets might happen to any one, and if that person had no indication about him as to his residence or personality, where could he be taken to except to the nearest hospital? Hospitals, therefore, were useful to all classes of the community. In that district it was right that they should remember what the needs and necessities of the various hospitals and dispensaries were. During the year 1885, in the hospitals and dispensaries of No. 2 district, there were 2505 in-patients and 45,785 out-patients, making a total of 48,290 patients treated. Of these, 40,383 were district, and 7,907 non-local cases. The gross income of the institutions was £25,306, and the gross expenditure £35,004, leaving a deficiency of £9689. He hoped that ministers of all denominations would vie with one another in honourable rivalry as regards the collections next Sunday. This was an occasion when people of various creeds and of different politics, and of all ranks and stations, were called upon to take their part in providing for their fellow-creatures.

Baron HENRY DE WORMS proposed the first resolution: "That this meeting pledges itself to use every endeavour to arouse the inhabitants of this district of London to the importance of maintaining the Hospitals and Medical Charities in the utmost efficiency; and in furtherance of this object it urges the clergy and ministers of religion to make an earnest appeal to the people to so increase their contributions on Hospital Sunday as to secure that the whole sum collected shall not be less than £80,000." He said that the income of the London Hospitals had materially diminished during the past year. If he wished to find the reason for that diminution he would seek it not in any wish or idea on the part of the general public to withhold their subscriptions, but in the fact that there unfortunately existed at the present time in England a terrible depression of trade. He could not agree with an eminent physician, who sought the reason for the diminution in the subscriptions to hospitals in excessive extravagance in other directions. He quite agreed that a man or woman who indulged in luxury beyond his or her means did a reprehensible act, but it should not be forgotten that if those who had the means did not indulge in such expenses commensurate with their income, those who were not so wealthy would suffer. No doubt Sir Andrew Clark's object was a good one, but he (Baron de Worms) regretted that the reasons given by that eminent physician did not commend themselves to the minds of some of the public. Still, the point to be considered was not the abstract opinions of the advocates of the cause, but how the good cause could be best forwarded. No less than an additional £80,000 a year was required for the hospitals of London. At the Ophthalmic Hospital, in Moorfields, there were about ten operations a day, or 3,650 in a year, and nearly £300 worth of spectacles were distributed to the poorer classes. In another hospital there were 8,000 accident cases dealt with last year. Of that number, 2,000 were in-patients, and the expenses of the hospital were £50,000 a year, while its certain income was only £15,000. It was to cover the deficit in various hospitals that these meetings had been inaugurated, and he hoped that they would be attended with material success. There were many, who called themselves philanthropists and reformers, who conceived that they had a panacea for every ill which existed, but were too ready to set class against class, and to forget that the great object was to assist men in the hour of need. Carlyle had very well described the action of those loud-mouthed philanthropists who simply did good in word but not in deed, when he said, "England has, I am persuaded, in it many kings; they are among the silent, I believe, mostly far away from platforms and public palaverings, not speaking forth the image of their nobleness in transitory words, but imprinting it, each in his own little section of the world, in modest, kindly actions that will endure for evermore." Those words contained the true spirit of philanthropy. Those who thought that the more prosperous classes in England neglected the less prosperous should bear in mind this great fact, that England was the only country in the world where nearly every hospital was supported by voluntary contributions. The hospitals were the silent, true tribute of the generous men and women who freely, for their suffering fellow-creatures, were willing to give according to their means to help those who were less fortunate than themselves. The helping hand of the rich was the safeguard of the poor. Perhaps many people had never seriously considered what the great hospitals in London did. There were in the metropolis four and a half millions of people. It was difficult to imagine what suffering must be endured by that great mass of humanity. Poverty itself was hard enough to endure; but how much harder was it when it was coupled with disease! No person who considered what it must mean to the poor, living in hovels, to have a child stricken down by fever, without the means of obtaining the precious aid of science, would hesitate to give according to his ability to maintain the great

Digitized by Google

charitable hospitals of London. He well recollected the marvellous description of the Children's Hospital which was given by Dickens. It appealed to the "one touch of nature which made the whole world kin;" and mentioned how the child was taken to the hospital with its toys, and how the doctor, knowing by instinct what the child thought, transferred the toys from the table in front of its bed to the next cot; and then the little child, having bequeathed everything it had to leave in this world, left it. Similar scenes were enacted every hour and minute in the great hospitals of London. It was on behalf of such sufferers that he invoked the charity of the public.

Mr. STRONG, M.P., seconded the resolution. He said that the fact that over one million persons were annually relieved by the voluntary hospitals showed that at least one quarter of the inhabitants of the metropolis were directly interested in those institutions. Hospitals were too often regarded merely as places entirely devoted to rendering aid in case of accident, but there were surgical cases which it was almost impossible to treat in private houses. He also wished to mention the dispensaries, where the working classes, on payment of a small weekly sum, could obtain efficient medical assistance. Such institutions inculcated habits of thrift and self-reliance. It was the opinion of many practitioners that one out of every ten of the adult population of London used surgical appliances, and such appliances were distributed in thousands among the poor. Modern Londoners had not done their part in this great work, but he trusted that the time had now arrived when it would be brought home to the minds of all, that if they did not assist in supporting the hospitals, they would be neglecting a great duty.

The Rev. C. WILSON supported the resolution. The public, he said, were under obligation to hospitals because they were the means of training nurses, who, besides serving in the hospitals, were of the greatest value as auxiliaries to medical skill in the nursing of private patients. Every donor of ten shillings would have the satisfaction of knowing that he paid for one patient for one year at the rate of the average cost. An important element omitted from the hospital statistics was the amount of pauperism prevented by the medical relief afforded by the hospitals.

The resolution was unanimously agreed to.

Baron F. DE ROTHSCHILD moved the next resolution—"That this meeting regrets to learn that the expenditure of the hospitals and medical charities of this district in the year 1885 exceeded the income by £9698, and pledges itself to increased exertion with the view of preventing any like deficiency during the current year." He said that the rapidly increasing population of London necessarily increased the expenditure of the hospitals, while the advance of medical science increased the means of dealing with the diseases attending overcrowding and accidents in busy towns. The support of hospitals did not meet the demands upon them; and it was feared that some of the smaller ones would have to be closed, and the larger ones diminished in usefulness, unless their funds were increased. Some of the smaller hospitals were not managed with due economy. They had expensive officials and boards, with a small number of patients. He hoped that public attention would be called to the matter, and that such institutions would consent to become merged into larger and more useful ones. One of the reasons for the serious diminution in the contributions was no doubt due to the fact that recently so much had been done for the labouring classes that philanthropists were no longer able to continue their large subscriptions to other objects. He sincerely hoped, however that on Saturday and Sunday the wealthy would come forward with their gold, and the working-classes with their silver and copper, for the hospitals by which they so largely benefited.

The Hon. and Rev. CANON LEGGE seconded the resolution, which was supported by Mr. H. C. BURDETT, and agreed to.

The proceedings closed with a vote of thanks to the Earl of Dartmouth for presiding.

HOSPITAL SUNDAY SUBJECTS AND PREACHERS.

THE following is a list of the subjects of sermons to be delivered in the respective places of worship to-morrow, on behalf of the Hospital Sunday Fund:—

St. Jude's, South Kensington.—By the Rev. R. W. Forrest, D.D. At 11 a.m. and 7 p.m.

St. Luke's, West Holloway (Rev. Richard Glover).—At 11 a.m.: "Wrath and Mercy as seen in Sickness." At 7 p.m.: "The Good Samaritan as an Example."

St. Martin in the Fields.—Sermons will be preached at 11 a.m. and 3.30 p.m. by the Vicar; at 7 p.m. by the Rev. W. P. Pearce.

Parish Church, Mitcham.—By the Revs. D. F. Wilson and J. M. Braithwaite.

Congregational Church, North Finchley (Rev. T. Hill).—Morning: "And Jesus went forth, and saw a great multitude, and was moved with compassion towards them, and he healed their sick." Evening: "Bear ye one another's burdens, and so fulfil the law of Christ."

Wood-green Congregational Church (Rev. W. G. Horden).—At 11 a.m.: "The Influence of the Christian Religion on the Healing Art." At 6.30 p.m.: "The Connection between Disease and Sin."

Congregational Church, Park Road, West Dulwich, S.E. (Rev. A. C. Tarbolton).—At 11 a.m.: "The Christian's Debt to the Hospital" (Matt. x. 8). Afternoon at 3. Evening at 7: "Philanthropy by Proxy" (Luke x. 35).

Trinity Road Congregational Baptist Church, Upper Tooting (Rev. D. Llewellyn).—"The claims of the Hospitals upon the Church."

Islington Presbyterian Church, Colebrooke Row (Rev. T. Davidson, D.D.).—At 11 a.m.: "The solitary case of a Deaf and Dumb Man Cured by Christ."

Agricultural Hall, Islington.—At 3.30 p.m.: "The Right Sort of Sympathy."

Bayswater Synagogue.—On the 26th inst., at 10.15 a.m., a sermon will be delivered by the Delegate Chief Rabbi—"A Plea for the Sick and Suffering."

St. Paul's, Great Portland Street.—By the Revs. H. Bickersteth Ottley and C. J. Williamson.

St. Luke's, Hackney.—By the Rev. W. H. Langhorne.

Holy Innocents' Mission, Hammersmith, W.—By Revs. H. C. Eden and J. H. Cardwell.

Bloomsbury Chapel, W.C.—By the Revs. W. J. Benham and J. P. Chown.

St. Stephen's, Southwark.—By the Rev. William Dodge—"The Good Samaritan."

The *Hospital Chapel* (*St. Mary and St. Thomas of Canterbury*), *High Street, Ilford.*—At 11 a.m. and 6.30 p.m. by the Rev. W. H. Penney, M.A.; at 4 p.m. by the Rev. A. Ingleby, M.A.

West Norwood Congregational Church, Chapel Road, S.E. (Rev. S. King).—Morning, at 11: "Brotherly Kindness the Evidence of Indwelling Love." Evening, at 6.30: "Society Weighed in the Balance."

THE HOSPITALS WEEK.

The following Meetings have yet to be held:—

FRIDAY, 25th June.—*Highbury Athenæum*, 8 P.M.
President—The Duke of Westminster, K.G.
Speakers—Mr. R. Chamberlain, M.P.; Mr. Ince, Q.C.; Mr. Waddy, Q.C.; Mr. Bartley, M.P.; Mr. Cowley Lambert; Dr. Buchanan; Sir Dyce Duckworth, M.D.; Mr. Murdock, M.P.; Mr. Bigwood, M.P.

SATURDAY, 26th June—*Stratford Town Hall*, 4 P.M.
President—H.R.H. the Duke of Cambridge.
Speaker—The Marquis of Salisbury, K.G.

SPECIAL NOTICE.

IT is requested that a statement of the total amount of each collection made on Hospital Sunday, together with the names of all individual donors of £5 and upwards, may be forwarded to THE LANCET Office, Strand, W.C., by Tuesday next at latest.

NOTICES TO THE CLERGY AND MINISTERS OF RELIGION.

Free copies of this Special Supplement may be had on application by any clergyman or minister of religion who may require them for distribution amongst the more wealthy members of his congregation.

It is requested that an abstract of special sermons to be preached in aid of the Hospitals at any of the services on Hospital Sunday, June 27th, may be sent to the Editor of THE LANCET, 423, Strand, W.C. All such notices should reach this Office not later than Tuesday, June 29th, in time to appear in the Third Special Supplement, which will be issued with THE LANCET of July 3rd.

—— mission week, a, 801, 1085
—— nurses, lectures to, 413
—— Saturday Fund, 89, 283, 379, 474, 906; in Birmingham, 1032
—— Sunday Fund, 599, 943, 1193; and the theatres, 1132, 1230
Hospital Sunday, 1226
Hospitals, contributions to, 27; Christmas in the, 80; rating of, 503; and their claims, 703; street collections for, 1036; alcohol in, 1136, 1190; and Londoners, 1169; and provident associations, the abuse of, 163; Association, the, 45, 767, 797, 1003
Hospitals Week: First Special Supplement of THE LANCET, 1193; Second Special Supplement, 1249
Hot baths, hot packs, and pilocarpine compared, 1133
Hot drinks, influence of, on digestion, 220
Hottentot pathology, 49
House of Commons, late sittings in the, 656; vaccination and the, 701
Houses, insanitary, 184; let in lodgings, 982
—— of Parliament, sewer air in the, 757
Howard and Sons, Messrs., cinchona preparations, 127
Hudson, Mr. C. T., the Rotifera or Wheel Animalcules (review), 595
Huggard, Dr. W. R., on Mr. Horsley's criticism on Professor Schiff, 177, 375, 550
Human body, electrical conditions of the, 730, 820, 863, 1025
Humerus, compound fracture of the, implicating elbow-joint, 154; cylindrical cancer of, 349; compound fracture of, with wound of shoulder-joint, recovery, 874; with split fracture into elbow-joint, 875
Humphry, Professor, on flat foot and the construction of the plantar arch, 529
Hunt, Mr. R. E., on cephalalgia with cataleptic symptoms, 94
Hunter, Dr. W. B., on a large calculus, 132
——, John, the house of, 75; unveiling the statue of, 1036, 1078; the home of, 1230
——, William, the school buildings of, 951
Hunterian Society, 284
Hutchinson, Dr. C. F., on dry dressings for internal cavities, 300, 720
——, Mr. J., on some moot points in syphilis, 65, 157, 252; on relapsing cyclitis, 742; Lettsomian lectures by, 359, 407; on the New Sydenham Society, 1140
Huxley, Professor, theology of, 749
Hyaline degeneration, 458
—— prostatic casts, 120
Hydatids, multiple, 802
Hydrastin, 990
Hydrocele, corrosive sublimate for, 35; the radical cure of, 692
Hydrology and climatology, the international congress on, 894
Hydronephrosis, 68; traumatic, 689
Hydrophobia, 78, 1103; Russian remedy for, 45; rational treatment of, 60, 235, 469, 900; old prescriptions for, 93; prophylaxis of, 118, 171; a plan of treatment proposed, 335; Prof. Pasteur and the prevention of, 552, 609, 657; and the dog regulations, 604, 706; deaths from, 635, 704; Buisson's treatment of, 655; and the treatment of bites of rabid animals by suction, 782; a case of so-called, 821; pathological histology of, 876; fresh suggestions, 909; alleged cure of, by sweating, 1037; in Paris, 427; in Holland, 893; the commission on, 600, 1082
Hygiene, the International Congress of, 223
Hyperidrosis, 141, 186
Hyperpyrexia, case of post-mortem, 103
Hypnone, 466
Hypodermic injections, high nursing and, 1189
"Hypopion" and "Hypopyon," 85
Hyslop, Dr. J. M., Pendjeh sore, 1191
Hysteria in soldiers, 707
"Hysterical fever," 940
—— pyrexia, 351
Ice accidents, 118
Ichthyosis fœtalis, 657
Idiots Bill, the, 656
Illegal drug selling, pernicious effects of, 845
Iliac, aneurysm of external, successful ligature of common iliac artery for, 444
Ileus, two cases of, occurring in brothers; employment of tobacco; recovery, 1220
Illingworth, Dr. C. R., on dysmenorrhœa, 142; on paralysis agitans and cephalalgia, 234
Imagination, can it kill? 1175
Imbecility with choreoid movements, 1021
Impregnation, unconscious, 361
Incompatibles, 672
India, report on the sanitary measures in, in 1883-84, 224
Indian health statistics, 849, 896
—— hemp in dental operations, 1180
Inebriates, the Dalrymple Home for, 427, 986
Inebriety, Society for the study and cure of, 90, 695, 1099
Infant feeding, 756; cod-liver oil, 861, 1006
Infection, spread of, through elementary schools, 123; and registration, 1034
Infectious cases, trained nurses in, 900
—— diseases, home and hospital treatment of, 166, 419; medical risks from, 273; Act, prosecution under the, in Sunderland, 621; provision against, 1235
Infectious hospitals in rural districts, 215
Inflammatory process, the, 337
Ingleby lectures, 1055, 1105, 1151
Inguinal aneurysm, traumatic rupture of sac, ligature of arteries, 447
Inhalation, new method of, and new form of apparatus, 192
Innominate artery, aneurysm of the, 18; on compression of the, 481; ligature of the, 656, 1064
Inquests the uselessness of, without post-mortem examinations, 267
Insane, surgical affections in the, 987
Insanity, no evidence of, 944; and crime, 1083
Internal cavities, dry dressings for, 720
International Medical Congress, 35; the American Medical Association and the, 799
—— Congress of Hydrology and Climatology, 174
—— Journal of the Medical Sciences (review), 404
Intestinal juice, the digestive powers of, 214
—— obstruction, the significance of collapsed bowel in operations for, 1177
—— stricture, double, 876
Intestine, perforating ulcer of the, 395
Intoxication, apparent, 1135
Intra-cranial abscesses, idiopathic, 705
—— tumours, 251, 687; at the Pathological Society, 271
Intra-pulmonary antisepsis, 168
Intra-uterine amputation with other deficiency of parts, 855
Intussusception, on inversion with inflation in the cure of, 98; acute, inflation and injection of bowel, recovery, 63; multiple, 350
Iodide of potassium, use of, in aneurysm, 476
Iodoform and nitrate of silver in indolent ulcers, 1087
—— spray, 1103, 1247
Ireland, Dr W. W., the Blot upon the Brain (review), 258
Ireland, sanitary improvements in, 890
Iris, atrophy of, 254; new formation of pigment on anterior surface of, 742
Irish Medical Association, 1181
—— Medical Schools and Graduates' Association, 611
Irritant poisoning, death from, 706
I's and Y's, 178
Isthmus of Panama, sanitary condition of the, 1133
Italian Home Office on cholera in 1884-85, 84
—— hospital, Constantinople, the, 271
Italy, legal medicine in, 800; quarantine in, 985; cholera in, 1135

Jackman, Mr. W. T., on fracture of base of the skull, with optic neuritis, 685; on traumatic tetanus, successfully treated with chloral hydrate in conjunction with urethan, 1112
Jackson, Mr. Henry, obituary notice of, 1049
Jacob, Dr. E. H., on death from ether, 809
Jalland, Mr. W. H., on large fibroid tumour of the uterus, 207; on rotheln, a point of diagnosis, 855
Japan, a health department for, 138
Jarrow, health of, 1043
Jaundice, itching of, 50; persistent pigmentation after, 742
Jaw, secondary epithelioma of, 975
"Jaw-jerk," the, 220
Jeaffreson, Mr. C. S., application of the electric light to the ophthalmoscope, 328; on cataract, 387, 434, 479
—— Mr. John Blackett, obituary notice of, 136
Jeffreys, Mr., presentation to, 812
Jejunum, intussusception of upper part of, 448
"Jemimas," 186
Jena University, legacy to, 1037
Jenner, Sir William, 600
Jennings, Mr. C. E., on excision of the entire uterus for cancer, 682, 825
Jersey General Hospital 705
Jervis-street Hospital, Dublin, 283
Jessett, Mr. F. B., on two cases of amputation of the penis for epithelioma, 963
Jessop, Mr., the accident to, 1180
Johns Hopkins bequest, 369
Johnson, Dr. G., testimonial to, 1036
——, Mr. J., on ventilating sewers, 669
Joints, inflammation of, following injury to spine, 613; injuries to, 789
Jones, Dr. H. W., on intermittent albuminuria with oxaluria, 432
——, Mr. P. S., health-resorts for phthisical patients, 714
——, Mr. T. W., the Darwinian working hypothesis of evolution, 341
Journal of Anatomy and Physiology (review), 356
—— of Heredity (review), 836
—— of Mental Science (review), 113, 835
—— of Physiology (review), 113, 452, 836
Judge, Mr. M. W., on sanitary legislation, 809
Julius, Dr. Frederic Gilder, obituary notice of, 136

Digitized by Google

Jurymen, the, would have their way, 411; incapacity of, to serve, 753

Keetley, Mr. C. B., an Index of Surgery (review), 113
Kempe's Medical Book-keeping (review), 23
Kennedy, Dr. Evory, obituary notice of, 556
Kennedy's extract of pinus canadensis, 804
Keratitis, acute, note on, 762
Kerr, Mr. J. L., on the treatment of pertussis, 327
Kettering, health of, 658
Kidderminster Infirmary, 389
Kidney, contracted granular, fatal case of, 199; abscess of, communicating with bowel, 201; calculi in, 306; congenital cystic, 445; a case of rupture of the, 486; congenital adeno-sarcoma of, 542; disease of the, cardiac hypertrophy and, 783; abscess of, treated by frequent tappings; recovery, 919; villous disease and rupture of, 928; case of exploration of the, for suspected calculus, 1112
—— anomalies, 894
Kidneys, unstriated muscle in the, 507
Kilgarriff, Mr. Malachy J., obituary notice of, 1002
King, Dr. Kelburn, obituary notice of, 136,
King's College Hospital, 427, 557, 1084
—— Norton district, health of, 710
Kirby, Dr. E. A., on phosphorus, 671
Kirk, Dr. R., on a new syringe or injector for surgical purposes, 873
Kissing the book, 527, 861, 910, 959
Klein, Dr. E., on the etiology of foot-and-mouth disease, 15
Kleptomania, 1035
Knee, dislocation of the left, 105; symmetrical synovitis of the, in hereditary syphilis, 391
Knee-joint, excision of the, 2; of a patient aged eighty years, large loose cartilage successfully extracted from the, 302; gunshot injury in the neighbourhood of the, 389; antiseptic irrigation of the, 597; excision of, 833; two new bursæ at the, 1180
Koch's bacilli in Addison's disease, 863
—— gelatine peptone water test, 880
Kuttner, Dr. Karl Friedrich, death of, 990

Labio-glosso-laryngeal paralysis, with atrophic paralysis of the hands, 305
Labour, anatomy of, 547
Labourers Act (Ireland), the, 813
Lacey, Mr. A. R., on the new College of Surgeons and Physicians, 478
Lacrymal syringe and cocaine hypodermic injector, 646
Lady doctors in Italy, 45
—— medical missionaries, 802
—— probationers, 153
Laffan, Mr. J. G., on a method of controlling bleeding during excision of the tongue, 571
Lamps in bedrooms, 23
Lanchester, Dr., the late, memorial to, 5
Lane, Mr. W. A., Manual of Operative Surgery (review), 1223
Lardaceous hepatic disease, 109
Large fee and a munificent donation, 657
Laryngeal cortical centre, 988
—— muscles, paralysis of, 985; and cortical centre, paralysis of the, for phonation, 1045; pathology and physiology of the, 1076
Laryngotomy, recovery, 738
Late closing in wholesale houses, 700
Latham, Dr. P. W., on the synthesis of uric acid, 244; on some points in the pathology of rheumatism, gout, and diabetes, 626, 673, 723, 771, 817
Laudanum, death from an overdose of, 1050
Laudanum-tippling, 595
Lavers, Dr. T. J., on paralysis agitans, 142
Law and lunacy, 808
Lea, river, purification of the, 173; pollution of the, 414, 656, 701, 812, 1003, 1186
Leach, Mr. A., on the case of Mr. E. Bartlett, 968, 1017
Lead-poisoning, 504; from drinking-water, cases of, 306; by household utensils, 320; from mincing machines, 527
Lead-tremor, case of, 653

LECTURES.

ASHBY, Mr. H.:—
Clinical Lecture (Abstract of a) on the Connexion between Scarlet Fever and Heart Disease, 961

BARWELL, Mr. R.:—
Clinical Lecture on a Case of Thoracic Aneurysm treated by a Novel Method, 1058

BROWNE, Mr. E. A.:—
Introductory Lecture to the Course of Ophthalmology, delivered at University College, Liverpool, 238

MEDICAL SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND.—Madura foot; Milky fluid in the peritoneal cavity; Rupture of an intercranial vessel; Osteomalacia, 110—The surgery of the Suakim Expedition; Organisation of the medical department of an army corps, 158—Albuminometry and Esbach's tubes; Embolism of central artery of retina, 304—Ovarian displacements, 402—Dentigerous cyst; Perforating ulcer of stomach; Bright's disease, 493—Keeping perforation of the membrana tympani open; Radical cure of hydrocele; Therapeutic uses of the digestive ferments; Fetid expectoration from the lung, 691—Duties of medical officers of health; Muscular anomaly of right upper extremity; Nerve-supply of the short muscles of the thumb, 787—Villous disease of kidney and rupture of heart; Cancer of liver; Spontaneous rupture of heart, 928—Causation and treatment of pneumonia; Hyperpyrexia in rheumatic fever, 1070—Retroversion of the bladder, 1163
CAMBRIDGE MEDICAL SOCIETY.—Friedreich's ataxia; Embolism of central artery of retina, 67—Disease of finger-nails; Faith-healing; Unusual case of broken neck, 207—Salivary calculus of unusually large size; Retro-uterine hæmatocele; Tubercular meningitis following a blow on the head; Exostosis of great toe, 494—Inflammation of joints following injury to spine, 643—Encephalo-scirrhus of common bile-duct; Malignant disease of prostate; Aneurysm of arch of aorta; Occipital meningocele, 788
CHESTER MEDICAL SOCIETY.—Aborted ovum; Glioma of brain; Estimation of urea in urine, 306—A small mitral valve; Neuralgia of syphilis; Hæmophilia, 692
CLINICAL SOCIETY OF LONDON.—Desquamative prostatitis with hyaline casts; Cervical spina bifida; Myositis ossificans, 108—Ununited fracture of clavicle, with symptoms of writer's cramp; A new symptom of megrim and epilepsy; Chronic simple ulcers of stomach and duodenum; Complete recovery from amaurosis of malarial origin, 204—Universal alopecia; hysterical pyrexia; Meningitis of obscure origin, 351—Traumatic inguinal aneurysm; Aneurysm in stump; Intussusception of upper part of jejunum; Acute intestinal obstruction, 447—Sequelæ of small-pox, especially as affecting the speech; Baruria in a woman; Phosphorus necrosis of lower jaw, 543—Hernia cerebri treated by silver plate closing the opening in skull; Nervous tubercular ulceration of palate; Popliteal aneurysm in locomotor ataxy cured by pressure; Acute intestinal obstruction after ovariotomy, 639—Erythema nodosum and rheumatism; Peculiar cases of pneumothorax; Litholapaxy in a boy of ten, 739—Interstitial or subpleural laceration of lung; Gummata of liver; Hydatids of liver opening into right lung; Resection of knee for old-standing ununited fracture of patella, 878—Aneurysm of aorta and galvano-puncture; Rupture of aortic aneurysm into posterior mediastinum and abdominal cavity; Impaction of stone in one ureter, with atrophy of the other kidney, 975—Report of Albumen Test Committee; Aneurysm of hepatic artery; Treatment of nævus by excision; Suppuration in mastoid cells, with thrombosis of lateral sinus and septic embolism; Simultaneous inflammation of serous membranes, 1068
DEVONPORT AND PLYMOUTH MEDICAL SOCIETY. Exhibition of cases and specimens, 258
EPIDEMIOLOGICAL SOCIETY.—Diphtheria, 449—Cholera in fleets and ships, 642—Dissemination of scarlet fever by drinking the milk of diseased cows, 927
HARVEIAN SOCIETY.—Annual meeting and conversazione, 207—The neurotic treatment of catarrh; Animal vaccination; Cyanosis in newly-born children, 401—Chronic rheumatic arthritis of the hip-joint, 549—Compound fracture of the patella; Sprained joints, 642—Paralysis of tongue, palate, and vocal cord; Treatment of obscure forms of metrorrhagia, 689—Bulbar paralysis; "Nodding spasm"; Albuminuric retinitis; Left lateral hemiopia; Dislocation of crystalline lens, 833—Sudden death in pregnancy, parturition, and the puerperal state, 1022—Nerve-stretching for leprosy; Albumens of the urine, 1070
LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Thrombus; Antiseptics in operations on the eye; Strumous disease; Labio-glosso-laryngeal paralysis, with atrophic paralysis of the hands, 305—Cardiac hypertrophy and kidney disease; Defective or scanty menstruation; Distension of gall-bladder, aspiration; Injuries to joints; The mountain cure in heart disease; Pasteur's inoculations, 789
MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—Annual general meeting; Causation of follicular tonsillitis, 927
MEDICAL SOCIETY OF LONDON.—The Lettsomian Lectures, 65—Treatment of varicocele; Lardaceous hepatic disease; Athetosis, 109—Moot points in syphilis, 157, 252—Theory of fever; Pyæmia after removal of sarcoma from base of skull, 206—Subperiosteal resection for acute necrosis; Cerebral abscess and empyema, 303—Dystrophy of the thumb-joints; Excision of the elbow-joint, and tubercular testis; Tubercular leprosy; Pityriasis circinata; Congenital constriction of leg with perforating ulcer of foot, 352—Combined action of cocaine and nitrate of silver in superficial affections of the eye; Severe endocarditis, 400—General annual meeting; Spastic paralysis; Aneurysm of aorta, 492—Furneaux Jordan's amputation; Excision at hip-joint; Mediastinal tumour; Anæsthetic leprosy; Xanthelasma; Scleroderma, 545—Amputation of penis; Alveolar abscess with thrombosis of cavernous sinus, 593—Irritable brain and congestion of the brain in children; simple Pneumothorax, with rapid recovery, 641—Traumatic hydronephrosis; Relation of tonsillitis to scarlatina and diphtheria, 689—Bony union of fractured patella; Myxœdema with contractions; Spinal sclerosis and osteo-arthritis; Amputation of leg for sarcomata; Hereditary tremor, 741—Littre's hernia; Simple meningitis, 786
MEDICO-PSYCHOLOGICAL ASSOCIATION.—Quarterly meeting, 744
MIDLAND MEDICAL SOCIETY.—Mollities ossium; Foreign body in the œsophagus; Epithelioma; Hydronephrosis; Wrist-drop, 68—Naso-pharyngeal growths; Ophthalmoplegia externa cured by iodide of potassium; Athetosis, 256—Healed phthisical cavity; Anæsthesia of hand; Antipyrin; Flat-foot; Cyst of parovarium; Hemilateral myelitis, 495—Case of lead tremor; Brass-founder's ague; Ambiyopia and monoplegia; Aortic aneurysm; Spinal curvature, 693—Transfusion apparatus; Azoturia, 791—Loss of conjugate movements of the eyeballs; Paraplegia and anæsthesia of legs; Glioma of retina; Senile Cataract, 977
NORFOLK AND NORWICH MEDICO-CHIRURGICAL SOCIETY.—Suture of the ulnar nerve, 594
NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—Epithelioma of tongue; Trephining for traumatic epilepsy; Supra-pubic operation for removal of large calculus, 69—Aneurysm of the right subclavian artery; Leucocythæmia; Gastrostomy; Obstruction from gall-stone; Antiseptics, 257
NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—The treatment of congenital talipes equino-varus, 68
OBSTETRICAL SOCIETY.—Dr. Heywood Smith; The oblique pelvis of Naegele; Gastrotomy for extra-uterine gestation, 255—Removal of both ovaries during pregnancy, 353—Anatomy of labour; Sarcoma of vagina and uterus, 548—Contraction, inhibition, and expansion of the uterus; mitral stenosis in labour, 743—Elasticity, retraction, and polarity of the uterus; Serous perimetritis, 925—Artificial production of so-called lymphatic varix; Causes of difficulty in turning; Spurious hermaphroditism, 1222

Digitized by Google

OPHTHALMOLOGICAL SOCIETY.—Shrinking of conjunctiva; Amblyopia from bisulphide of carbon; Synchysis scintillans; Atrophy of iris; Meningitis after excision of eyeball, 253—Deposit of quinine in corneæ; Biniodide of mercury solution; Report on sympathetic ophthalmia; Cerebral hæmorrhage and optic neuritis; Glaucoma; Central blepharoraphy, 546—New formation of pigment on anterior surface of iris; Relapsing cyclitis; Herpes facialis; Hæmorrhagic glaucoma treated by trephining; Wound of eye followed by iritis serosa of the other eye; Central guttate choroiditis; Glaucoma treated by convex lenses, 742—Exophthalmic goitre, 923—Foreign bodies; Cholesterine in detached retina; Exophthalmic goitre; Detachment of retina; Embolism of central artery in puerperal septicæmia; Cataract extraction, 1221

PATHOLOGICAL SOCIETY.—Sarcoma of tongue; Malignant disease of œsophagus; Joint disease in animals; New growths in heart and viscera; Tubercular exfoliating cystitis; Aneurysm of mitral valve, 64—Colloid degeneration of the breast and omentum; Spontaneous fracture of urinary calculi; Diffuse sclerosis of brain in an infant; Large aneurysms; Post-nasal fibroma in a child; Stricture of rectum, 156—Intra-cranial tumours, 251, 349—Cancer of body of stomach; Cylindrical cancer of humerus; Dermoid cyst of tongue; Epithelial tumour of skin near rectum, 349—Congenital cystic kidney; Pistol-shot wound of cranium; Villous tumour of accessory thyroid; Cancer of thyroid; Ossifying sarcoma of radius; Aneurysm of septum ventriculorum; Congenital skin-tumour of sigmoid flexure, 445—Intra-cranial cyst; Acute nephritis in lambs; Hydatid of liver embedded in large syphilitic deposit; Valvular obstruction of ureter; Embolism of abdominal aorta; Septic aortitis, 687—Congenital fatty tumours of sole of foot and palm of hand; Abnormality of colon; Meningeal hæmorrhage due to aneurysm; Rheumatoid arthritis; Hydatid tumour of retro-vesical pouch; Thrombi in pulmonary artery, 831—Obliterative tracheitis and bronchitis; Pathological histology of hydrophobia; Granuloma fungoides; Hepatic abscess; Cancer of thyroid; Double intestinal stricture; Spinal abscess; Psoas abscess; Tubercular arteritis; Malignant growth of lip, with melanosis, 876—Adenoma of ovary; Adenoma of palate; Neuroma of parotid; Actinomycosis in man; Erythrasma; Mediastinal tumour; Peripheral neuritis; Duct papilloma of breast; Secondary epithelioma of jaw; Osteochondro-sarcoma of breast; Osteochondroma of thigh, 973

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Leucocytosis; Removal of tumour from brachial plexus, 107—Mortality in the medical profession; Tapetum lucidum, 201—Enteric fever at Suakim, 302—Thoracic aneurysm treated by the introduction of steel wire into the sac; Changes in bone and soft tissues after amputations, 399—Annual general meeting; President's address, 445—Harlequin fœtus; Cardiography, 491—Tuberculosis of the skin; Paracentesis for bronchiectasis, 591—Supra-pubic lithotomy, 637—Chemical pathology of respiration in cholera; Splenectomy, 739—Development of mammary functions by the skin of lying-in women; Paraplegia from Pott's disease, and its treatment by actual cautery, 830—Ligature of the larger arteries in their continuity; Congenital absence of hair, with atrophy of skin and its appendages, 922—Encysted and infantile hernia; Imbecility with choreoid movements; Treatment of stricture of urethra by electrolysis, 1020—Multiple neuromata; Pneumonia, 1114

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY—Extra-uterine fœtation; Pseudo-hypertrophic paralysis; Progressive muscular atrophy; Inflammation of tibia, 159—Extra-uterine fœtation; Calculi in kidney; Cases of lead-poisoning from drinking-water, 306—Cholesterine in retina; Carbolic acid poisoning treated by cocaine; Present position of therapeutics; Malignant disease of throat; fever, 790—Congenital tumours of orbit; Salivary calculus; Communication between stomach and transverse colon; Contamination of drinking-water with lead, 1163

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The housing of the working classes as it affects the status of medical officers of health, 109—On suction of sewer gases into service-pipes conveying drinking-water, a fertile causation of enteric fever, 593—Sanitary state of London poor districts, 690—Dr. Koch's gelatine peptone water test, 880

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—Difficulties of diagnosis in certain cases of cerebral tumour, 111—Stricture of urethra; Paroxysmal hæmoglobinuria, 791

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Cases of interest from the late war in the Soudan; Antiseptic surgery at the West London Hospital, 66—Bacteriology, 1022—Hereditary syphilis in infants, 1162

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.—Simple fracture of patella; Radical cure of hernia, 257—Amputation of breast for cancer; Paralysis following injection of iodoglycerine for treatment of spina bifida, 791

Medical Society of London, annual meeting at the, 492
——— students and infectious diseases, 937
——— surgery, 911
Medicament, a rough and ready, 1052, 1102, 1149
Medicine, three epochs in, 779; the martyrology of, 986
Medicines, safety in dispensing, 478
Medico-Psychological Association, 474; quarterly meeting at the, 744
Medulla oblongata, disease of the, and hemianæsthesia, 221
Megrim and epilepsy, a new symptom of, 294
Melbourne Hospital, 369
———, chair of pharmacology in, 380
Melsens, M. Louis, 989
Membrana tympani, keeping open perforation of the, 641
Memory, natural and artificial, 559
Meningeal hæmorrhage due to aneurysm, 832
——— and cerebral manifestations in mumps, 269
Meningitis, 409; of obscure origin, 352; tubercular, following a blow on the head, 494; simple, 787; cerebro-spinal, 893
Meningo-encephalocele, 34
Menstruation, defective or scanty, 789
Mental convalescents, after-care of, 952
Menzies, Dr. J. A., on diphtheria and pigeon keeping, 671
Mercury, effect of, on the blood, 173; subcutaneous injection of oxides of, 322
Mesentery, lipoma of the, 273; solid tumours of the, 375
Metritis in young girls, 125
Metropolitan Asylums Board, 228, 274; and the Eastern question, 163
——— Board of Works, the, on the ventilation of sewers, 316
——— Free Hospital, 956, 1003

——— Public Gardens Association, the, 32
Metrorrhagia, treatment of obscure forms of, 689
Mexican medical schools, 413
Mexico, mosquitoes in, 273; the nigua in, 846
Meynert, Mr. T., Psychiatry (review), 595
Mezger, Dr., and the Pope, 78
Micro-organisms, action of sunlight on, 225
Microzymes, the, 983
Middlesex, a new asylum for lunatics in, 843; and Herts combined districts, health of, 949
Midland Medical Benevolent Society, 1099
Midwifery case, curious complication in a, 382
——— forceps, a modified, 1024, 1149
Mile-end Old Town, sanitary state of, 171
Milk, a new fraud in, 458; adulteration, 600
Milk-tester, the hypodermic syringe as a, 274
Milroy, Dr. Gavin, obituary notice of, 425
Milton, health of, 1043
Mind and matter, 92
Mines Commission, the report of the, 798
Minnesota, public health of, 126

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

ANCOATS HOSPITAL, MANCHESTER.—Urethral stricture; perineal abscess; continuous dilatation; cure, 105

BRADFORD INFIRMARY.—Functional disease of the heart, 154

BURTON-ON-TRENT INFIRMARY.—"Crushed abdomen"; death on the third day; necropsy, 921

CASHEL UNION HOSPITAL.—Laryngotomy; recovery—Strangulated femoral hernia; operation; death from phthisis, 738

CHARING-CROSS HOSPITAL.—Transverse fracture of left patella; operation; cure, 300—Osteo-sarcoma growing from second cervical vertebra and pressing on spinal cord, 301—Self-inflicted bullet-wound, laying bare and traversing the brain; removal of bullet; recovery, 397—Acute chorea with pregnancy; induced premature labour; recovery, 689

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—Aortic regurgitation, with acute congestion of lungs, relieved by free bleeding, 490

CUMBERLAND INFIRMARY.—Fæcal accumulation causing symptoms of partial obstruction, 687

DUNDEE ROYAL INFIRMARY.—Hyperpyrexia occurring twice in the course of acute rheumatism; reduction of heat by cold baths; death; necropsy, 155

EDINBURGH ROYAL INFIRMARY.—Aphasia from injury; subsequent hemiplegia; trephining; death; necropsy, 398—Aneurysm of abdominal aorta, 490

EUROPEAN GENERAL HOSPITAL, ADEN.—Multiple abscess of the liver; death; necropsy, 1020

GREAT NORTHERN CENTRAL HOSPITAL.—Fracture of nasal and superior maxillary bones; necrosis and abscess with proptosis; removal of sequestrum, 972

GUY'S HOSPITAL.—Hydrophobia; death; necropsy, 635—Bullet-wound of forehead; division of left optic nerve; occasional epileptiform seizures; coma; death; necropsy, 971

INGHAM INFIRMARY, SOUTH SHIELDS.—Compound comminuted fracture of the patella; recovery without operation, 1162

KASHMIR MISSION HOSPITAL.—Abscess of kidney communicating with bowel; operation; necropsy, 201

KIMBERLEY HOSPITAL, CAPE COLONY.—Successful ligature of common iliac artery for aneurysm of external iliac, 444—Aneurysm of aorta simulating aneurysm of innominate; simultaneous ligature of common carotid and subclavian, ib.

KING'S COLLEGE HOSPITAL.—Compound fracture of the humerus implicating elbow-joint; recovery with useful joint, 154

LEEDS GENERAL INFIRMARY.—Cases of compound fracture, 874

LIVERPOOL INFIRMARY FOR CHILDREN.—Croupous pneumonia and gangrene of lung, 636—Multiple abscess of liver following impaction of a pin in the vermiform appendix, ib.—Caries of last dorsal and first lumbar vertebræ, with partial paraplegia and contracture of muscles of thighs, in a girl; cure without deformity, 830

LONDON HOSPITAL.—Severe urethral stricture treated by permanent supra-pubic drainage of bladder, 1161

MANCHESTER ROYAL INFIRMARY.—Ruptured femoral aneurysm in Hunter's canal; ligature of femoral artery; cure; subsequent death from heart disease; necropsy, 1113

MIDDLESEX HOSPITAL.—Three cases of uterine fibro-myoma; two removed by abdominal section, and one treated by the administration of ergotine, 62

MONTGOMERYSHIRE INFIRMARY.—Case of pregnancy with almost complete occlusion of vagina, 1068

MOUNT GAMBIER HOSPITAL, S.A.—Abscess of brain; cyst containing necrosed bone; death; necropsy, 786

NEWCASTLE-ON-TYNE INFIRMARY.—Large loose cartilage successfully extracted from the knee-joint of a patient aged eighty years, 302

NORTH-EASTERN HOSPITAL FOR CHILDREN.—Removal of portion of tracheotomy tube lodged in the right bronchus for two days, 250

NORTH STAFFORDSHIRE INFIRMARY.—Tumour of spermatic cord simulating hernia, causing sloughing of scrotum; operation; cure, 18

NOTTINGHAM GENERAL HOSPITAL.—Punctured wound of buttock, followed by traumatic aneurysm; operation; cure, 590—Extra-uterine fœtation; operation; recovery, 636

PENDLEBURY HOSPITAL FOR CHILDREN.—Ulceration into great vessels of neck, leading to hæmorrhage, in a case of scarlet fever; death, 301

QUEEN'S HOSPITAL, BIRMINGHAM.—Malignant disease of cæcum; necropsy, 348

RADCLIFFE INFIRMARY, OXFORD.—Excision of the thyroid gland, 829

ROYAL ALBERT EDWARD INFIRMARY, WIGAN.—Traumatic rupture of the urethra; perineal section; recovery, 540

ROYAL BERKSHIRE HOSPITAL.—Subacute myelitis, with calculus impacted in the ureter, 737

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—A case of osteo-malacia, 397

ROYAL SOUTHERN HOSPITAL, LIVERPOOL.—Two cases of ileus occurring in brothers; employment of tobacco; recovery, 1229

ROYAL UNITED HOSPITAL, BATH.—Two fatal cases of perforating ulcer of duodenum, 250—Excision of rectum for scirrhous cancer; recovery, 541

ST. BARTHOLOMEW'S HOSPITAL.—Double popliteal aneurysm; ligature of both femoral arteries; recovery, 489—Sarcoma of bladder; cystotomy; supra-pubic puncture, 737—Bullet wound of forehead; optic neuritis; partial recovery, 970—Idiopathic œdema of scrotum; sloughing of its greater portion; cellulitis and suppuration of abdominal wall; recovery, 1067

ST. GEORGE'S HOSPITAL.—Volvulus of ascending colon; death; necropsy, 828—Ovarian dermoid tumour in a girl of thirteen; rotation and commencing gangrene of cyst; ovariotomy;

Digitized by Google

recovery, 920—Exploration of the kidney for suspected calculus, 1112—Three cases of pyæmia, ending fatally; necropsies, 1219
ST. GEORGE'S AND ST. JAMES'S DISPENSARY.—Chorea and epilepsy, 16—Case of erythema nodosum, 785
ST. MARY'S HOSPITAL.—Contracted granular kidney; death; necropsy, 199
ST. OLAVE'S UNION INFIRMARY.—Recurrent proliferous cyst in a woman of sixty-three; ovariotomy twice within nine months, 1162
ST. THOMAS'S HOSPITAL.—Severe fractures; recovery, 105—Dislocation of left knee, ib.—Compound fracture of patella into knee-joint; suture of patella; recovery, 874—Tooth-plate impacted in the œsophagus; successful removal by œsophagotomy, 1019
SEAMEN'S HOSPITAL, GREENWICH.—Three hepatic abscesses; operations; recovery, 16—Necrosis and non-union following compound fracture of femur; amputation of thigh; recovery, 249—Two cases of varicocele; veins ligatured by kangaroo-tail tendon, ib.—Fractured patella treated by aspiration of joint, ib.—Surgical cases, 443—Ulcerative endocarditis; anomalous skin eruption; intestinal ulceration; death; necropsy, 785
TIMARU HOSPITAL, N. Z.—Two cases of compound depressed fracture of vault of skull; trephining; recovery, 875
UNIVERSITY COLLEGE HOSPITAL.—Stab in the abdomen with a carving-knife; examination of abdomen; uninterrupted recovery, 347
WEST BROMWICH DISTRICT HOSPITAL.—Rare injury to the pelvis; death; necropsy, 921
WEST LONDON HOSPITAL.—Poisoning by oxalic acid, followed by partial suppression of urine and acute nephritis; recovery, 347
WESTMINSTER HOSPITAL.—Small-celled sarcoma of femur; amputation at hip-joint; recovery, 539
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Surgical cases, 921
WOLVERHAMPTON GENERAL HOSPITAL.—Acute intussusception; inflation and injection of bowel; recovery, 63—Fracture (?) of thyroid cartilage; laryngotomy; recovery, ib.
WORCESTER GENERAL INFIRMARY.—Poisoning by chloroform; recovery after seventeen hours' unconsciousness, 398

Miscarriage, decapitation, 49
Missiles, stray, 274
Mitral disease, 218
——— stenosis, and lead poisoning, 33; in labour, 744
